				to assuring [BPA] is able to meet its public purposes and financial obligations for the long term.174 The DEIS does not contain any factual information to support the salience of customer concerns as justification for the selection of one alternative or measure over another. A 2018 analysis by Yakama Nation consultants compared BPA power costs to market power.175 The study concluded that: The day-ahead power market is volatile. It was more expensive than BPA power during parts of 2018 and long-term prices are uncertain. The day-ahead power market is relatively small, accounting for only about 10% of the regions energy needs. This will limit the number of utilities that could rely on this market and market prices would go up if there is more demand. BPA power contracts provide reliability and load-shaping services that are much more valuable than purchasing electricity in the day-ahead power market. BPA power is less expensive than constructing new power generating resources. For these reasons, it is likely that BPA will continue to be competitive and most utilities will renew their long-term contracts with BPA in 2028. 173 DEIS at 3-801. 174 DEIS at 3-842. 175 A copy of the analysis is included as Appendix C to these comments. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 43 The day-ahead market is volatile. For example, BPA power has generally been more expensive than day-ahead market power during the past few years. This changed dramatically, however, in July and August 2018. During those months, Mid-Columbia market prices spiked from $17 per megawatt hour to $70 per megawatt hour. These numbers were twice as high as BPAs prices. Day-ahead prices also exceeded BPA between 2012 and 2015 due to a 75% increase in market prices. Future prices for the day-ahead market are uncertain and could exceed BPA prices if natural gas prices go up or utilities increase demand on this market. Therefore, the day-ahead market price is not as stable as BPA power. BPA power, on the other hand, is more valuable and has less risk than day-ahead market power. Utilities can purchase electricity from BPA that is delivered to match a utilitys exact loads throughout each day; day-ahead market power must be combined with other services to precisely meet utility loads. BPA power is sold through long-term stable contracts, whereas market power is only available under short-term contracts subject to significant supply and cost risks. Consequently, the day-ahead market power is not as reliable and does not have the same quality as BPA power. The 2018 study analyzed the issue of BPAs competitiveness. The analysis describes how public utility customers must continue to purchase power from BPA through 2028 and considered the alternatives available to these utilities once their current BPA contracts expire. The study indicated that BPA power is of a higher quality and lower risk relative to market power. Furthermore, there is a significant range in the forecast for future market prices. Purchasing power from BPA is likely to cost half as much as purchasing power from new generating resources. A utility considering foregoing a long-term BPA contract would also need to weigh the risk that, if circumstances changed and the utility sought to return to BPA, it would only have access to BPAs Tier 2 power, which will be similar to market rates in the near term and the cost of new resources in the long term. It is also apparent that BPAs customers recognize that BPA will not lose utility loads through 2028. In its brief for a 2007 BPA rate case, the Washington Public Agencies Group (WPAG) stated fortunately for BPA, the current take-or-pay Regional Dialogue Contracts largely shelter it from price-induced reductions in load through FY 2028.176 These take-orpay contracts require utilities to pay for electricity from BPA whether or not they actually take power. In the brief, WPAG goes on to note that [u]nfortunately, for BPAs preference customers, it appears that due to [low natural gas prices, the rise of renewable energy, multiplying carbon-free initiatives, and reduced demand], including diminishing net secondary revenue and increasing fish and wildlife costs, this rate case will result in another substantial power rate increase, and yet another hit on BPAs perceived competitiveness. A key question here is what alternatives the utilities have opposed to purchasing power from BPA after 2028. The Yakama Nations study compared two potential alternatives for future utility purchases: day-ahead market power and purchasing a new generating resource. 176 BPA, ROD, 28. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 44 BPA Power versus Day-Ahead Market Power: Utilities could purchase electricity from the market rather than from BPA. This type of power generally consists of surplus energy from existing generating resources and non-firm hydroelectric power. Approximately 10% of the regions power (i.e., about 2,000 average megawatts in 2018) is sold in this market. The filings by the public utilities in the rate case referenced above assumed that purchasing priority firm power from BPA through long-term contracts is comparable to purchasing electricity from the day-ahead market. This is a fundamental flaw in the perceived competitiveness debate. Utilities have an obligation to meet their exact loads every millisecond of every day of every year. Electricity demand varies significant during the day, with typical peaks in the morning and late afternoon. Demand also varies by season and location. For example, demand to heat homes and other buildings is higher during the winter in cooler climates. Demand to cool homes and other buildings is higher during the summer in warmer climates. Utilities also must maintain the correct frequency (sixty cycles per second) to ensure that clocks and machinery run properly and power is available in emergency situations where a generating plant is disabled. Utilities can purchase all of these services from BPA. Utilities would pay additional costs for these load-shaping and reliability services (which are not reflected in the day-ahead market price) by purchasing from the day-ahead market. There are other important differences between purchasing power from BPA and the dayahead market. BPA offers twenty-year sales contracts that provide long-term supply certainty. BPA power comes from dependable resources because it serves its firm loads based on critical-water assumptions from reliable hydroelectric dams. BPA power is delivered through a region-wide transmission network. This reliability is valuable for the existing customers of public utilities and an important consideration for companies considering where to locate new operations. The day-ahead market, on the other hand, is short-term. The loss of a resource, other electricity supply disruptions, or an increase in economic growth which increases electricity demand can reduce how much electricity is available in the day-ahead market thereby increasing market costs. The cost of BPA priority firm power is generally stable during a two-year rate period.177 Utilities can evaluate the long-term risks of price increases from future maintenance of the federal dams, fish and wildlife costs, and other BPA programs with relative certainty. The chart included below as Figure 1 illustrates that BPA rates are projected to increase by about 3.5% per year between 2010 and 2020.178 177 There are some circumstances where limited rate adjustments occur to address higher costs. 178 See BPA, STRATEGIC PLAN 2018-2023 (2018) at 35. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 45 Figure 1 Utilities cannot expect the same level of stability from the day-ahead market. As noted above, the day-ahead market can be extremely volatile. Changes in the price of natural gas, output from the regions dams which vary by water year, the amount of surplus fossil-fired power (i.e., power available above what is necessary to meet long-term contracts), and economic growth can significantly affect supply and demand, impacting the day-ahead market price. If a large number of utilities chose to rely on the day-ahead market for future electricity supplies, it is likely that the increased demand would correspondingly increase market prices. As an indication of price volatility, the chart in Figure 1 shows that the day-ahead market has fluctuated between $20 and $35 per megawatt hour with a 75% increase between 2012 and 2015. This chart also illustrates that, during between 2010 and 2014, day-ahead market costs were higher than BPA priority firm power in 2010, 2013, and 2014. Not shown on this BPA chart are the average Mid-Columbia prices for 2008, which (according to a Council report) were 240% higher than prices in early 2018. 2018 provided a dramatic example of the of the volatility of Mid-Columbia prices. BPA reports that these prices were $16.65 per megawatt hour in June, $71.88 per megawatt hour in July, and $69.96 per megawatt hour in August.179 A utility that relied on the spot market in 2018 would have experienced an increase of more than 330% for those two months and paid twice the BPA rate. The 2018 price spike had a number of causes: a heat wave that affected the Pacific Cost, Nevada, and Arizona increased the demand for electricity to meet air conditioning loads; constraints in natural gas supplies for electricity generating plants in southern California 179 Information from the week ending September 29, 2018. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 46 increased prices; and wildfires reportedly threatened transmission lines. These types of events may increase in the coming years due to climate change, intensifying the risk of more price spikes. The Pacific Northwest also learned an expensive lesson in market price volatility in 2000. BPA had committed to serve additional electricity loads on the assumption that it could supply them with wholesale market power and that market prices would remain stable. When the wholesale market price of electricity on the West Coast jumped from approximately $30 to over $300 per megawatt hour, BPAs reliance on the wholesale market increased costs to utilities throughout the region by more than $1,000,000,000. Future market prices are also uncertain. In 2016, the Council prepared an analysis of future market prices which noted that the Councils Seventh Power Plan forecast for spot market prices range from an average of $25 per megawatt hour to an average of $68 per megawatt hour over the next twenty years.180 A chart from that analysis, included below as Figure 2, illustrates this projection.181 Figure 2 BPA Power versus New Resources: The other alternative available to utilities that do not want to renew contracts with BPA is to purchase new generating resources. The Councils Seventh Power Plan evaluated a range of potential new resources. A chart from that analysis, included below as Figure 3, shows that the levelized costs of energy from new primary resources in dollars per megawatt hour are significantly more expensive than purchasing from BPA.182 180 COUNCIL, SEVENTH POWER PLAN (2016) at 2-12. 181 Id. at Figure 8-1. 182 Id. at 13-3. 0 10 20 30 40 50 60 70 80 $/MWh (2012$) Year Historic Medium Low Fuel Price High Fuel Price Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 47 Figure 3 This chart considers commercially proven technologies that have the potential to be developed within a twenty-year planning horizon and play a major role in the regional power system. It shows that electricity from BPA costs less than half as much as the lowestcost new generative alternative. Importantly, these generation alternative costs do not include all the services included in power from BPA. For example, a utility or consortium of utilities that purchased a generating resource would also need other services to meet peak	make it more comparable. Specifically, Bonneville's average wholesale rate includes the cost of providing benefits to utilities with higher average system costs (approximately $250 million annually), transmission costs associated with serving loads in other balancing authority areas (approximately $100 million annually), energy efficiency programs and incentives (approximately $125 million annually), support to utilities with low densities (approximately $40 million annually), and support to utilities with eligible irrigation loads (approximately $20 million annually). The commenter suggests that because Bonneville's power products are an inherently better product, with assured supply and stable pricing, that competitive concerns are misplaced or not substantiated in the EIS. The competitive concerns discussed in the draft EIS stem from several factors discussed in Section 3.7. First, is the divergence of market prices from Bonneville's wholesale power rate. This, as just discussed, is not an apt comparison, and does not in and of itself create competitive pressure on Bonneville's power rates. However, coupled with this divergence in price, is a sustained series of rate increases that, over a decade, have increased Bonneville's power rates by over 35 percent. See Section 3.7.3.1, at pages 3-842-843 in the draft EIS. Added to these pressures is consistent and vocal concern from Bonneville's preference customers with Bonneville's long-term competitiveness. These concerns are not merely anecdotal. In the BP-16, BP-18, and BP-20 rate proceedings, Bonneville has had to defend its cost competitiveness in its Records of Decision. The common theme presented by some power customers in these proceedings is this: unless Bonneville proactively manages its costs and arrests the trajectory of continued rate increases, Bonneville will no longer be positioned as the supplier of choice in 2028. The commenter suggests that given the uncertainties of market supply, price, and the risk of losing Bonneville's preferred power, few customers would or should leave Bonneville for competitive reasons. Herein, though, lies the crux of the competitiveness concerns addressed in the EIS. Bonneville's public customers will have a choice in 2028 as to their future power supplier. See draft EIS Section 3.7.2.5, at pages 3-801-802. While price alone should not be the primary driver, there can be little debate that if Bonneville's power rates are substantially above market alternatives, Bonneville would face the real risk of losing load. Commenter presents a compelling case why power customers should not leave Bonneville for less valuable products, but none of these reasons compel any customer to remain with Bonneville after 2028. The competitive pressure of higher rates results in real impacts on the retail consumers of these utilities. The discussion of Social and Economic Effects of Changes in Power and Transmission for each Alternative (in Sections 3.7.3.4 through 3.7.3.7 and in Section 7.7) describes the impact on jobs. Section 3.18.3 and Chapter 7 describe the Environmental Justice implications of the alternatives. And finally, many public comments from individuals and public power customers describe the impacts rate increases would have on public power customers (see this Appendix). Faced with this uncertainty and the stated concerns by power customers that continued rate increases would affect their decision to remain with Bonneville, the EIS appropriately discusses the competitive risks presented by the Multiple Objective Alternatives, particularly those that place upward rate pressure on Bonneville's power rates. See draft EIS, Section 3.7.2.5, pages 3-801-802 and Section 3.7.3.1, at pages 3-842-843. To be clear, the EIS presents this risk in the appropriate context as a qualitative risk. See draft EIS, Section 3.7.3.1, at pages 3-842-843. The EIS does not dispute that under many scenarios Bonneville would continue to be the provider of choice. With regard to large retail customers seeking other power suppliers, the commenter is correct that there can be substantial risks and barriers that may make the choice to change power suppliers an uneconomical choice. For these reasons, the co-lead agencies have not attempted to quantify what this risk would be or at what price point Bonneville's power customers would leave Bonneville for other suppliers. Nonetheless, the consequence of even a small fraction of Bonneville's firm load diversifying to other suppliers is consequential. As discussed in the EIS, Bonneville's preference customers make up over 80 percent of its revenue. See draft EIS, Section 3.7.2.5, at pages 3-801-802. These customers commit, through their contracts and power rates, to pay Bonneville's costs. A loss of even a small amount of sales to this core customer group would leave Bonneville in the position of having to sell additional power on the wholesale market, (often at fixed or formulaic prices) exposing Bonneville to the very volatility in prices that the commenter notes. See draft EIS, Section 3.7.3.1, at page 3-843. In a world where Bonneville must rely on a shrinking group of firm customers from which to recover its fixed costs, the EISs description of risk to long-term investments (such as fish and wildlife funding) is both apt and appropriate.

				loads and load shaping requirements during each day (and variations each year, respond to emergencies, and provide other ancillary services. Therefore, generating resources do not appear to provide a competitive alternative to BPA power. Tier 1 Power Considerations: A utility considering leaving BPA would also need to consider the risk that, if circumstances change and it wanted to return to BPA, the utility will not likely have access to low cost BPA electricity from existing resources. This low-cost power is referred to as Tier 1 power. Ten years ago, BPA went through an extensive Regional Dialogue process. This resulted in BPA deciding to allocate existing federal low-cost power to existing public utility customers Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 48 by establishing a high-water mark for each utility: the maximum amount of the low-cost Tier 1 power that each utility can purchase from BPA. Additional electricity purchased above the high-water mark is sold from Tier 2, which is power from new resources that BPA would purchase to serve utility load growth. If a utility gave up its contract with BPA in 2028, it is likely that the utility would also give up the right to its respective high-water mark allocation for Tier 1 power; BPA would allocate this power to other customers; and any future purchases by the utility from BPA would be subject to the Tier 2 rate. Loss of Large Load Customers by Utilities under BPA Contract: Public utilities have expressed concern that some of their large customers might seek electricity service from less expensive supplies. There is anecdotal information that some regional manufacturing plants have closed because of market conditions. However, the actual total loads for BPAs preference customers have increased. A utility has several options if large customers threaten to move to a different supplier. First, the utility can charge for stranded costs associated with power supply contractual obligations or infrastructure that was built specifically to serve the load. These stranded costs can be significant, thereby altering the economics of changing suppliers. Second, the utility can adopt policies to address any added costs to serve loads which leave and then return to the utility. Third, the utility can make clear to the customer that the customer faces the same cost uncertainties and risks described above. Changes in BPAs Total Load: BPA has raised concerns that it faces flat-to-declining firm power sales.183 Information from BPAs quarterly business review shows that its gross sales declined by $32,000,000 (or 1.3%) in fiscal year 2017 compared to fiscal year 2014.184 The table included as Figure 4 below illustrates this change. Figure 4 However, by using a range of 2015 to 2017, the same data shows that BPAs gross sales have actually increased by $140,000,000 (or 5.9%). The table included as Figure 5 below illustrates this change. 183 STRATEGIC PLAN 2018-2023, supra, at 34. 184 BPA, QUARTERLY BUSINESS REVIEW (2018) at 14. (98 percent of 2017 gross sales were for load following, block, slice, and Tier 2 sales). In an email dated June 14, 2018, Kevin Owen at BPA stated that the heavy majority of gross sales are firm power. FY14 FY15 FY16 FY17 Change Percent $ 2,572 $ 2 ,399 $ 2,402 $ 2,540 $ (32) -1.3% BPA Gross Sales (millions of dollars) Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 49 Figure 5 The official Pacific Northwest Loads and Resources Study, referred to as the White Book, shows that total loads for BPAs preference customers have increased by 253 average megawatt hours (or 3%) over the past three years.185 The White Book lists loads for the upcoming operation year. Table 3-1 in each of the previous three White Books, which shows cooperatives, municipal utility, and public utility district loads. This table, included below as Figure 6, illustrates that total loads increased between 2015 and 2017.186 Figure 6 BPAs operating revenues also increased between 2015 and 2017.187 Revenue from the sale of electricity and transmission increased by $185,000,000 (or 6%). A table from BPAs 2017 Annual Report, included below as Figure 7, illustrates this increase.188 Figure 7 The 2017 Annual Report also shows a reduction in U.S. Treasury Credits of $24,000,000 over the same period. BPA receives these federal credits from its fish and wildlife program expenditures pursuant to the Northwest Power Act. The reduction in these credits appears to be the result of lower fish and wildlife spending. The Lead Agencies failed to adequately consider these competitiveness issues in the DEIS. The Yakama Nation contends that a complete analysis would have addressed the 185 BPA, 2018 PACIFIC NORTHWEST LOADS AND RESOURCES STUDY (2018). 186 The 2014 White Book did not include this data. 187 BPA, 2017 ANNUAL REPORT (2017) at 52. The 2017 Annual Report does not provide a breakdown of firm power revenues. 188 Id. FY15 FY16 FY17 Change Percent $ 2 ,399 $ 2,402 $ 2,540 140$ 5.9% BPA Gross Sales (millions of dollars) White Book 2015 2016 2017 Change Percent Cooperatives 1,968 1,974 2,057 89 5% Municipality 2,731 2,668 2,627 (104) -4% Public Utility Districts 4,546 4,768 4,814 268 6% Total 9,245 9,410 9,498 253 3% BPA Public Utility Average Megawatt Loads 2015 2016 2017 Change Percent Sales $ 3,256 $ 3,284 $ 3,441 $ 185 6% U.S. Treasury Credits $ 82 $ 77 $ 58 (24) $ -29% Misc. revenues $ 65 $ 72 $ 71 6 $ 9% Total $ 3,403 $ 3,433 $ 3,570 $ 167 5% BPA Operating Revenues (millions of dollars) Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 50 misconceptions driving utility concerns with respect to competitiveness. In turn, this would remove any impetus for BPA to cut costs on items such as its fish and wildlife program. The Lead Agencies should revise the power analysis in the FEIS to include the aforementioned points, updating the information as needed.	
6299	29	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	C. The Lead Agencies power analyses fail to adequately consider electric power generation issues. The Yakama Nation is unable to independently verify the Lead Agencies analysis with respect to changes in electricity generation in DEIS Section 3.7. The Lead Agencies should have employed a more collaborative and transparent process, compared to the DREW, that involved the Yakama Nation in developing the analysis. This would have better positioned the Yakama Nation to evaluate this section and allowed for the meaningful public comment required by NEPA. It appears that the Lead Agencies analysis relies on the resource portfolios from the Councils Pacific Northwest Electric Power and Conservation Plan. The Lead Agencies should update the analysis based on the most current information being used for the upcoming 2021 Power Plan. Once the Lead Agencies update the analysis using this information, the Lead Agencies should use this analysis as a high-cost case. For a low-cost case, the Lead Agencies should incorporate, with any necessary updates, the analyses and recommendations from Energy Vision for the Columbia River.189 This draft document identifies actions that can save regional ratepayers more than $1,300,000,000 per year, reduce adverse impacts to salmon and other fish and wildlife, reduce climate changecausing emissions, and make BPA more resilient to changes that could affect its financial health. It emphasizes a diverse and reliable energy resource mix that would lower energy costs while helping to recover salmon and resident fish populations. Section 3.2 of Energy Vision for the Columbia River describes recommendations to improve energy efficiency and identifies low-cost energy savings of 1,000 average megawatts per hour above the conservation targets in the Councils Pacific Northwest Electric Power and Conservation Plan. Section 3.3 describes recommendations to increase the development of renewable resources. These analyses and recommendations are essential to a cogent power analysis in the FEIS and to the appropriate set of measures in a Preferred Alternative.	The Draft EIS uses high quality, recent information available to fully assess the economic impacts under each Multiple Objective alternative in a consistent and defensible manner. The Draft EIS uses resource information from the Northwest Power and Conservation Councils (Council) Seventh Power Plan and Mid-Term update. Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821; and Appendix H, Power and Transmission, at Section 2.2 in the Draft EIS. When information from the Council's Seventh Power Plan was clearly inconsistent with forward-looking expectations, Bonneville included additional sensitivity analysis to both qualitatively and quantitatively assess the impacts under each Multiple Objective alternative. For example, cost data for batteries under MO3 were sourced from metrics provided by the Council, which are complete and can be included in reference plant information contained in the forthcoming Eighth Power Plan. Additionally, the coal sensitivity analysis addresses additional planned or anticipated coal retirements which were not yet known when the Seventh Power Plan was created. Consistent with the comment, publicly released draft information, such as updated prices for solar and battery storage, from development of the Eighth Power Plan is included as rate sensitivities in the Final EIS. The comment suggests that additional energy efficiency should be assumed in the EIS, beyond what is achieved in the Councils Seventh Power Plan. All cost effective conservation identified by the Councils Seventh Power Plan is included in the load forecast. EIS, Appendix H, Power and Transmission, Section 2.2, H-2-3 in the Draft EIS. Under Washington and Oregon law, all cost effective conservation must be acquired regardless of the status of the Federal Columbia River Power System (FCRPS). Therefore, conservation was not considered a potential resource replacement. The EIS analysis considers that all energy efficiency assumed in the Councils Seventh Power Plan is appropriate and, likely aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings from efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as in MO3. The CRITFC's draft Energy Vision document is discussed in more detail in other comments from the Yakama Nation (please see responses to comments under Letter 6299), and from CRITFC (please see responses to comments under Letter 31775). Many of the elements of this draft document are incorporated in the EIS.
6299	30	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	D. The Lead Agencies power analyses fail to adequately consider the impact of electricity production on fish and wildlife resources. As described in the Energy Vision for the Columbia River the day-to-day and seasonal operations of the hydroelectric system to meet peak and seasonal electricity load requirements cause fluctuations in river levels. These fluctuations have the potential to destroy populations of salmon and other important fish species. Although changes in operation levels can lessen the frequency and severity of these occurrences, their effects are still significant. 189 TREATY TRIBES, ENERGY VISION FOR THE COLUMBIA RIVER (2013). Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 51 Hydropower is used to serve peak loads because dams are capable of reacting to demand by quickly putting more or less water through the turbines that generate electricity. However, this practice kills millions of juvenile salmon each year. During certain times of the year, so much water may be drawn down to generate electricity that salmon redds (i.e., gravel nests where salmon lay eggs) are uncovered or dewatered. This destroys the salmon eggs. Daily fluctuations change river water levels and, where water levels are reduced, juvenile fish that feed and live near shore may become stranded and perish. Decreased nighttime flows caused by lower electricity demand interrupts fish migration. Fluctuations in reservoir levels injure resident fish by reducing nutrients and dewatering habitat and food supplies. The water held behind storage dams for power generation would, under natural conditions, be flowing in the river and therefore aid the swift and timely downstream migration of young salmon. The recommendations in Energy Vision for the Columbia River are meant to reduce these impacts while at the same time decreasing costs for ratepayers. The Northwest electricity system has historically relied on the CRS to serve peak loads; the underlying assumption has been that running more water through the generators was a low-cost means of meeting peak requirements. This assumption ignored the other costs of serving peak loads. Energy Vision for the Columbia River found that BPA charged between $0.028 and $0.037 per kilowatt hour for wholesale power during high-load hours. This analysis showed that the costs of delivering (i.e., transmitting and distributing) peak electricity are more than twenty-five times higher than the actual generation cost of such energy.190 As described in detail in Energy Vision for the Columbia River, the cost of delivering for the highest 15% of peak energy to consumers ranged from $0.79 to $1.19 per kilowatt hour in 2013.191 The average retail consumer paid about $0.08 per kilowatt hour for delivered electricity.192 Thus, these peak delivery costs were more than ten times the total-average electricity costs. The cost of serving the very highest peak load ranged from $80 to $120 per kilowatt hour: one thousand times higher than average consumer costs.193 All of these costs become melded together in ratemaking, meaning that consumers are not able to easily discern the costs from different patterns of use. CRITFC estimated that reducing peak energy use could save consumers approximately $800,000,00 per year in planned expansions of the delivery system.194 An update of the analyses in Energy	The effects of load following and flow changes were incorporated into the ecological models used to analyze the CRSO. The alternatives analyzed included variations in withdrawal rates, flow change rates, spill level changes among many other variations that affected both power and fish and wildlife resources. Those effects are included in the results for the No Action Alternative, the 4 Multi-objective alternatives, as well as the Preferred Alternative. In nearly every instance, with the exception of MO2 which had operations that were intentionally designed to increase power production, the limits and restrictions on draw down rates and flow changes that are currently in place to prevent stranding or desiccation of redds are modeled to continue under the NAA, the MOs and the Preferred Alternative. The effects of load following and flow changes were incorporated into the ecological models used to analyze the CRSO. The alternatives analyzed included variations in withdrawal rates, flow change rates, spill level changes among many other variations that affected both power and fish and wildlife resources. Those effects are included in the results for the No Action Alternative, the 4 Multi-objective alternatives, as well as the Preferred Alternative. In nearly every instance, with the exception of MO2 which had operations that were intentionally designed to increase power production, the limits and restrictions on draw down rates and flow changes that are currently in place to prevent stranding or desiccation of redds are modeled to continue under the NAA, the MOs and the Preferred Alternative. The comments in the draft Energy Vision for the Columbia River (2013) include suggestions to reduce the within-day fluctuations such as time-of-use pricing, increasing power storage, or fuel switching. Bonneville's wholesale power rates have peak-demand charges; however time-of-use metering for retail use is controlled by the individual utilities serving retail customers. Bonneville's Energy Efficiency group is actively working on energy efficiency programs to address both total energy and peak demand. The EIS acknowledges that technology including storage technology is evolving. While these suggestions in the draft Energy Vision for the Columbia River would serve to reduce fluctuations in energy demand, the suggestion in the report to develop more solar and wind power can increase the fluctuations in energy needs as these are variable generators. Future technological improvements or coupling these resources with storage may counteract the increase in power fluctuations. While the EIS acknowledges these potential developments, they are not currently available and were not included in the EIS modeling.

				Vision for the Columbia River and implementation of its recommended actions is pertinent and important to the development of operations that reduce adverse impacts to fish populations consistent with obligations to the Native Nations while reducing costs for ratepayers.	
6299	31	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	E. The Lead Agencies power analyses fail to address actions to increase energy efficiency and reduce costs. 190 Id. at 8. 191 Id. at 9. 192 Id. 193 Id. 194 Id. at Appendix A. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 52 Based on the analyses in Energy Vision for the Columbia River, the Council determined that efficiency programs cost utilities approximately $18 per megawatt hour.195 This is less than half of the cost of new generating resources. These programs would minimize the regions costs of meeting additional electric energy demands. According to the Council, the region had saved five thousand megawatts since 1978 through energy efficiency programs, codes, and standards.196 These actions amounted to $3,100,000,000 in savings for the regions consumers in 2011. The implementation of appropriate conservations measures as part of an appropriate Preferred Alternative would surpass the conservation targets in the Northwest Conservation and Electric Power Plan and lead to an overall reduction in operating costs, there is a considerable amount of business incentive and public interest in energy efficiency today that did not previously exist. Customers are requesting green certifications and businesses are routinely marketing products with zero carbon footprints. The reduction in costs and demand would shift the relationship between the costs of fish and wildlife conservation and overall power rates. The regional 2011 conservation savings amounted to 277 average megawatts, 57 megawatts ahead of the goal for that year and about equal to the 2014 target. Oregon and Washington were poised to upgrade energy efficiency codes. Conservation budgets were increasing at private utilities. Significant portions of American Recovery and Reinvestment Act funding was geared toward energy efficiency. BPA adopted tiered rates were new loads were served at market costs rather than a melded rate. Finally, BPA issued a request for proposal to develop industrial conservation potential. Energy Vision for the Columbia River cited other analyses indicating that past studies by the Council had significantly underestimated energy efficiency and conservation potential.197 The study reviewed two papers to address this issue. The first paper, Beyond Supply Curves by two Energy Trust of Oregon staff and two Council staff, suggested that new technologies can significantly increase the amount and reduce the cost of energy efficiency measures.198 For example, the high efficiency windows referenced in the Councils 2005 plan are 12% more efficient than what was assumed in the Councils 1983 plan. Also, costs for energy efficiency technology become more competitive as that technology is more commonly used: the costs of compact fluorescent lamps dropped from the $12 per bulb estimates in the Councils 1991 plan to $3 per build estimates in the Councils 2005 plan. The second paper, Extreme Efficiency: How Far Can We Go If We Really Need To?, by David Goldstein for the American Council for an Energy Efficient Economy, noted that many current methodologies are excessively conservative if the goal of policymakers is to meet aggressive climate change emission reduction goals.199 Goldstein documented systematic biases that result in low potentials for energy efficiency: 195 Id. at 15. 196 Id. 197 Id. 198 FRED GORDON ET AL., BEYOND SUPPLY CURVES (2008). 199 DAVID GOLDSTEIN, EXTREME EFFICIENCY: HOW FAR CAN WE GO IF WE REALLY NEED TO? at 10-44. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 53 1) subjecting efficiency measures to a criterion of proof beyond a serious doubt; 2) assuming arbitrary realization factors less than 100% due to questions regarding social acceptance of energy efficiency; 3) implicit assumptions that a lack of research on the cost or feasibility of a measure means that it should be excluded from a study; 4) failure to consider system integration; 5) assumptions that technological process ceases and further improvements are not possible once known efficiency measures are implemented; and 6) reliance on projected costs of efficiency without look at realized costs, which are ultimately are always lower where data has been available.200 These considerations signal that conservation estimates are frequently too conservative. Unfortunately, there are significant costs to these conservative estimates. Energy Vision for the Columbia River offered the following example, which focused on only one conservative assumption by the Council. In the Sixth Power Plan, the Council de-rated the available conservation by 15%, assuming that no more than 85% of the technically feasible and cost-effective savings can be achieved.201 De-rating the amount of achievable energy efficiency by 15% represents approximately 1,000 average megawatts of low-cost power that are not included in conservation targets. A simple calculation of the 2013 value (marginal resource costs minus cost of conservation multiplied by 1000 average megawatts202) shows that the value of this additional conservation is approximately $500,000,000 per year. If one assumes that these savings are phased in over the life of a twenty-year power plan, the additional savings could total $5,000,000,000 by 2030. Given the significant value of additional energy efficiency, the Lead Agencies should work with the Council to analyze these savings for the FEIS. Such an analysis would likely further reduce the costs of the alternatives included in the EIS and allow appropriate focus on fish and wildlife conservation and restoration.	The comment suggests that additional energy efficiency should be assumed in the EIS, beyond what is achieved in the Northwest Power and Conservation Councils (Council) 7th Power Plan. The EIS analysis considers that all energy efficiency assumed in the Councils 7th Plan is appropriate and, likely, aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings form efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as in Multiple Objective (MO) Alternative 3. The Councils 7th Power Plan is the current power plan and included conservation targets over the 20 year period of the plan, and is the source of the data used in the EIS. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821 and Appendix H, Power and Transmission, at Section 2.2. The analysis in the EIS includes all energy efficiency in the Councils plan through 2022. See Appendix H, Power and Transmission, Section 2.2, H-2-3 in the draft EIS. Northwest utilities are required by law to acquire all cost effective conservation regardless of the status of the four lower Snake River projects. Therefore, if the amount of cost-effective energy efficiency increases, utilities are required to achieve it regardless of the status of the Federal Columbia River Power System.
6299	32	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	F. The Lead Agencies power analyses do not account for the role of low-income weatherization programs in the affected environment and benefits of increased energy efficiency in framing alternatives and assessing impacts. Tribal communities include many low-income families and individuals. For example, on the Yakama Reservation in 2013, the percentage of families living below the poverty level was 42% (four times higher than the average for non-Tribal families in the State of Washington); the winter unemployment rate was over 70%; and the per capita income was $5,700 per year (less than half the average for non-Tribal communities).203 As a result, much of the housing in these communities is substandard. Often, Tribal elders and other individuals who require safe homes are those who live in substandard housing. Weatherization programs can provide basic repairs needed for energy savings to be effective. 200 Id. at 10-4610-51. 201 COUNCIL, SIXTH POWER PLAN (2010) at 4-15 202 Id. at 10-4. 203 See pg. 59, infra. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 54 For completeness of the analysis, Lead Agencies need to account for the effects of lowincome weatherization programs on the cost analyses in the FEIS. Such programs would increase energy efficiency potential and further the Lead Agencies environmental justice responsibilities consistent with E.O. 12898 and related federal guidance.	The comment suggests that additional energy efficiency should be assumed in the EIS, beyond what is achieved in the Councils Plan. The EIS analysis considers that all energy efficiency assumed in the Councils 7th Plan is appropriate and, likely, aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings form efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as in MO3.The EIS analysis considered that all energy efficiency assumed in the Councils 7th Plan is appropriate and, likely, aggressive. The EIS included all cost-effective conservation, including weatherization, commercial building retrofits, and other energy efficiency programs, identified by the Northwest Power and Conservation Council in the 7th Power Plan, which is the current power plan. See Appendix H, Power and Transmission, Section 2.2, H-2-3. Cost effective conservation in the region will be acquired pursuant to current law regardless of the operation of the CRS, i.e., regardless of which alternative is selected. Therefore, weatherization, commercial building retrofits, and other energy efficiency programs were not considered for additional energy efficiency for the action alternatives to avoid double-counting.
6299	33	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	G. The Lead Agencies analyses do not account for the role of energy efficiency programs for commercial buildings in the affected environment and the comparability of impacts from reasonable alternatives. Energy efficient commercial buildings offer enormous potential savings. Lighting, appliances, and, most critically, heating, ventilation, and air-conditioning (HVAC) systems, appliances designed for energy efficiency can significantly reduce power costs. The complexity of HVAC systems means that they need continuing attention to remain efficient and tuned to the tasks for which theyre designed. All new buildings should require certification processes to assure that HVAC systems are operating properly and efficiently. Most commercial buildings rely on programmable but unmaintained thermostats. Many of these buildings HVAC systems are operated as if they were constantly occupied. Better scheduling can result in energy cost savings of 30% to 40%.204 Smart Grid technologies and strategies that enable a utility to essentially dispatch loads behind customers meters will more easily capture such savings. The Lead Agencies should adequately consider potential savings from energy efficient commercial buildings when considering energy costs in the FEIS. Furthermore, a regional concerted effort to facilitate these savings is potentially a mitigation action.	The EIS included all cost-effective conservation, including weatherization, commercial building retrofits, and other energy efficiency programs, identified by the Northwest Power and Conservation Council in the 7th Power Plan, which is the current power plan. Appendix H, Power and Transmission, Section 2.2, H-2-3. Cost effective conservation in the region will be acquired pursuant to current law regardless of the operation of the CRS, i.e., regardless of which alternative is selected. Therefore, weatherization, commercial building retrofits, and other energy efficiency programs were not considered for additional energy efficiency for the action alternatives to avoid double-counting. The EIS analysis considered that all energy efficiency assumed in the Councils 7th Plan is appropriate and, likely, aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings from efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as in MO3.
6299	34	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	H. The Lead Agencies power analyses fail to adequately consider loss of load probability issues. Energy Vision for the Columbia River identifies strategies to reduce peak loads and improve system reliability. This includes recommendations to site strategically located resources, address emergencies and dry year strategies, and decrease peak demands.205 In addition, the Council is evaluating demand response as part of its preparation of the 2021 Power Plan. A recent Council staff paper identifies 3,335 megawatt hours of potential demand response by 2041.206 The Lead Agencies should update the loss of load probability analysis in the FEIS based on information from Energy Vision for the Columbia River and the 2021 Power Plan.	The EIS conducts a comprehensive evaluation of Loss of Load Probability (LOLP) for the Multiple Objective alternatives. Appendix H, Chapter 2, Power Supply and Replacement Resources; and Appendix J, Chapter 4, System Reliability in the Draft EIS provide additional details on the power reliability analysis and LOLP modelling. The LOLP analysis is the result of 6,160 simulations. The EIS analysis considers that all energy efficiency assumed in the Northwest Power and Conservation Council's (Council) Seventh Power Plan is appropriate and, likely aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings from efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Seventh Power Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as in MO3. All cost-effective conservation (energy efficiency) as identified by the Council is included in the No Action alternative and is expected to be implemented regardless of which alternative is selected. See Appendix H, Power and Transmission, Section 2.2, H-2-3 in the Draft EIS. Regarding demand response, 600 MW of demand response was included in each renewable replacement resources portfolio, consistent with the Council's goal in the Seventh Power Plan. Section 3.7.3.1, Demand Response Analysis for CRSO, at page 3-837 in the Draft EIS; Section 3.7.3.5, at page 3-904. This may include load dispatch, and smart appliances, two components mentioned in the Columbia River Inter-Tribal Fish Commissions 2013 draft Tribal Energy Vision.
6299	35	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	I. The Lead Agencies power analyses fail to adequately consider cost issues. The Lead Agencies replacement scenario associated with the dam breaching analysis is almost exclusively reliant on a single renewable energy resource: solar power backed up by 204 ENERGY VISION FOR THE COLUMBIA RIVER, supra, at 19. 205 Id. at 3.4, 3.5, Appendix A. 206 COUNCIL, DRAFT DEMAND RESPONSE SUPPLY CURVES FOR 2021 Plan (2020). Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 55 batter storage. This narrow-focused reliance means that the Lead Agencies failed to consider alternative replacement resources such as wind power and other low-cost alternatives addressed in these comments. A broader and more complete analysis in the FEIS is necessary to ensure a comprehensive evaluation of the alternatives and the impacts associated with those alternatives.	The EIS describes the replacement resources that would be needed to maintain regional reliability at the No Action Alternative level based on two potential replacement portfolios: one based on renewable resources and another based on natural gas resources, which are generally the least cost means to maintain reliability (see Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS). To avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council in their 7th Power Plan (7th Power Plan, page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821 and Appendix H, Power and Transmission, Section 2.2 in the draft EIS. Although the use of storage technologies is considered a long-term resource of the 7th Power Plan and not a primary resource, it has become more commercially available since the release of the 7th Power Plan and was examined in the EIS. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907. Storage will likely be considered a primary resource in the Councils 8th Power Plan. The comment is correct that solar power was found to be the most cost-effective renewable resource for each alternative that required replacement resources; however, the EIS did evaluate the cost-effectiveness of all primary technologies identified by the Council including wind. For all portfolios, the most cost-effective conventional resource was natural gas and the most cost-effective renewable option was solar. See draft EIS, Section 3.7.3.5, Table 3-166. Wind was not selected because of its lower reliability benefit-to-cost ratio in terms of its contribution to lowering the Loss-of-Load-Probability (LOLP) versus the cost of the resource. However, wind was selected as an additional potential resource in the rate sensitivity

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					analysis for replacing the full capability of the four lower Snake River dams. See draft EIS, Section 3.7.3.5, Potential Replacement Resources and Associated Costs, pages 3-907-908. These two options, the least-cost conventional portfolio and the zero-carbon portfolio, represent a reasonable range of costs for replacement resources. In response to this and other public comments, Appendix H, Section 2.2 in the final EIS includes a more detailed description of how replacement resources were selected.
6299	36	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	J. The Lead Agencies power analyses fail to adequately contextualize rate issues. Reducing costs will reduce rate impacts. This will promote equitable treatment of fish and power interests. Once the Lead Agencies revise the power generation analysis, as described above, the rate impact analysis must be adjusted accordingly. The Lead Agencies should also add context to the rate impact analysis. The Lead Agencies state that current retail rates are 22% below the national average.207 The FEIS should analyze retail rates for each alternative, including the Preferred Alterative, relative to the national average. Moreover, an effective rate analysis will consider the effect of rate changes within the context of the dams role in the impairment of Tribal communities. For example, average retail rates will increase by 1.6% to 3.6% under MO3.208 With regard to MO4, the Lead Agencies describe the upward pressure on retail electricity rates and conclude that [t]hese expenditureswould, on average, account for 1.737 to 1.742 percent of household income. This represents a .018 to 0.31 increase in the percent of income spent on electricity relative to the No Action Alternative.209 The Lead Agencies need to evaluate these impacts relative to the economic effects on Tribal communities. These effects as discussed in depth in the Economics section of these comments. This evaluation would bolster the Tribal Interest discussion in DEIS Section 3.74, which ignores such effects.210	The EIS provides context regarding the relatively low power rates of the region compared to national averages in Section 3.7.2.5, Regional Retail Electricity Rates in the draft EIS. The EIS does not compare all rates under the alternatives to the national average instead compares them to the No Action Alternative to determine potential effects of each alternative, consistent with the Council on Environmental Quality's Implementing Regulations for the National Environmental Policy Act, and associated guidance as well as the NEPA implementing regulations from the Corps, Reclamation, and Bonneville. The Environmental Justice analysis, Section 3.18.3 and Chapter 7 provides further detail on potential disproportionate effects including those to Tribal, low-income, and minority populations. To present context regarding the role dams play in the impairment of Tribal communities and to ensure potential impacts on Tribal communities were represented as accurately as possible, Appendix P in the draft EIS presents first-hand Tribal perspectives that were provided by 11 regional Tribes, including the Lower River Tribes, on the operations and maintenance of the CRS. Section 3.17 summarizes these perspectives on the importance of the Columbia River basin resources and landscapes to Tribes, and the potential impacts of the CRSO EIS alternatives. The commenter is correct that the rate impacts are not addressed in the Draft EIS Section 3.7.4 Power Generation and Transmission Tribal Interests. However, rate impacts on Tribal communities are addressed in the Environmental Justice sections (Section 3.18 and Chapter 7). As discussed in Section 3.18.3, under the No Action Alternative and each of the MOs, energy burdens are already likely unaffordable for Tribal households with incomes below the Federal poverty level. Based on available research, the Environmental Justice analysis uses a threshold of 6 percent of a households annual gross income for affordability for energy (Fisher Sheehan & Colton 2015). Upward rate pressure resulting from the MOs could exacerbate these impacts on low-income Tribal households. Under the Preferred Alternative the Bonneville wholesale power rate pressure is estimated to be 2.7 percent relative to the No Action Alternative. A portion of that rate pressure has already been incorporated into the BP-20 wholesale power rates; and, the remaining rate pressure likely falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control.
6299	37	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	K. The Lead Agencies power analyses fail to adequately consider transmission line issues. Energy Vision for the Columbia River identifies strategies to reduce transmission needs and save costs. The savings identified are larger than the added costs identified by the Lead Agencies in the DEIS. An adequate analysis will integrate cost reduction cost reduction measures with regard to transmission line issues into the alternative development, impact assessment and mitigation provisions of the FEIS.	Bonneville is aware of the Draft Energy Vision for the Columbia River cited by the commenter. This document was developed by external parties, and based on discussions with the Yakama Nation, it has not been finalized. Much of the discussion of transmission constraints and other issues in the Draft Energy Vision document address issues that are outside of the scope of the EIS. The EIS relied on multiple transmission models to assess potential transmission costs and congestion as described in Section 3.7.3.1, Methodology. These include evaluating transmission system congestion and the need for any system reinforcement and new transmission infrastructure. The EIS incorporates two key aspects of transmission congestion. First, by identifying a set of replacement resources that are projected to meet the key metric of maintaining the loss-of-load-probability of the existing power system, the EIS provides an initial perspective as to whether there are additional reliability impacts to the overall power and transmission systems. Second, by evaluating potential congestion from the shift of Columbia River System generation to the replacement resources, the draft EIS does begin to identify, or flag, critical paths on the system where there may be changes either increases, or decreases in potential congestion from an interconnection-wide least cost perspective. The only transmission reinforcement project proposed as a result of the CRSO EIS alternatives was under Multiple Objective (MO) Alternative 3 associated with the breaching of the four lower Snake River dams, namely Ice Harbor. As discussed in the draft EIS in the Bonneville Transmission System Reliability and Operations subsection in Section 3.7.3.5, and in Section 3.2.2 of Appendix H, prior to evaluating the impacts of potential breach of Ice Harbor Dam, Bonneville had identified the need for a transmission reinforcement project just beyond the 10-year planning horizon (2018-2028) to maintain reliable load service including to accommodate load growth, to the Tri-Cities area and to support transmission operations and maintenance. The base need for the project would arise independent of removal of the generation at Ice Harbor. However, the timing of the reinforcement is very dependent on when Ice Harbor generation might be breached and would be needed immediately. As such, the transmission analysis considered the speed up of the timing for the need for the reinforcement project as a result of dam breaching under MO3 by including the costs of the project starting at the time the generation from Ice Harbor would be removed from the system. This reinforcement would help ensure reliable service to the Tri-Cities load. The generation at Ice Harbor also allows Bonneville to take lines out of service for planned maintenance and other operational reasons without affecting reliable service to the Tri-Cities area in Washington. The inability to take lines out of service for maintenance and to respond to operational constraints, such as the loss of a transmission line, could increase risk to transmission system reliability and result in loss of load to the Tri-Cities area.
6299	38	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	A. The Lead Agencies economic analyses fail to consider the best available information. The 1999 and 2019 ECONorthwest studies provided detailed and comprehensive analyses of the new costs, reduced costs, and economic benefits of Snake River dam removal, including consideration of increases and decreases in employment.211 These studies also identify measures to mitigate any adverse economic impacts. The 2019 study summarized other recent research that showed significant benefits from actions comparable to MO3. While the Lead Agencies reference some of these additional studies in the DEIS, the Lead Agencies dismiss, ignore, or omit them from further analysis without clear justification. The Lead Agencies did not appear to put forth the requisite effort to properly update their analyses in light of these studies or subject their analyses to peer review or a collaborative and transparent process. As noted in the 2019 ECONorthwest study, the federal General Accountability Office (GAO) reviewed a 2002 EIS from the Corps and found that the economic studies therein were fraught with errors, mistakes, and miscalculations, and used invalid assumptions and outdated data. GAO concluded that the errors caused several [Corps] studies to understate costs, overstate benefits, and not allow for a reasonable basis for decision making. As described in these comments, the Lead Agencies approach in the DEIS appears similarly flawed. To the extent that the DEIS understates costs and overstates benefits, it provided an uninformed analysis. Furthermore, the Lead Agencies fail to consider pertinent studies and data in their analyses. But for the truncated review schedule for the DEIS, the requisite professional economic analyses could have been assured through review by a wholly independent scientific body such as the Councils Independent Economic Analysis Board. The deficiencies can be corrected accordingly and will produce a more defensible FEIS.	The commenter mis-characterizes the GAO analysis that was done on the Corps' document. GAO reviewed the Draft EIS (1999) before it was revised and finalized in response to GAO and Independent External Peer Review. GAO did not review the final EIS. The key finding from that GAO report on that Draft EIS was that the "The Corps conducted a comprehensive EIS process that generally adhered to procedural requirements of the relevant federal laws and other guidelines for conducting an EIS" This EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. A summary table in Section 7.4 has been added to provide a concise description of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a number of resources. Regarding passive use values, Section 3.15.2.2 of the EIS describes the ECONorthwest study, highlighting the objective and approach to estimating willingness-to-pay for salmon restoration. Consistent with this comment, the EIS describes that the results of the study are designed to reflect the value people hold for restoring salmon populations and therefore have limited applicability to the benefits of the CRSO alternatives. The ECONorthwest analysis and the EIS employ different analytical frameworks and rely on different findings with respect to the outcomes of breaching the four lower Snake River dams. First, the ECONorthwest report applies a cost-benefit analysis framework, emphasizing monetization of all categories of impacts. Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on fish are not quantified as monetized economic values does not mean that they were not considered in the context of the analysis. Second, the findings of the ECONorthwest report that the benefits outweigh the costs of breaching the dams rely on the implicit assumption that breaching would result in restoration of salmon populations. The fish effects analysis in Section 3.5 of the EIS does not find that MO3 would result in recovery of salmon or steelhead populations or in restoring the populations to historical levels. Thus, the values presented in the ECONorthwest report should not be considered as representative of the benefits of MO3. However, the results from the ECONorthwest study contribute to the overarching conclusion of Section 3.15.2.2 that describes that the literature consistently demonstrates that people hold passive use values for salmon. Additionally, it is important to note that this EIS has undergone a third party neutral Independent Expert Peer Review on the tools used (including the economic models), as well as the assumptions and conclusions in the EIS.
6299	39	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	B. The Lead Agencies process for developing the economic analyses failed to adequately involve all interested parties. The DREW, described above, also developed collaborative economic studies for the Corps evaluation of potential impacts from removing the Snake River Dams. These studies were more comprehensive than those included in the DEIS. For the same reasons discussed above, the Lead Agencies should have organized a workgroup comparable to the DREW to produce an economic analysis for the DEIS rather than relying on the flawed cooperating agency process. The remainder of this section describes flaws in the Lead Agencies economic analyses and provides recommendations for additional analyses in the FEIS. As above, the Yakama Nation recommends that the Lead Agencies convene a collaborative workgroup to address these flaws and develop the necessary economic analyses. 211 These studies are described in pg. 61 to 64, infra. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 57	It is important to note that the EIS has undergone a third party neutral Independent Expert Peer Review on the tools used (including the economic models), as well as the assumptions and conclusions in the EIS. The four lower Snake River dams are cost effective. Hydropower benefits exceed costs by $209M to $513M annually. The average annual costs to operate and maintain the four lower Snake River projects is $75M (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32M (Appendix Q, Table 4-1). The annual hydropower (Table 3-171) and navigation (Table 3-244 & Table 3-246) benefits alone for these projects are estimated at $284M to $588M in the base case analysis for MO3. These hydropower values include the effect of other measures in MO3, but the majority of this value stems from generation at the four lower Snake River dams. This estimate is derived from what the hydropower analysis called the base case and does not account for the full characteristics of the lower Snake River projects generation such as sustained peaking capability and fast ramping ability to integrate variable renewable energy sources. Fully replacing the generation capabilities of the four lower Snake River dams could roughly double estimated replacement resource costs (see Section 3.7.3.5). As explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, breaching the four lower Snake River dams would have a direct and substantial impact on the supply of Federal power to meet regional load requirements. These impacts would impact both actual energy to meet regional load requirements and generating capacity (peaking capacity) to meet variability in loads. The four lower Snake River dams are among the most valuable projects in FCRPS. These dams provide over 1,000 MW of carbon-free energy and up to 2,000 MW of peaking capacity at certain times of the year. The dams also have unparalleled ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,200 MW of capability in certain months of the year. While the increase in solar and wind generation is consistent with the EIS discussion in 3.7.2.1 Power Generation, the EIS still finds that the regional power system requires replacement power resources to maintain reliability under MO3. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review (see Footnote 1 below), the Headwater/Lower Snake Asset Class (see Footnote 2 below) is forecast to have a 50-year levelized cost of generation (see Footnote 3 below) of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. Footnotes: 1. The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2. In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					3. Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
6299	40	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	C. The Lead Agencies should have analyzed the unique economic impacts of the CRS on the Yakama Nation and its members. The CRS transformed major portions of the Columbia and Snake Rivers and severely damaged the ability to provide sustainable populations of fish and wildlife. The construction and operation of the dams took substantial Treaty-protected wealth away from the Yakama Nation and other Native Nations. As part of the DREW, CRITFC developed a detailed analysis, titled Tribal Circumstances and Impacts of the Lower Snake River Project on the Nez Perce, Yakama, Umatilla, Warm Springs and Shoshone Bannock Tribes (1999 Tribal Circumstances Report), on how the construction and operation of federal dams on the Snake River affected Native Nations.212 Per the CRITFC report, the construction and operation of the CRS has devasted salmon runs. Those salmon runs were essential to the economy, culture, and religion of the Yakama Nation. The 1999 Tribal Circumstances Report delivers a candid and data-driven perspective on the less than apparent economic and social impacts of the CRS on Tribal communities. It tied multiple expressions of Tribal values to an understanding of Tribal well-being measured by several different economic indicators. These economic indicators were framed in terms of a hierarchy of needs.213 The 1999 Tribal Circumstances Report also observed linkages between the availability of traditional foods, particularly salmon, and Tribal health as measured by mortality rates associated with a loss of nutritional foods. It described the importance of salmon to Tribal members cultural and traditional well-being, sense of belonging, and self-esteem.214 It also used Tribal poverty, Tribal unemployment, Tribal per capita income, Tribal health and Tribal assets as more traditional indicators of Tribal well-being, providing relevant data for each indicator. Ultimately, the 1999 Tribal Circumstances Report concluded that the effect of the Snake River dams on the productivity of the Snake River Basins salmon and steelhead had caused significant and adverse impacts to Tribal well-being, both economically and otherwise. The 1999 Tribal Circumstances Report provides a useful framework for considering Tribal concerns and perspectives with respect to unique economic impacts of the CRS. For that reason, the Yakama Nation called for the incorporation the 1999 Tribal Circumstances Report analysis into the DEIS economic and environmental justice analyses, updated as appropriate based on new information.215 The Lead Agencies failed to do so, or the manner in which the analysis has been incorporated or considered is not transparent. 212 This analysis is included as Appendix D to these comments. 213 These needs underlie human kinds goal for an increasing trend toward unity, integration, or synergy, within the person. For instance, someone who is absorbed totally in fulfilling ongoing hunger needs will attend less to safety needs; and, a person whose security is constantly threatened will be less able to develop intimacy with others. See CRITFC, TRIBAL CIRCUMSTANCES AND IMPACTS OF THE LOWER SNAKE RIVER PROJECT ON THE NEZ PERCE, YAKAMA, UMATILLA, WARM SPRINGS AND SHOSHONE BANNOCK TRIBES (1999) (1999 Tribal Circumstances Report) at 46. 214 Id. at 45. 215 The Yakama Nation made this request during the cooperating agency process. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 58 The Tribal Perspectives Report, prepared by the Treaty Tribes and included in Appendix P of the DEIS, draws heavily from the 1999 Tribal Circumstances Report while also supplementing it with new information and analyses. For example, the Tribal Perspectives Report compares the Tribal poverty levels and income information from the 1999 Tribal Circumstances Report with current data.216 The current data aligns with that of the 1999 Tribal Circumstances Report: poverty rates for members of the Treaty Tribes are still two to three times the national average, while their per capita income is less than half the national average. The tables included as Figures 8 and 9 below illustrates these statistics.217 Figure 8 216 TRIBAL PERSPECTIVES REPORT, supra, at 9. 217 Id. 0.00% 5.00% 10.00% 15.00% 20.00% 25.00% 30.00% 35.00% 40.00% 45.00% U.S. (All) YN (AIANa) CTUIR (AIANa) NPT (AIANa) CTWSRO (AIANa) Poverty Rate 1990-95 2012-16 Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 59 Figure 9 The Treaty Tribes did not have the resources available to perform a contemporary analysis of its members unemployment and death rates for the Tribal Perspectives Report. However, the 1999 Tribal Circumstances Report found that unemployment for the Native Nations studied was between three and thirteen times higher than for the regions nonIndian populations.218 The rate of death for the Yakama Nation was twice the non-Tribal rate in Washington.219 The chart below, included as Figure 10, illustrates these numbers. Figure 10 If the Treaty Tribes had been able to conduct these studies today, it is likely that they would have reached similar conclusions. The reasons for the irregularly high levels of poverty, unemployment, and death rates and low levels of income are the same today as in 1999: the absence of salmon, steelhead, and other traditional foods. Tribal members often prefer fishing-related means of economic support that preserve and perpetuate cultural values. As the 1999 Tribal Circumstances Report and the Tribal Perspectives Report concluded, negative economic measurements in Tribal communities rise steeply where Tribal members are unable to harvest salmon and steelhead due to depleted runs and degraded habitats. 218 1999 Tribal Circumstances Report, supra, at 1. 219 Id. $0 $5,000 $10,000 $15,000 $20,000 $25,000 $30,000 $35,000 U.S. (All) YN (AIANa) CTUIR (AIANa) NPT (AIANa) CTWSRO (AIANa) Per Capita Income 1990-95 2012-2016 Tribal Circumstances for Columbia River Treaty Tribes (1999) Idaho Oregon Wash Families in Poverty 29% 43% 27% 32% 10% 12% 11% Unemployment 20% 23% 20% 19% 6% 6% 6% In winter 62% 73% 21% 45% Ratio of Tribal to non-tribal death rate 1.7 1.9 1.2 1.6 Indicators of Wellbeing Non-Tribal DataNez Perce Yakama Umatilla Warm Springs Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 60 It is impossible to ascertain the true economic effect of the CRS or the Preferred Alternative without considering these impacts. Accordingly, the data and analysis included in both the 1999 Tribal Circumstances Report and the Tribal Perspectives Report (updated as necessary) are critical to an adequate economic analysis of the FEIS.	The EIS recognizes the importance of salmon to Tribes in a number of Sections throughout the document. The Fisheries Section 3.15 as well as Section 3.17, in particular, include discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries Section 3.15.2.1, which includes sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries. The co-lead agencies also considered the information in the Tribal Perspectives that were submitted by several tribes during the drafting and evaluation of the EIS. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
6299	41	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	D. The Lead Agencies economic analyses fail to consider the disparity in wealth benefits and drawbacks from the CRS. The CRS transformed the production functions of the impounded portions of the Columbia and Snake Rivers, taking substantial Treaty-protected wealth away from the Yakama Nation and other Native Nations. As described above, this has indirectly led to extreme poverty, low-income, unemployment, and death rates in Tribal communities. At the same time, the CRS substantially increased the wealth of non-Indians through enhanced production of electricity, agricultural products, transportation services, flood control, and other associated economic benefits. Yakama Nation members have not shared in this increased wealth on a commensurate basis. Therefore, the negative economic impacts of the CRS fell disproportionately on the Yakama Nation. Furthermore, the potential negative economic effects on non-Tribal electricity customers contemplated in the DEIS alternatives are insignificant compared to the effects on Tribal communities described in the 1999 Tribal Circumstances Report and the Tribal Perspectives Report. For example, average retail rates will increase by 1.6% to 3.6% under MO3.220 MO4 would create upward pressure on retail electricity rates that would on average, account for 1.737% to 1.742% of household income. However, [t]his represents only a 0.18% to 0.31% increase in the percent of income spent on electricity relative to the No Action Alternative.221 These slight increases in cost do not compare with the significant economic impact caused by the loss of fishing opportunity described in the previous section. The disparity in wealth benefits, coupled with the disproportionate negative impacts, delineates a significant environmental injustice which the Lead Agencies have not adequately addressed in the impact analyses. Consistent with Executive Order 12898 and related federal guidance, the Lead Agencies must clearly identify and address this disparity in the FEIS. Specifically, the Lead Agencies must identify which alternatives would perpetuate the wealth inequality by failing to adequately protect fish populations (or otherwise not diminishing the economic burden on Tribal communities). The Preferred Alternative does not provide any significant benefits to salmon runs (see above) and will therefore continue these disparities. In addition to other corrections, the FEIS must identify mitigation measures adequate to minimize or rectify the disparity.	he EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The EIS recognizes the importance of salmon to Tribes in a number of Sections throughout the document. The Fisheries Section 3.15 as well as Section 3.17, in particular, include discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries Section 3.15.2.1, which includes sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries. The co-lead agencies also considered the information in the Tribal Perspectives that were submitted by several tribes during the drafting and evaluation of the EIS. Additional information has also been added to the Environmental Justice Section 3.18 to more clearly articulate the affects on Tribes.
6299	42	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	E. The Lead Agencies regional economic analyses overstate the likely economic impacts of MO3 and MO4. These comments previously describe why the Lead Agencies analysis of MO3 and MO4 represents a high-end estimate of power costs and rate impacts. Likewise, the Lead Agencies exaggerate the overall economic impacts of MO3 and MO4 by failing to provide 220 DEIS at 3-927. 221 DEIS at 3-955. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 61 appropriate context for these impacts. This exaggeration undermines the reliability of the impact analysis that informs the selection of a Preferred Alternative. The Lead Agencies conclude that MO3 and MO4 will respectively result in the loss of 4,900 and 4,000 jobs. The 2018 total employment in Washington, Idaho, Montana, and Oregon was 6,314,600 jobs.222 Therefore, the project job losses reported for MO3 and MO4 respectively represent 0.08% and 0.06% of the total employment. The projected job loss for the Preferred Alternative represents 0.002% of the total employment. The Lead Agencies also fail to put the economic output effects in the context of the total regional economy. The 2018 regional output for Washington, Idaho, Montana, and Oregon totaled $932,992,000,000.223 The projected loss of economic output for MO3 and MO4 respectively constitute only 0.08% and 0.07% of the total regional output. The projected loss of economic output for the Preferred Alternative constitutes 0.0021% of the total regional output. The impacts on regional jobs and economic output noted by the Lead Agencies for MO3 and MO4 amount to less than eight one-hundredths of a percent. This is insignificant compared to the damages to Tribal economies resulting from the CRS, as discussed above. The Lead Agencies should include a more detailed analysis of the regional economy in the FEIS that considers the effects of each alternative in the broader regional context. Relatedly, the Lead Agencies calculate a net present value (NPV) impact for each alternative without any context of the total regional NPV. Without this context, the Lead Agencies calculations are meaningless in terms of the	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. Regarding the costs of replacing power, the EIS describes the replacement resources that would be needed to maintain regional reliability at the No Action Alternative (No Action Alternative) levels based on two potential portfolios: one based on renewable resources and another based on natural gas resources, which are generally the least cost means to maintain reliability (Section 3.7.3.5, Potential Replacement Resources and Associated Costs). The EIS uses the best available resource cost information from the Northwest Power and Conservation Council to estimate the potential range in costs of these replacement resources. In addition, the changes in commercial and industrial effects (jobs and income) were estimated based on the increased electricity costs to households and businesses under MO3. Under MO3, employment is anticipated to decrease between 2,100 and 3,500 jobs compared to the No Action Alternative. As the commenter indicates, this change in jobs is a very small portion of the total jobs in Washington and Oregon. However, reduced hydropower reduction under MO3 would result in an average annual economic cost of $150 million (replacement cost at market price of foregone power) and the estimated increase in the marginal cost of producing power to meet demand based on additional average annual fixed and variable costs is estimated to range from $270 million to $540 million. In Section 3.7, Power and Transmission, Bonneville conducted a financial analysis, including a net present value (NPV) calculation, that assesses alternatives financial value given the likely changes in power generation and anticipated future cash flows. This evaluation is not indicative of the social welfare or regional economic effects. In addition, MO3 would result in short-term beneficial effects to regional economic conditions (jobs and income) associated with construction of the structural measures, including dam breaching activities at the four lower Snake River projects (See Section 3.19.3 and Annex C of Appendix Q). Other resources would experience beneficial and adverse effects compared to the No Action Alternative under MO3, which are described in the applicable resource section. For example, adverse regional economic effects to recreation and visitor spending in the short-term under MO3 would occur with the elimination of reservoir recreation at the lower Snake River projects, while river recreation in the long-term is likely to be reestablished, at least partially offsetting the adverse effects in the short-term.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				comparisons of impacts from various alternatives or measures included in them. The Lead Agencies should provide the total regional NPV in the FEIS to clarify the impact of each alternatives NPV.	
6299	43	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	F. The Lead Agencies employment analyses fail to consider the jobs and economic benefits that each alternative would create. In the power analysis, the Lead Agencies describe in some detail the number of resources that would need to be constructed to replace the power reductions associated with MO3 and MO4.224 However, the Lead Agencies analysis of employment impacts does not appear to include the jobs that would be created by constructing these resources and mitigating effects. A 1999 study by ECONorthwest developed for the DREW found that removal of the Snake River dams would create 23,280 to 25,088 construction jobs.225 The table below, included as Figure 11, lists the specific types of potential jobs. 222 2018 State Occupational Employment and Wage Estimates BUREAU OF LABOR statistics, (www.bls.gov/oes/2018/may/oessrcst.htm) (last accessed April 13, 2020). 223 BUREAU OF ECONOMIC ANALYSIS (https://apps.bea.gov/itable/iTable.cfm?ReqID=70&step=1#reqid=70&step=1&isuri=1) (last accessed April 13, 2020). The 2018 information was readily accessible; the Action Agencies should be able to develop more recent data. 224 DEIS at 3-904, 3-940. 225 ECONORTHWEST, Presentation to CRITFC (1999). Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 62 Figure 11 In the same study, ECONorthwest also concluded that Snake River dam removal would create 473 long-term jobs, primarily in recreation. The table below, included as Figure 12, lists the specific types of potential long-term jobs. Figure 12 An analysis of the potential jobs created by an alternative is essential to understanding the potential impact of jobs lost. Based on the 1999 ECONorthwest study, it is likely that the projected job loss numbers discussed above will be even more insignificant once considered alongside the potential number of jobs created. The Lead Agencies also failed to consider the overall economic benefits that each alternative would create. A 2019 ECONorthwest study analyzed the full range of benefits and costs associated with the removal of the Snake River dam and found, for example, that recreational values alone could generate between $557,000,000 and $1,600,000,000.226 The net economic increase was $505,000,000 in output, with $492,000,000 of value added in labor income and an increase of 317 average annual job years.227 Energy Vision for the Columbia River identifies actions that could help protect salmon populations while also saving electricity customers $1,300,000,000 per year. This benefit is approximately double the Lead Agencies estimations for the economic costs of MO3 and MO4. 226 ECONORTHWEST, LOWER SNAKE RIVER DAMS ECONOMIC TRADEOFFS OF REMOVAL (2019), at 130. 227 Id. at vii, 130. Construction Jobs Low High Modifying dams 11,768 11,768 Power Plant construction 7,250 7,250 Highway and railroad 2,554 4,362 Well Modifications 1,175 1,175 Water pump modifications 292 292 Transmission lines 241 241 Total 23,280 25,088 Long-term jobs New recreation 3,126 Power plan ops 1,100 grain transport 475 agriculture (part time) (2,256) dam ops (1,193) exist rec (779) Net 473 Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 63 The FEIS must reconcile the Lead Agencies economic analysis with should the kind of analysis of the jobs and economic benefits that each alternate could create similar to those done by ECONorthwest. At a minimum, this analysis should include a range forecast of the net costs and economic impacts.	There are benefits and costs associated with operating the lower Snake River projects. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. This is consistent with NEPA guidance, which describes that the EIS should not be a cost-benefit analysis if there are important tradeoffs that are not quantified. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The ECONorthwest analysis and the EIS employ different analytical frameworks and rely on different findings with respect to the outcomes of breaching the four lower Snake River dams. The study used a very limited sample of 20 trips to the region. First, the ECONorthwest report applies a cost-benefit analysis framework, emphasizing monetization of all categories of impacts. Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on fish are not quantified as monetized economic values does not mean that they were not considered in the context of the analysis. Second, the findings of the ECONorthwest report that the benefits outweigh the costs of breaching the dams rely on the implicit assumption that breaching would result in restoration of salmon populations. The fish effects analysis in Section 3.5 of the EIS does not find that Multiple Objective alternative 3 would result in recovery of salmon or steelhead populations or in restoring the populations to historical levels. Thus, the values presented in the ECONorthwest report should not be considered as representative of the benefits of MO3. However, the results from the ECONorthwest study contribute to the overarching conclusion of Section 3.15.2.2 that describes that the literature consistently demonstrates that people hold passive use values for salmon.
6299	44	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	G. The Lead Agencies NPV analyses fail to include federal discount rates. The Lead Agencies economic analysis calculated the NPV of each alternative using a 7.9% discount rate over a thirty-year time period. However, the 2018 federal water resources planning rate provides for a 2.75% discount rate. This rate, which should at least apply to the Bureau of Reclamation (if not all of the Lead Agencies), would significantly reduce the NPV impacts described in the DEIS. The Lead Agencies must explain why they did not use federal water resources planning rate in the DEIS. If this rate applies, then the Lead Agencies should adjust the NPV impacts calculations in the DEIS accordingly.	Monetized values throughout the EIS are presented in fiscal year 2019 dollars. In general, present values, or annual equivalent values are estimated utilizing the 2019 Federal water resource planning rate of 2.875. Bonneville completed a financial analysis of alternatives separately from the economic analysis, which does utilize the official agency risk-adjusted discount rate of 7.9%. However, as shown under the Social and Economic Effects of Changes in Power and Transmission Section (under Section 3.7.3), the net present value of social welfare effects of hydropower generation are calculated based upon the 2019 Federal water resource planning discount rate.
6299	45	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	H. The Lead Agencies economic analyses do not incorporate non-use values. The total economic value that an individual derives from a natural resource, such as a resource basin, can be conceptually divided into use and non-use values. Use values represent tangible features of a commodity that satisfy an individuals want or need. Nonuse values, on the other hand, capture an individuals preferences for public goods or resources that are not derived directed from use. For example, non-use values might include the value of improvements to a river basin for an individual who never visits the river basin, consumes fish from the river basin, or otherwise uses resources from the river basin. Factors that may give rise to non-use values include a desire to preserve the functioning of specific ecosystems; a desire to preserve ecosystems to maintain the option for future use; and a feeling of environmental responsibility or altruism towards plants and wildlife. The 1999 Corps EIS evaluating the removal of the Snake River dams discussed throughout these comments included an extensive analysis on non-use values.228 That analysis concluded that the non-use values of Snake River dam removal ranged from $220,000,000 to $1,000,000,000.229 The table below, included as Figure 13, lists values for all the use and non-use values from the 1999 evaluation EIS and illustrates the potential significance of non-use values. 228 JOHN LOOMIS, RECREATION AND PASSIVE USE VALUES FROM REMOVING THE DAMS ON THE LOWER SNAKE RIVER TO INCREASE SALMON (March 1999). 229 Id. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 64 Figure 13 Factoring in non-use values, the net impacts of Snake River dam removal were a cost of $59,000,000 dollars in the low case to a benefit of $664,000,000 in the high case.230 A 2019 ECONorthwest study concluded that the NPV for Snake River dam removal totaled $10,970,000,000.231 By analyzing new costs, reduced costs, and public benefits that include non-use values, the study found an NPV benefit of $8,650,000,000.232 The Department of the Interior commissioned a study of non-use values for removing four dams on the Klamath River in 2012. That analysis used a conservative methodology for determining the non-use value associated with Klamath dam removal and restoration of Klamath Basin resources.233 Despite the conservative approach, the study identified $2,158,000,000 in potential non-use benefits for Oregon and California and $15,645,000,000 in potential non-use benefits nationwide.234 Clearly, non-use values have been recognized by economists as potentially amounting to serious economic benefits. Indeed, the non-use values described in the 2019 ECONorthwest study are greater than many of the costs that the Lead Agencies have identified for MO3 and MO4. Nevertheless, the Lead Agencies economic analysis does not contemplate new costs, reduced costs, and public benefits that include non-use values. This is inadequate. The Lead Agencies have authority to conduct non-use value studies for the CRSO EIS. 230 This calculation represents the numbers included in the Corps public EIS for the evaluation. The analysis conducted by the private consultant showed a range of benefits from $386,000,000 to $3,000,000,000. 231 LOWER SNAKE RIVER DAMS ECONOMIC TRADEOFFS OF REMOVAL, supra, at iv. 232 Id. The 2019 ECONorthwest report also details new costs and reduced costs for grid services, dam removal, irrigation, transportation, and recreation. Id. The Lead Agencies should include a similar analysis in the FEIS. 233 DEPT. OF INTERIOR, SECRETARIAL DETERMINATION FINDINGS OF TECHNICAL STUDIES (2017) at 156. 234 Id. Impacts of Snake River Dam Removal Annual Impacts (millions of dollars) Corps to Public Econ Appen. Ranges Sector Low High Low High Electricity supply $ (250) $ (300) $ (241) $ (291) Recreation-net 65 $ 70 $ 44 $ 364 $ Transportation $ (35) $ (40) $ (35) $ (40) Irrigation & water supply $ (14) $ (17) $ (2) $ (17) Commercial Fishing $ 1 $ 1 $ 1 $ 1 ImpImentation costs $ (46) $ (50) $ (21) 21 $ Total $ (279) $ (336) $ (254) 38 $ Passive values 220$ 1,000 $ 640$ $ 2,977 Net Impacts $ (59) 664 $ 386$ $ 3,015 Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 65 Therefore, the Lead Agencies should include such a study in the FEIS. This will provide a more accurate picture of the economic impact of MO3 and MO4.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. The EIS does not employ a cost-benefit framework for decision-making. This is consistent with NEPA guidance, which describes that the EIS should not be a cost-benefit analysis if there are important tradeoffs that are not quantified. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. A summary table in Section 7.4 has been added to provide a concise description of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a number of resources. The Vulcan Report employs a cost-benefit framework. Consequently, a focus solely on the monetized economic costs and benefits would exclude important tradeoffs associated with the alternatives communicated in the EIS, including effects on fish. Regarding passive-use values, Section 3.15.2.2 of the EIS describes the recent ECONorthwest study, highlighting the objective and approach to estimating willingness-to-pay for salmon restoration. The ECONorthwest analysis and the EIS employ different analytical frameworks and rely on different findings with respect to the outcomes of breaching the four lower Snake River dams. First, the ECONorthwest report applies a cost-benefit analysis framework, emphasizing monetization of all categories of impacts. Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on fish are not quantified as monetized economic values does not mean that they were not considered in the context of the analysis. Second, the findings of the ECONorthwest report that the benefits outweigh the costs of breaching the dams rely on the implicit assumption that breaching would result in restoration of salmon populations. The fish effects analysis in Section 3.5 of the EIS does not find that Multiple Objective alternative 3 would result in recovery of salmon or steelhead populations or in restoring the populations to historical levels. Thus, the values presented in the ECONorthwest report should not be considered as representative of the benefits of MO3. However, the results from the ECONorthwest study contribute to the overarching conclusion of Section 3.15.2.2 that describes that the literature consistently demonstrates that people hold passive use values for salmon.
6299	46	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	5.5. The Lead Agencies climate change analyses fail to consider important effects and driving factors of climate change. This section describes flaws in the Lead Agencies climate change analyses.235 As a general comment, the Yakama Nation reiterates its recommendation that the Lead Agencies incorporate Energy Vision for the Columbia River and the other power analysis studies described above. These studies include a number of proposals on energy and renewable resource actions that are pertinent to the Lead Agencies climate change analysis. A. The Lead Agencies climate change analyses fail to properly analyze the impacts of sediment changes. In Chapter 4.2.2 of the DEIS, the Lead Agencies discuss the influence of climate change on river mechanics, including sediment transportation and deposition.236 Section 4.2.2.4 describes sediment changes in Region D McNary, John Day, The Dalles, and Bonneville Dams under MO3.237 However, the Lead Agencies fail to evaluate what impact these changes would have on affected resources. Therefore, it is unclear whether the [i]ncreased sediment transport and localized suspended sediment concentrations that the Lead Agencies project would result from MO3 will result in beneficial or adverse impacts. Restoring key riverine ecological functions and processes, such as natural sediment flow, to natural levels can improve habitat for fish and wildlife is desirable for salmonid production.238 On the other hand, excessive sediment levels can have damaging impacts of all life stages of fish, particularly salmonids.239 The Lead Agencies must include an impact analysis here to properly evaluate the influence of climate change on river mechanics. Where impacts are found, the Lead Agencies must develop measures to mitigation impacts caused by excessive sediment levels. B. The Lead Agencies climate change analyses fail to properly analyze the longterm effects of changes in water quality and temperature. In the introduction of Section 4.2.3 of the DEIS, the Lead Agencies acknowledge the likelihood of long-term water temperature increases in the Columbia River Basin.240 235 The Lead Agencies appear to have mislabeled several subsections here (anadromous fish, FRM, navigation and transportation, recreation, visual, noise, etc.). For clarity, the Lead Agencies should correct these errors in the FEIS. 236 DEIS at 4-24. 237 DEIS at 4-27. 238 COUNCIL, RETURN TO THE RIVER (2000) at 34. 239 SALMON & TROUT CONSERVATION, THE IMPACT OF EXCESS FINE SEDIMENT ON INVERTEBRATES AND FISH IN RIVERINE SYSTEMS (2017) at 4. 240 DEIS at 4-27. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 66 However, in several analyses of each region and alternative, the Lead Agencies fail to even mention	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). Other resources were evaluated to the extent the data and available science would allow. Appendices I and J provide supporting information for the statements made regarding hydropower.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				water temperature changes at all.241 Where the Lead Agencies do discuss water temperature, the analyses frequently focus more on the immediate temperature impacts of each alternative and do not include any long-term projections. For example, in considering MO3 for Region C, the Lead Agencies only discuss temperature changes caused by seasonal and daily variability.242 The Lead Agencies should comprehensively analyze the long-term projections for water temperature under MO3s return to more normative river conditions. This analysis must include an evaluation of impacts to resources caused by these temperature changes. C. The Lead Agencies climate change analyses fail to analyze the effects on anadromous fish. The Lead Agencies have not adequately described potential effects of climate change on anadromous fish, despite the availability of extensive studies on the impact of climate change driven temperature and water quality changes on these species. For example, meaningful analyses of climate change impacts require a presentation of the relationship between riverine and reservoir water temperatures over time and the thresholds for sublethal and lethal effects on anadromous fish. Water temperatures within the CRS already can reach levels lethal to anadromous fish during some summer months. More robust analyses on the effects of temperature changes is a critical component of identifying measures to be included in a Preferred Alternative. Throughout the climate change analysis of effects on anadromous fish, the Lead Agencies make vague and conclusory statements about what could or may occur with respect to climate change impacts, but do not offer any further information or data regarding the likelihood of these occurrences. For example, [i]ncreased transportation of juveniles may benefit some adult returns to Bonneville Dam, but could also increase the incidence of fallback and straying of adult salmonids;243 [a]dult migration under MO2 may be improved by lower spill, but the overall warming of the river water could offset this effect and result in poorer upstream migration and adult survival;244 [s]ummer foraging for green sturgeon could be decreased further with climate change;245 and [f]orage habitat for green sturgeon could be decreased or disrupted by lower summer flows and flow fluctuations in July and August, and this could be enhanced by climate change effects.246 The Lead Agencies should explain with more specificity the likelihood that these impacts and effects will occur. Furthermore, the Lead Agencies how, they reached the the conclusions [they] have drawn from [their] chosen methodology [with regard to climate change impacts on anadromous fish,] and the reasons [they] considered the underlying evidence to be reliable. 241 DEIS at 4-29 (analysis of MO4 effects on Region A); 4-30 (analysis of MO1 effects on Region B); 4-312 (analyses of MO2 and MO4 effects on Region C). 242 DEIS at 4-31. 243 DEIS at 4-37 (emphasis added). 244 Id. 245 DEIS at 4-38 (emphasis added). 246 DEIS at 4-39 (emphasis added). Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 67 The Lead Agencies rightfully state that, with respect to MO3, Fall Chinook salmon habitat increases and increases in juvenile salmon and steelhead survival, decreases in travel time, and reductions in powerhouse encounters in MO3 could be reduced or offset by the effects of climate change.247 However, the Lead Agencies analysis for the No Action Alternative, MO1, and MO2 (along with the Preferred Alternative) do not clearly indicate that climate change will further exacerbate these alternatives adverse impacts to salmon because those alternatives do not increase survival rates and habitat or decrease travel times and powerhouse encounters. In light of climate change effects, these alternatives will result in even worse outcomes for anadromous fish. D. The Lead Agencies climate change analyses do not adequately consider impacts to power generation. The Lead Agencies assert that climate change is not likely to change the general conclusions from the power analysis of the relative effect of one MO versus another but do not substantiate this claim with any facts or analyses. Moreover, as noted above, the Lead Agencies power analysis contains a number of flaws. Without correcting these flaws, the Lead Agencies cannot properly conclude that climate change will not impact the power analysis. The Lead Agencies should correct the power analysis consistent with the recommendations discussed above and then disclose how climate change effects will change under each alternative. For example, these comments previously describe problems caused for the Northwest power system caused by climate change when a 2018 heat wave affected the Pacific Coast, Nevada, and Arizona. The heat wave increased the demand for electricity to meet air conditioning loads; constraints in natural gas supplies for electricity generating plants in southern California increased prices; wildfires reportedly threatened transmission lines. The results increased market prices from $16.65 per megawatt hour in June, to $71.88 per megawatt hour in July, and $69.96 per megawatt hour in August.248 These events are likely to increase in the coming years due to climate change, intensifying the risk of more price spikes. These issues should be addressed in the FEIS. E. The Lead Agencies climate change analyses fail to clarify the alternatives impacts to recreational fishing. The Lead Agencies analysis of climate change impacts on recreation does not make clear that the No Action Alternative, MO1, or MO2 would not increase recreational salmon fishing in any region. Likewise, it does not make clear that MO3 would increase recreational salmon fishing. The Lead Agencies must clarify these points and account for them in the analysis of climate change impacts on recreation. F. The Lead Agencies climate change analyses fail to provide an individualized assessment of the impacts to fisheries under each alternative. 247 DEIS at 4-38. 248 Information from the week ending September 29, 2018. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 68 The Lead Agencies do not provide an analysis for climate change impacts on fisheries specific to each alternative. Instead, the Lead Agencies arbitrarily lump all of the alternatives together and conclude that climate change will result in adverse impacts to fisheries under every alternative. An individualized assessment of the likely climate change impacts under each alternative is necessary for hard look purposes. Notably, this conclusion does not appear to affect the Lead Agencies the biological analysis, which shows no measurable benefits for upper Columbia or Mid-Columbia anadromous fish for any alternatives and no measurable benefits on Snake River anadromous fish for the No Action Alternative, MO1, MO2, or the Preferred Alternative.	
6299	47	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	A. The Lead Agencies analyses of the Preferred Alternatives Flex Spill operation measure include biases and unproven assumptions. The Preferred Alternative Flex Spill operation relies on hourly changes in operations.249 However, all of the Lead Agencies analytical models reflect daily average operations. Therefore, the benefits of the fish analyses are biased toward showing benefits to fish populations, since a daily average of sixteen hours of high spill and eight hours of performance spill will tilt the analysis towards the higher spill. The Lead Agencies must update their analytical models in the FEIS to align with the planned Flex Spill measures so that the relevant analyses are accurate. Moreover, the Preferred Alternative Flex Spill operation relies on the theoretical assumption that reducing the number of powerhouse encounters for fish will reduce latent mortality experienced through ocean migration as has been noted earlier. The majority of fish benefits in the Preferred Alternative depend on this unproven theory. The Lead Agencies must explain why they consider the latent mortality theory to be reliable. The Preferred Alternative does not provide adequate mitigation if the Lead Agencies assumption regarding latent mortality turns out to be false. B. The Lead Agencies Preferred Alternatives Flex Spill operation measure does not offer a long-term plan for protection of fish populations. The Preferred Alternative Flex Spill operation is only planned for the first year.250 After that, the Lead Agencies will employ an undefined adaptive management process for determining flex spill operations.251 The rational basis for this approach has not been set out. A more protective and stable approach would be to adopt a Preferred Alternative Flex Spill operation with a fifteen-year plan (consistent with the BA). This plan should feature an adaptive management process that actively engages the Yakama Nation to assure consistency of changes with treaty rights and tribal cultural resources values before 249 Memorandum from Brandon Chockley and Jerry McCann to Michele DeHart (FPC), Subject: Preferred Alternative Modeling (January 13, 2020). 250 DEIS at 7-33; BA at 2-58. 251 Id. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 69 deviations from the fixed operation occur. This type of meaningful engagement would conform to the Lead Agencies trust responsibility to the Yakama Nation.	In its analysis of effects, the Draft EIS used current high quality information, including models and studies published in peer review science journals. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill operations on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts on juvenile migrants. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. Regarding biases due to hourly vs.. daily averages: In practice, model estimates may not overestimate PITPH due to day vs. night passage differences because limitations on nighttime spill reductions are already in place through the adaptive management process and lessons learned from the 2019 flexible spill operation. These adjustments in the amount of night time spill were informed by state, Tribal, and Federal biologists with expertise in dam operations and their effects to fish passage. These examples of adaptive management will continue during post-ROD operations. The statement that the flex spill operation is only planned for one year is not an accurate interpretation of the Preferred Alternative. If no adaptive management needs are identified, the operation would continue until modified by the co-lead agencies.
6299	48	brendan@yakamanation-olc.org	Confederated Tribes and Bands of the Yakama Nation	5.7. The Lead Agencies analyses of proposed mitigation measures do not clearly explain the extent or benefits of the measures. This section describes flaws in the Lead Agencies approach to mitigation measures. A. The Lead Agencies fail to transparently describe the extent of existing mitigation programs. The Lead Agencies descriptions of mitigation programs in the Preferred Alternative do not acknowledge that many of the programs relied on for mitigation have been diminished or have not actually been carried forward since the initiation of the EIS development process. Similarly, the Lead Agencies do not state the anticipated level of funding for existing mitigation programs under the Preferred Alternative relative to the No Action Alternative. The BPA-funded fish and wildlife program has been reduced by $20,000,000 in 2018 relative to 2016.252 The Corps has operated its Columbia River Fish Mitigation program at very low levels for several years. To some extent, the Corps has asserted that no additional major actions are necessary. In addition, the Corps has also shifted its predator management programs to routine operation and maintenance funding. Therefore, the Preferred Alternative relies on mitigation programs that are currently reduced or funded at lower levels than described in the fully funded No Action Alternative. The Lead Agencies should be aware of changes to their own mitigation problems. If these changes are not accounted for in the mitigation analyses, then the analyses are not based on the evidence before the Lead Agencies and are effectively meaningless. The Preferred Alternative included in the FEIS must accurately account for the cost of mitigation program implementation and the means of assuring the necessary funding. Similarly, the Lead Agencies do not state the anticipated level of funding for existing mitigation programs under the draft Preferred Alternative relative to the No Action Alternative. Accordingly, it is impossible to evaluate the potential biological benefit of proposed mitigation programs. A reader must infer the size and scale of mitigation programs based on the measures presented in the BA and assume that current fiscal year 2020 funding levels will persist to support these measures. The necessity for such inference and assumption are contrary to NEPAs purpose of environmental impact identification and disclosure. B. The Lead Agencies fail to justify the benefits expected from significant proposed mitigation measures. The Yakama Nation is unclear how	Ongoing mitigation programs are summarized in Chapters 2, 5, and 7. Because these ongoing programs are part of the No Action Alternative and carried into the Multiple Objective alternative and the Preferred Alternative, these ongoing programs are analyzed for each resource for each alternative as part of that alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. Regarding Northwest Power Act compliance, the comment asserts inadequate analysis in the EIS as to the efficacy or benefits of mitigation funded through Bonneville's Fish and Wildlife Program. Bonneville's Fish and Wildlife Program is first described in section 2.4.2 as an existing program under the No Action Alternative that will continue. This section provides a high-level overview of Bonneville's Fish and Wildlife Program, many of its major subprograms and their benefits, including habitat actions, hatchery actions, predator management, lamprey research and mitigation, and wildlife mitigation. Section 2.4.2 also describes some of the many CRS improvements and the associated benefits for fish. In addition to this overview of Bonneville's Fish and Wildlife Program, the description of the affected environment throughout the relevant sections in Chapter 3 of the EIS, by definition, reflects the effects of past and ongoing mitigation efforts, even if they are not itemized or highlighted as being the results of a specific mitigation effort. NEPA does not require the agencies to distinguish the past and ongoing effects of all the mitigation projects Bonneville has funded over the 40-year history of the Northwest Power Act,

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the Lead Agencies determined expected benefits from proposed mitigation measures, given the lack of specificity in the list of those measures. 252 COUNCIL, 2018 COLUMBIA RIVER BASIN FISH AND WILDLIFE PROGRAM COSTS REPORT (2018). Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 70 Furthermore, it appears that the Lead Agencies exaggerated the benefits of the proposed measures. The Lead Agencies provide summary tables in the BA that compare proposed mitigation measures to current conditions for each species by life history stage.253 Factors are color coded to represent anticipated effects: green for positive effects, gray for no changes, and yellow for negative effects. The summary tables also include plus, minus, and equal signs to denote whether there are anticipated benefits at each life stage. These tables appear skewed to illustrate anticipated benefits where, in reality, benefits are immeasurable or unsubstantiated. The statements supporting positive ratings are all qualified as slightly, likely, and potential. This suggests that there is very little certainty that this suite of measures will add up to measurable change in the trajectory for Chinook and steelhead populations in the Columbia River. Furthermore, the Lead Agencies do not describe the analyses or standards used to determine why a positive, neutral, or negative effect is anticipated. The Lead Agencies could characterize a very small (less than 1%) change in a metric as a positive effect, despite not having performed a statistical analysis or even indicated a standard to justify that finding.254 As such, the summary tables are effectively a list of conclusory statements. The Lead Agencies must explain how they reached these conclusions and their rationale for characterizing minimal changes as positive effects. The Lead Agencies apparently assume that a dozen slight and minor improvements at various life stages for Chinook and steelhead will cumulatively constitute sufficient evidence of improvement to justify the suite of measures to be included in Preferred Alternative. The Lead Agencies do not provide a rational connection between the incremental improvements and measurable benefits to justify this assumption. The remainder of this section considers quotes from the summary tables that serve as specific examples of the Lead Agencies unsubstantiated claims with respect to positive effects. 253 List of summary tables from Appendix V BA: Table 3-6 SR Fall Chinook; Table 3-10 SR Sockeye; Table 3-18 SR Steelhead; Table 3-26 SR Spr/Sum Chinook; Table 3-34 UCR Steelhead; Table 3-41 UCR spring Chinook; Table 3-49 MCR Steelhead; Table 3-52 LCR Coho; Table 3-55 LCR Chinook; Table 3-58 LCR Steelhead; Table 3-62 LCR Chum (cut and pasted from chinook section); Table 3-65 UWR Chinook (cut and pasted from Columbia stocks); and Table 3-68 UWR Steelhead. 254 Confidence intervals (standard deviation) were provided to the Lead Agencies for the NOAA COMPASS model results for juvenile survival, but the Lead Agencies do not include that data in the BA summary of model results. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 71 Potential positive effect from continued tributary habitat restoration. The Lead Agencies identify a set of implementation metrics to be accomplished in the first five years and total fifteen years of the BA.255 The metrics are identified for Chinook and steelhead species separately; however, in many cases these species overlap. The Lead Agencies proposed habitat program metrics are identified in Tables D.2 and D.3 in Appendix D to the BA. However, there is no analysis in the summary tables or elsewhere to demonstrate the how the Lead Agencies intend to achieve these metrics or what positive biological effects are expected. It is not clear if the metrics will be captured specifically for each species or whether individual actions that benefit both species will be double counted. Also, there is no connection between the proposed habitat metrics and potential benefits to salmon and steelhead. No response metrics are provided to demonstrate expected biological benefits. For the upper Columbia/East Slope Cascades Major Population Group (MPG), the Lead Agencies provide no information on where the actions will take place to achieve the proposed metrics from Table D.2. The Yakama Nation is the primary implementor of BPA mitigation funding in this region. Nevertheless, the Yakama Nations staff struggled to understand how these metrics were set and where they would be achieved. The current level of funding does appear not suitable to achieve the metrics proposed. In addition, habitat funding in the upper Columbia region has been reduced by over 10% since 2016.256 Therefore, less habitat work will be implemented than could have been implemented under the No Action Alternative if 2016 levels of funding were maintained. Moreover, with regard to the metrics set forth for upper Columbia/East Slope Cascades MPG in Table D.2, a Yakama Nation consultant reviewed the metrics with the following responses: Flow Protected 29CFS: In the mainstem Lower Wenatchee, this action would have almost no measurable biological benefit. If it were conserved in smaller streams currently flow limited and used by spring Chinook, then it could definitely have an impact. Most streams that would benefit from more water and have spring chinook in them are not flow limited or dont have significant irrigation activity the main exceptions being the Twisp River, upper Methow, and upper Wenatchee. There may not be a lot of meaningful opportunities for this metric. In addition, water purchases have had a cost of $185,000 to $249,142 per cfs, which calculates to $5,300,000 to $7,200,000 for 29 cfs. Water acquisitions are almost always multiyear and are extremely detailed negotiations, which take time away from pursuing other restoration actions. From a cost point of view, buying 29 cfs would burn at least two years of Upper Columbia Habitat Restoration Project (UCHRP) construction budget. For those reasons, the current level of funding is not suitable for achieving that metric. Flow Enhanced 5,309 acre/feet: Late season water releases do not seem to work very well. Specifically, enforcement of the turn-off has been a big problem. Also, 255 DEIS at Appendix D, Tables D.2 and D.3. 256 The Columbia Basin Fish & Wildlife Program, BPA (www.cbfish.org) (last accessed April 13, 2020). Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 72 most of the damage to fish gets done during the summer and keeping a small amount of water in the stream during the fall is mostly window dressing. There may be a water lease scenario that is beneficial for fish and is also enforceable, but those scenarios are difficult to find in the upper Columbia. Entrainment Screening 5 screens: Most irrigation intakes within anadromy are currently screened (with the exception of the Okanogan Subbasin) and therefore five screens seem like a reasonable number. Habitat Access 5 miles: The UCHRP is currently working to restore access to thirteen miles of good/excellent potential steelhead and spring chinook habitat. There is another ongoing project which will likely provide access to over ten miles of excellent steelhead habitat. Restoring five miles is shortchanging the potential benefit. Restoring habitat access is one of the easiest ways to alleviate the density dependence issues seen throughout the Columbia Basin; the BA shouldnt be setting the bar this low. As we move past the five-year mark, well need significantly more funding to start working on passage in small streams where there are multiple barriers per mile and the cost will be significantly higher. Stream Complexity 8 miles: The UCHRPs ten-year implementation plan identifies individual projects totaling sixty-five miles in the upper Columbia. From 2009 to 2019, the UCHRP restored twenty-one and a half miles of stream and side channel habitat and its difficult to say that work moved the needle very much. Spring chinook are currently at the AMIP trigger, as are steelhead. Under current conditions and priorities, the UCHRP could construct eight miles of habitat complexity in five years. Riparian Habitat Improved 68 acres: Riparian restoration is a long-term investment, which may not show benefit for ten years or more. Although the UCHRP does significant riparian restoration with every habitat complexity project, we only have one acre designated for specific riparian improvement in our ten-year implementation plan. Restoring sixty-eight acres seems like a reasonable amount of standalone riparian restoration. Riparian condition tops out at being the third highest ranking limiting factor in most of the upper Columbia, and in many AUs its much lower. Perhaps on small streams where the riparian can provide shade within five years. On larger streams (and most spring Chinook Critical Habitat are that) the benefit of riparian wont be seen for generations. Riparian restoration is relatively expensive and if the UCHRP were going to try to achieve sixty-eight acres in five years, wed need additional funding or would have to scale back passage and complexity work. For all the MPGs, the Lead Agencies have not coordinated with the primary implementers of mitigation to determine whether these metrics are needed to address the highest limiting factors and whether they are even feasible to achieve. In biological assessments associated with other federal actions, the Lead Agencies coordinated with the local implementers to ascertain what actions were needed and what biological benefits may be achieved through those proposed actions. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 73 In addition, habitat funding in the Snake River region has been reduced by over 10% since 2016,257 so less habitat work will be implemented than could have been implemented under the No Action Alternative. Accordingly, with regard to the Table D.2 metric, a Yakama Nation consultant reviewed the metric with the following response: Stream Complexity 8 miles: In the Grande Ronde, restoring eight miles of stream complexity in the next five years or twenty-four miles in the next fifteen years across the entire Grande Ronde/Imnaha basin will not be adequate to recover Snake River Chinook. The Lead Agencies must explain how, based on these metrics, they concluded that tributary habitat will result in positive effects. Existing and future habitat improvements will likely improve tributary water temperatures and turbidity levels. Tributary water temperatures and turbidity levels are not included as metrics evaluated in the Lead Agencys commitments in Tables D.2 and D.3. The Yakama Nation is therefore unclear as to why the Lead Agencies included these metrics in the summary tables and how the metrics are relevant to the conclusions therein. At any rate, Lead Agencies must explain how and to what degree improvements to tributary water temperatures and turbidity levels will result in a biological benefit to salmon and steelhead. In addition, the Lead Agencies fail to provide a rationale that connects the proposed habitat metrics in Tables D.2 and D.3 to the anticipated biological benefit for the species identified. It is unclear if proposed efforts will achieve the proposed metrics or whether achieving these metrics will benefit the target populations. The Lead Agencies must provide a biological explanation to demonstrate that the proposed metrics will address the primary limiting factors for the target species and how much response would be expected in life state survival. Flexible spill plan is expected to slightly increase non-turbine passage, and therefore survival. The COMPASS model estimates change in survival, but the Lead Agencies choose to infer benefits to survival based on powerhouse passage.258 The only metric that consistently shows significantly positive results from all COMPASS modeling for Flex Spill is powerhouse	particularly given that Bonneville now uses over 600 contracts annually to implement its Fish and Wildlife Program. In addition, the Agencies 2020 CRS Biological Assessment includes analysis of the implementation and effectiveness of both tributary habitat restoration actions and the CRS overhaul. Although the Northwest Power Act requires Bonneville to fund mitigation consistent with the Northwest Power and Conservation Councils (Council) Columbia River Basin Fish and Wildlife Program (Program) and the purposes of the Act, no statutory provision requires the co-lead agencies to undertake separate analyses regarding the efficacy of such mitigation. Rather, the structure and processes of the Act create a presumption that mitigation measures and projects recommended for implementation by the Council are indeed an effective means for addressing mitigation under the Act. First, the Council develops its Program based largely on the recommendations and expertise of fish and wildlife managers. The mitigation projects that the Council recommends to Bonneville for funding derive from their Program. Further, the Independent Scientific Review Panel periodically reviews the mitigation projects under to certain statutory criteria that, for example, include examining whether projects are based on sound scientific principles and benefit fish and wildlife. 16 U.S.C. 839b(h)(10((D)(iv). These statutory processes for vetting and reviewing implementation of mitigation projects provide a reasonable basis for the co-lead agencies to rely on these projects being effective. In addition, for fish and wildlife managers that implement Northwest Power Act mitigation through Fish Accord agreements with the co-lead agencies, the managers and co-lead agencies have agreed that such mitigation projects are consistent with the Councils Program, the underlying assumption being that the mitigation projects address appropriate obligations under the Council Program, and do so effectively. Further information about the policies and mandates of the Northwest Power Act and other statutes is in Chapter 5.1.2, and Chapter 8 discusses how the co-lead agencies complied with various law, including the ESA and Northwest Power Act. With regard to the concerns about funding levels noted in the comment, funding decisions are not being made as a part of the CRSO EIS process. However, a range of potential Bonneville Fish and Wildlife Program costs are included to inform the broader cost analysis for each alternative in the EIS. By analyzing a range of costs, Bonneville reflects the year-to-year fluctuations related to managing its program and also acknowledges the uncertainty around both the magnitude of biological benefits and the potential impacts on funding, including the timing of funding decisions. Future budget adjustments to the Fish and Wildlife Program would be made in consultation with the region through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. Ultimately, the FEIS examines the status quo through the NAA in terms of the existing environmental conditions with ongoing mitigation. The anticipated effects of the other alternatives examined builds on the NAA analysis. Ultimately, as the FEIS says in section 5.2.1, Outside of the specific mitigation measures that have been identified in the CRSO EIS, changes to mitigation programs, like the Bonneville F&W Program, are not being made through this EIS process. As discussed in section 7.7.21.1, in 2016, Bonneville's F&W Program budget was $267,000,000, and the Lower Snake River Compensation Plan (LSRCP) budget was $32,303,000. When these budgets are adjusted to represent 2019 dollars, they become $281,536,000 and $34,062,000, respectively, which are the budgets used under the No Action Alternative. For the Preferred Alternative, Bonneville would continue funding the operations and maintenance of the LSRCP, consistent with the No Action Alternative. Bonneville's F&W Program costs under the Preferred Alternative are estimated to range from no change from the No Action Alternative to a decrease of approximately 17%, or approximately $47 million, annually. Bonneville's fiscal year 2020 decisions to adjust the F&W Program budget to $249 million and the LSRCP budget to $30.5 million (BP-18 Rate Case) are consistent with the range of costs analyzed for the Preferred Alternative. The estimated costs are further detailed in Appendix Q, which provides an estimate of the total cost for implementing, operating and maintaining the system under each of the CRSO alternatives. These costs include capital investments, routine and non-routine operations costs (including extraordinary maintenance (NREX), and mitigation costs including fish & wildlife mitigation costs. The comment also equates funding quantity with mitigation quality, a relationship the comment does not justify or otherwise support. Moreover, the so called budget reductions, can in part be seen as corrections designed to bring budgets in closer sync with actual spending capacity of the entities implementing mitigation, many of whom have historically had budgets that exceeded practical spending levels. In addition, the comment fails to account for the fact that the cited budget reductions to Bonneville's Fish and Wildlife Program in 2018 were, in part, to offset the cost of spill operations to benefit fish. Finally, the comment does not acknowledge ongoing efforts that could conclude with a greater amount of existing funding going to on-the-ground mitigation. For example, as part of the 2018 BA, and as proposed to continue in the 2020 BA, Bonneville is working with the Council, NMFS, and state and tribal fisheries managers to develop a strategy to strategically realign research, monitoring, and evaluation of tributary habitat mitigation projects. This new strategy will explore how to more cost-effectively obtain the studies and evaluations while securing additional work on-the-ground that benefits anadromous fish more directly. Regarding the flexible spill operation associated with the Preferred Alternative, as noted in comment response 6299-47, in its analysis of effects, the Draft EIS used current high quality information, including models and studies published in peer review science journals. Specific to salmon and steelhead, the agencies used two primary modeling approaches, which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill operations on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts on juvenile migrants. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. This EIS analyzes the effects of operation, maintenance, and configuration of the CRS projects. The analyses used in this EIS were for the purposes of comparing the effects of the Multiple Objective alternatives for operation, maintenance, and configuration of the CRS projects to one another and to the No Action Alternative. Habitat mitigation program descriptions are discussed briefly in the No Action Alternative in Section 3.5.3.3 to give the reader the general information on these programs. For the purposes of comparing alternatives, however, a more detailed description is not needed. Chapter 7 describes programs that would continue as well as new mitigation under the Preferred Alternative. The scope of this Draft EIS is the operation and configuration of CRS projects; a complete analysis of all habitat programs and the development to the specificity suggested in this comment is beyond this scope.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				passage.259 Otherwise, most of the COMPASS model outputs for all species do not demonstrate more than 1% to 3% improvements in juvenile survival.260 Survival rates for upper Columbia steelhead juveniles is negative.261 Therefore, it appears that the Lead 257 The Columbia Basin Fish & Wildlife Program, supra. 258 DEIS at 7-94, 7-95, 7-100, 7-102. 259 Id. 260 Id. 261 DEIS at 7-95. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 74 Agencies expectations regarding Flex Spills effect on survival runs counter to the evidence before them.262 The Lead Agencies must explain this discrepancy. Travel time will slightly decrease with the flexible spill plan. The majority of model outputs for all species demonstrate no more than a 1% to 3% improvement. This is not a statistically significant improvement (as implied by the Lead Agencies use of qualifying language). Nevertheless, the Lead Agencies mark these actions with green highlight and a plus sign. The Lead Agencies must provide a rationale for concluding that a minor improvement in travel time will result in positive effects for fish. Continuation of predator management programs should decrease predation, slightly increase survival, and slightly reduce predation rates. It is true that predation may not worsen under status quo funding levels. However, pinniped and avian predation will not likely improve relative to the status quo without further investment and action. The Lead Agencies must explain how they concluded that continuation of these programs will increase survival and reduce predation rates. With significant investment, predator management may provide one of the best opportunities to provide incremental survival benefits at key life states. The Lead Agencies should provide additional measures to ensure improvements, including the creation of a basin wide coordination forum to ensure that all predator management agencies are coordinating their efforts to maximize results and to prioritize additional actions. Monitoring adult migration may assist in development of actions to reduce overshoot. The Lead Agencies must provide funding in the CRFM budget for additional actions to respond to information gathered in the monitoring of adult migration, such as installation of modified spill gates. Overshoot is already well-known concern. Without funding, it seems that the Lead Agencies simply propose to further monitor a known problem. The Lead Agencies must explain how they concluded that monitoring will result in practical development of overshoot reduction actions. C. The Lead Agencies fail to consider the role of local watershed groups in prioritizing and implementing mitigation actions with respect to habitat. The Lead Agencies provide a detailed description of their proposed Tributary Habitat Improvement Program in Appendix D to the BA. This description fails to recognize the importance and reliance on local watershed groups to help prioritize and implement habitat actions. The Lead Agencies should properly recognize the Yakama Nation and other co 262 It is also worth noting that tables associated with this statement appear to be cut and pasted without verification. The benefits of Flex Spill are identified for lower Columbia Coho, steelhead, and chum even though these species dont pass through more than one dam and Flex Spill may be constrained at Bonneville Dam due to erosion concerns. Yakama Nation Comments on the Draft Columbia River System Operations Environment Impact Statement 75 managers as active participants on the Tributary Habitat Steering Committee in order to fully evaluate the effectiveness of habitat mitigation proposals.	
6318	2	cindy.wright@seattle.gov	Seattle City Light	City Light sees the proposed PA as an improvement over the status quo and we are generally supportive of its stated intent. The PA provides for multiple structural, operational and mitigation measures that should directly benefit species listed under the Endangered Species Act (ESA), with limited impacts on power production. We support the operational measures in the management of the Grand Coulee/Lake Roosevelt operations that should provide improved instream flows downstream to benefit fish, while providing some operational flexibility for power production in the fall. Other actions, such as the increased drafting of the John Day Reservoir to reduce smolt predation by nesting Caspian terns and lamprey passage improvements in the lower Snake and Columbia River dams, should result in beneficial operational and structural changes. Many of the mitigation elements under the PA are carried over from past commitments and City Light continues to support those actions as identified in Table 7-5 of the DEIS. Additional "preliminary" measures under negotiation with various responsible agencies to benefit ESA-listed species (e.g., off-season spill for adult steelhead and bull trout at McNary; improving access for bull trout to perched tributaries in the Kootenai basin) also appear to address otherwise heretofore unmitigated effects of the CRSO on ESA-listed species.	Thank you for your comment. In developing the Preferred Alternative, one of the objectives was ensuring reliable and affordable power. The Preferred Alternative allows the co-lead agencies to continue to operate the facilities for their congressionally authorized multiple purposes, including fish and wildlife, water supply, navigation, flood risk management, and recreation. Improvements for lamprey were also included to support this species which is culturally significant to regional tribes. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Specifically for the comment on predation, on-going actions described in the No Action Alternative to reduce predation on migrating fish are included in the Preferred Alternative. In addition, water management actions ("Predator Disruption Operations" measure) in the John Day reservoir is expected to further reduce avian predation on migrating juvenile fish.
6318	3	cindy.wright@seattle.gov	Seattle City Light	Arguably the most significant operational change over the No Action Alternative in the PA is the continued implementation of the Flexible Spill Agreement initiated in 2019. We recognize that the increased spill under the PA is in t ended to improve smolt-to-adult return ratios (SAR) through the CRSO by reducing latent mortality. If projections in the PA based on a Comparative Survival Study (CSS) prove accurate (i.e., improved SAR for Snake River Chinook and steelhead by 35 and 28 percent, respectively) then our concerns will be largely mollified. The level of total dissolved gas (TDG) allowed under the PA (125 percent), however, is well above levels recognized in many studies to cause gas bubble trauma (GBT) in fish. As GBT can lead to direct and indirect adverse effects, including mortality, secondary disease, and increased predation, any reliance on the presumptions of the CSS model in particular the acceptance that 125 percent saturation can be generally regarded as safe-should be robustly verified. This level of super saturation is also notably well above water quality criteria for TDG applied to many other hydroelectric systems for the protection of aquatic animal health. Beyond these observations, the alternative Life Cycle Model(LCM) developed by the National Marine Fisheries Service (NMFS) projects potentially negative effects to Snake River Spring Chinook SAR from the PA in the event that latent mortality effects from fish passage are not improved by increased spill. As greater improvements in SAR are projected by both models in the Snake River dam removal alternative (i.e., M0-3) over the PA, the reliance on the output of the CSS model's projections in the PA in contrast to those of the LCM places great uncertainty on the potential outcomes and does not boost confidence.	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted in the comment, there is considerable uncertainty in the effects; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. This will include additional monitoring for the effects of exposure to elevated TDG and will be developed with regional input to ensure adequate monitoring is in place for various lifestages of salmonids, as well as monitoring of non-salmonid species. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
6318	4	cindy.wright@seattle.gov	Seattle City Light	The DEIS and appended Biological Assessment identify, at a high level, the monitoring that will be conducted to track the incidence of GBT in fish under the PA. The monitoring program to be implemented largely appears to be a continuation of the past GBT monitoring program implemented by the Fish Passage Center, the author of the CSS. We remain concerned about several elements of this monitoring because it may erroneously conclude limited adverse effect from GBT as a result of insufficient sampling. For example: We understand that current sampling of smolts to determine whether they are affected with GBT is conducted in bypass systems at the dams. Entering most bypasses requires smolts to enter at elevations significantly below the surface, which varies by dam; however, smolts using these bypass systems are not descending volitionally to expressly avoid high TDG levels, but rather as a pathway to emigrate. This descent greatly lessens the susceptibility to GBT. As TOG criteria are to be applied to surface waters of the forebay and tailraces of the dams, the fish being evaluated for GBT in bypasses are not likely the same fish that would be exposed to the highest levels of TOG experienced in fish passed with increased spill occupying the tailraces. Out -migrating smolts from upper river locations could be exposed repeatedly, if not continuously, to excessive levels of TDG. This scenario represents a chronic or (at least) sub chronic exposure profile for which increased injury is not fully considered in the DEIS. As the TOG water quality criterion under the PA allows surface waters to support TOG levels as high as 125 percent saturation from the tailrace of one dam downstream to the forebay of the next, it is possible that fish of many different species and life stages will experience pro longed exposure to TDG levels that have been shown to elicit GBT. The CSS model that supports the PA is based on smelt data. While most young salmon in the mainstem Snake and Columbia Rivers are smelts derived from tributaries, this is not an absolute (e.g., Hanford Reach Chinook). Early life stages (fry/parr) of such salmonid populations in mainstem habitats, as well as other non-salmonid native fishes, could be disproportionately exposed to higher levels of TDG as they will preferentially use shallow water habitats for rearing where TDG levels will be highest. In brief, monitoring of TDG should include multiple life stages and species. To ensure program effectiveness, adaptive management is to be exercised under the PA if adverse outcomes are recognized from biological monitoring. Unfortunately, the DEIS and BA provide few discrete commitments on the adaptive management program, with much remaining to be negotiated as a component of the ongoing ESA consultation. For example, while adult delays in migration are to be monitored, how exactly this will be done, and how/if the adults would also be monitored for GBT as a potential causal mechanism of the delay is not clear. Beyond temporary reductions in spill at each dam-in the event of increased GBT-it is unclear what specific adaptive management actions will be engaged if SAR values do not improve, or potentially, worsen.	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects of free swimming fish; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. This will include additional monitoring for the effects of exposure to elevated TDG and will be developed with regional input to ensure adequate monitoring is in place for various lifestages of salmonids, as well as monitoring of non-salmonid species. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
6318	5	cindy.wright@seattle.gov	Seattle City Light	We also reviewed the power analysis provided in the DEIS in consideration of how the PA and other alternatives could affect reliability, cost, and grid adaptability for accommodating changing demand and other renewable supply sources in the face of a changing climate. Through this review, we note that the DEIS relies on many inputs from 2017. Both resource prices and the regional supply and demand forecasts have changed since then. Topics for ongoing study by the Action Agencies should thus include the following: Resource prices and capabilities Need for, and availability of, integration resources Revising Load Carrying Capability estimates to look beyond supply co-incident with highest peak and to look at variable resources' ability to provide reliable service akin to resource participation in the Western Energy Imbalance Market Incorporating information about how utilities will replace retiring coal plants Incorporating utility plans to comply with state mandates BPA has made many strong efforts to model the complexities of the energy industry. Using Aurora, GENESYS, and GridView together is an excellent approach to consider how power supply and transmission interact to estimate price and revenue changes. City Light encourages BPA to continue this multi-faceted approach to studying changing load and resource conditions overtime. City Light asks that BPA commit to updating these models with current inputs on an ongoing basis, possibly aligned with the White Book publication or Regional Power Plan development.	The EIS uses the resource cost information from the Northwest Power and Conservation Council (Council) to estimate the potential range in costs of these replacement resources from the 7th Power Plan and the 7th Power Plan Mid-Term update in February 2019. For the 8th Power Plan, reference plant data was prepared by the Council between October 2019 to February 2020, which was not available in time for inclusion in the draft EIS. However, the final EIS incorporates updated costs for solar, wind, batteries, and gas resources as well the forward cost curves presented by the Council based on National Renewable Energy Laboratory (NREL) forecasts on March 3, 2020, to the Generating Resources Advisory Committee for the 8th Power Plan. The purpose of providing the range of replacement resource options is to present a reasonable range in potential costs. The EIS uses a load forecast prepared by the Council and published in July 2017 for the 2022 Resource Adequacy Assessment. This was the best available resource data at the time the base cases analysis was prepared for the draft EIS. The EIS acknowledges that there would be more demand for flexibility in the power grid as coal plants retire, and the value of this capability is likely to increase. As the region continues to add new renewable resources, Bonneville, and undoubtedly other entities studying resource adequacy in the region would be assessing the need for integration services for these new variable resources. In particular, any new resources connected to and sited within Bonneville's Balancing Authority Area would be evaluated in Bonneville's interconnection study process and be eligible for resource integration services in accordance with Bonneville's transmission tariff. The EIS analysis incorporated the current balancing reserves requirement into the base case analysis. Appendix I, Section 4.3 discusses the changes in hydrosystem flexibility for integrating new renewable resources. The Preferred Alternative includes some measures that increase flexibility such as increasing the operating range of the four lower Snake River dams and John Day by 0.5 feet compared to the No Action Alternative. Increases in system flexibility enable integration of more variable resources and support participation in the Western Energy Imbalance Market, which is one avenue for integrating variable renewable resources.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The EIS acknowledges that assumptions regarding coal capacity have changed since the base case was developed in 2017 and that the energy sector is undergoing transformation. To address this concern, the EIS considered various sensitivity analyses as well as examining two potential coal retirement scenarios. See draft EIS, Section 3.7.3.1, Availability of Coal Resources at pages 3-841-842 and Section 3.7.3.2, Table 3-123. The EIS presents the base case analysis first before discussions of information resulting from additional sensitivities and potential cost pressures. Specifically, the other regional cost pressures estimate the costs to the region of potential carbon policy compliance and coal retirements (for a description of all sensitivities, see Section 3.7.3.1 Additional Power Rate Sensitivity Analysis and Other Regional Cost Pressure Analysis). Regarding ongoing and future studies of reliability and adequacy in light of coal-plant retirements, Bonneville is participating in the regional Resource Adequacy efforts with the Council and the Northwest Power Pool. Additionally, Bonneville performs regular assessments of resource adequacy in its White Book and Resource Programs.
6318	6	cindy.wright@seattle.gov	Seattle City Light	While City Light sees the proposed PA as an improvement over current operations, our support is tempered by the numerous uncertainties and underlying assumptions inherent in the CSS model that supports the PA's expectations of improving SAR, and the scope of monitoring that will be conducted to gauge whether increased spill is helpful or harmful to the species it is intended to benefit. Success of the PA therefore requires an adaptive management program based on robust monitoring, with allowances and a commitment to change course as needed in a timely manner. At present, the adaptive management provisions are loosely identified in the DEIS and/or are reflected as still under negotiation. The Action Agencies should be prepared to adaptively manage the operations to remain flexible in the face of the changing climate's additive impacts that place fish, wildlife and energy resources at risk. This adaptability should include the consideration of further modifications of Snake River dam facilities or operations if the expected improvements in SAR are not reali zed in a reasonable timeframe to allow for a course correction. To this end, a 5-yeartime frame for reconsideration of the PA's monitoring results and outcomes would be consistent with the Army Corps' model for reissuance of Nationwide Permits that are also subject to Section 7 consultation requirements of the ESA, and allow for effects of the PA on SAR to be considered over multiple year classes of sal mon and steelhead. This time would also allow for regional stakeholders to advance the dialogue on reaching collaborative solutions to the energy and salmon restoration issues that confront us.	The framework for the adaptive management process is detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. While that includes the eventual duration of a study, the 5 year time frame suggested in the comment would be one of the possibilities discussed. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
6318	7	cindy.wright@seattle.gov	Seattle City Light	Finally, in order to sustain robust stakeholder involvement, City Light asks that the Action Agencies create a schedule for ongoing public review in the implementation and a timeline for supplementing or revaluating the EIS when conditions change.	Thank you for your comment. At this time, additional supplementation or re-evaluation has not been deemed necessary. However, the co-lead agencies plan on continuing stakeholder involvement through the various regional forums and public outreach
6344	1	Nicholas Nelson	Idaho Rivers United	In the attached documents, you will find detailed reasons why this DEIS is an extremely flawed and biased document, and arguments as to why this arbitrary 45 day comment period is inadequate and not in keeping with the law for review	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
6344	2	Nicholas Nelson	Idaho Rivers United	The Preferred Alternative (PA) proposed supports continuation of decades-long failed, incremental, status quo hydrosystem management and restoration measures that will not only not recover Snake Basin River anadromous fish runs in healthy and abundant numbers, but actually includes measures that most likely will expedite the extinction of anadramous fish to the Snake River Basin. While the agencies have made recommendation for the PA, the DEIS itself actually supports that the restoration of a free flowing, restored Snake River (which includes breach of the four Lower Snake River dams), as the only alternative that would lead to population increase sufficient enough to recover salmonids and steelhead to the required 4% average Smolt-to-adult (SAR) rate required to recover these species to sustainable adundance	Based on the analysis in the CRSO EIS, the Preferred Alternative will make a substantial contribution to improving Snake River anadromous fish runs, but broad-sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies used high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return (SAR) rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council (Council) recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. It should be noted that the 4% average SAR target referenced refers to the Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties.
6344	3	Nicholas Nelson	Idaho Rivers United	Further troubling is the documents clear bias and failure to objectively address issues like socioeconomics of a restored river economy, positive impacts to Southern Resident orca populations, water temperature, impacts on a changing climate, and a new Pacific Northwest energy portfolio; most likely because the only alternative that would have been acceptable would be MO3. Recommendation Regarding the CRSO-DEIS Alternatives The best available scientific evidence, when fully and objectively evaluated, shows that the CRSO-DEIS Alternative 3 (MO3) combined with 125% Total Dissolved Gas (TDG) spill at the lower Columbia River dams should be the preferred alternative to bring Snake River salmon and steelhead back to a sustainable, healthy population, and offers alternatives to address other Columbia River System functions. 3 The DEIS fails to provide the history necessary to understand the effects of the alternatives presented in the DEIS, the agencies biased analysis, a thorough analysis of the benefits of all alternatives, especially MO3, and was a rushed process, seeking to limit public participation and understanding.	The co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions and solutions for mitigating the effects of the CRS and achieving broader recovery objectives. The Preferred Alternative for long-term system operations, maintenance and configuration of the CRS presented in the Draft EIS is based on todays conditions and environment. Its also important to note that technology is quickly changing, as is the regions dynamic environment and energy market, and the region needs to consider new information and adaptively manage resources. The co-lead agencies recognize that no matter which alternative in the CRSO Draft EIS is identified as the Preferred Alternative, the identification would likely draw criticism from some stakeholders or sovereigns. The region includes stakeholders, sovereigns, and other interested parties with diverse and varied opinions on these very important topics, and many are strong in the belief that their perspective is the best path forward. It is important to keep in mind that factors, both human-caused and natural, that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the Columbia River System requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. The co-lead agencies look forward to participating in that discussion. The EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The co-lead agencies disagree, however, that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For Power and Transmission, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. This potential alternative has not been evaluated for direct, indirect and cumulative effects to other resources. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					of the objectives), and also meets most of all the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply and greenhouse gas emissions. It minimizing adverse impacts to communities and the economy. The Preferred Alternative is likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6344	4	Nicholas Nelson	Idaho Rivers United	The agencies repeated refusal to extend a comment period, first on the condition that 45 days is inadequate to evaluate a more than 5,000-page technical document, and additionally after evaluating the extraordinary circumstances of a national pandemic and the inability of the public to engage in this issue, a fundamental right in the NEPA process, prove the agencies refusal to be arbitrary and capricious.	See response to Comment 6344-1.
6344	5	Nicholas Nelson	Idaho Rivers United	Early History Once numbering in the tens of millions of fish, major changes have affected life cycle survival and recruitment of Columbia River Chinook Salmon, especially, Snake River strains, in the last 70 years. The Snake River Basin historically comprised almost half the Columbia River Basin Chinook salmon; returns consisting of 10 - 15 million adult fish annually. Large hydroelectric dams were built, starting with 4 on the Columbia River migration corridor, and by 1975, 4 more in the Lower Snake River. (Raymond 1988; ISG 1999; Budy et al. 2002). Declines in Snake River life cycle survival, productivity, and SARs coincident with each new dam are well documented (Raymond 1988; Petrosky et al. 2001; Wilson 2003; Schaller et al. 2014). Moreover, the agency did this despite advance notice that the dams would decimate the regions abundant salmon. The problem of passing migratory fish over dams on the lower Snake River was discussed with representatives of the U.S. Fish and Wildlife Service, State of Washington Department of Fisheries, Fish Commission of Oregon, Oregon State Game Commission, and the State of Idaho Department of Fish and Game, according to a 1947 Corps report on the dams. The consensus of opinion of these agencies was that any series of dams on the lower Snake River would be hazardous and might entirely eliminate the runs of migratory fish in that stream (Special Report on Selection of Sites, Lower Snake River: Oregon, Idaho and Washington, U.S. Army Corps of Engineers, March 1947)." 4 The primary purpose of these dams was the creation of a seaport at Lewiston, Idaho, but also included hydroelectric power and water for irrigation on adjacent lands. Unfortunately, the dams and accompanying reservoirs, particularly the cumulative effect from the 4 Lower Snake River dams have led to a collapse in anadromous salmon and steelhead, and many are near the brink of extinction (Nemeth, D.K. and R.B. Kiefer. 1999. Snake River spring and summer Chinook salmon-The choice for recovery. Fisheries 24(10):16-23). These fish were iconic to Idaho long before the dams were even a consideration.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That determination however is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6344	6	Nicholas Nelson	Idaho Rivers United	The native Lemhi-Shoshone Indians called themselves Agaidika, meaning salmon eaters. Redfish Lake in the Sawtooth Mountains of Idaho won its name from the glow 20,000 shimmering sockeye salmon created when they returned each fall to the waters of their birth. The serpentine Salmon River, with its famous whitewater rapids, was not named coincidentally. The Snake River once supported millions of salmon, a silvery horde ascending to their natal streams. Tribes living along the Snake and its tributaries partook of this abundance, and because of the bounty were among the wealthiest Native Americans in the region. For the Nez Perce Tribe salmon were a way of life. The tribe depended on salmon for sustenance, and its nomadic patterns followed the cycles of salmon returns. The Nez Perce creation story features salmon, which offered themselves to feed the people. Nez Perce Leroy Seth explains the importance of this keystone species to his people in the book, Salmon and His People: Fish & Fishing in Nez Perce Culture. The salmon are one of our best teachers, he said. We learn from them that we have to do certain things by the seasons. We watch the salmon as smolts going to the ocean and observe them returning home. We see the many obstacles that they have to overcome. We see them fulfill the circle of life, just as we must do. More than 150 years ago, in 1855, the Nez Perce Tribe signed a treaty with the United States. In it the Nez Perce retained total fishing rights on all streams and rivers within the boundaries of the original 13.4-million-acre reservation that extended outward to all usual and accustomed places, including the lower Snake and Columbia rivers. But as with other promises the United 5 States made to tribes throughout the country, the treaty stood in the way of progress, and salmon fishing opportunities in the usual and accustomed places have been all but eliminated. This story isnt only about the Nez Perce. The Columbia and Snake river fisheries supported all of the nearby tribes, many of which hold treaty rights that have not been upheld.	Thank you for your comment. The co-lead agencies appreciate your sharing the beautiful and symbiotic relationship many Tribal members have had with salmon and other fish. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
6344	7	Nicholas Nelson	Idaho Rivers United	Contemporary History With steadily declining runs, Snake River salmon and steelhead runs were listed as threatened or endangered under the Endangered Species Act (ESA). For the past 30 years, numerous mitigation efforts have been tried including fish hatcheries, natal habitat enhancements, barging, predator control, and fish-passage improvements. This CRSO-DEIS proposes more of the same, despite evidence that these have never worked to even curb the decline. Continuing in this vein will undoubtedly cause us to witness the extinction of Idaho salmon and steelhead. The sequence of ESA listing for Snake River anadromous fish is as follows: Snake River Sockeye, November 1991; Snake River fall Chinook and combined spring/summer Chinook, April 1992; Snake River Basin steelhead, August 1997 Recently, in 2017 only 250 pairs of wild Middle Fork Salmon River Chinook returned to Idaho, habitat that is considered some of the best and least disturbed of anywhere in the world. The 2019 returns of adult fish were near record lows for steelhead, sockeye, and Chinook salmon. These iconic and ecologically important strains are at immediate risk of extinction. In response to the ESA listings, recovery plans have been created, agencies have issued and reissued biological opinions (each of which have been found inadequate in federal court), and despite all efforts to recover salmon, we havent even been able to curb their decline, and now survival rates for these species are approaching extinction levels. Population trends of returning wild fish estimates have been masked, especially recently, by the increasing number of returning hatchery produced fish. Hatchery fish were intended as a 6 temporary mitigation measure for producing harvestable fish due to anticipated losses from the construction of the dams and reservoirs. Hatchery fish have also been shown to be less productive, lack much of the empirical benefits of wild fish, and can actually have adverse impacts to the genomics of wild fish populations (Christie et al. 2011).	Based on our analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Modeled predictions of the Preferred Alternative show potential to improve juvenile survival immediately with improved adult returns accruing as those juveniles return after several years in the ocean. These actions are expected to reduce the risk of extinction as estimated by NMFS in their modeling if latent mortality effects are reduced. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The comment incorrectly implies that hatchery fish are not relevant to the Draft EIS. However, hatchery origin fish are very important to Tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Hatchery programs are included in the No Action Alternative and would be expected to continue under alternatives MO1, MO2, and MO4, and certain hatcheries would continue under MO3. No new hatchery programs are considered as mitigation under any alternatives, but MO3 does include increased hatchery production due to short-term impacts from breaching the four lower Snake River dams. Under this alternative, hatchery programs would continue as proposed under the No Action Alternative, and a number of other mitigation hatcheries that are legally required would continue as well, but no new hatchery programs are proposed.
6344	8	Nicholas Nelson	Idaho Rivers United	Comments on ESA Listed Wild Salmon and Steelhead It is scientifically well established that the Columbia-Snake River hydrosystem of dams and reservoirs has had significant negative effects on regional salmon and steelhead populations. The Plan for Analyzing and Testing Hypotheses (PATH) was a regional analytical group created by court-driven processes. It analyzed salmon stock declines in a retrospective analysis surrounding the 2000 Biological Opinion (BiOp). The group observed that the construction of the four upper dams on the Lower Snake River was most likely responsible for greater decline in upstream (Snake River) stocks compared to downstream stocks (ODFW 2000). While not the sole source of salmonid mortality, the completion of the current hydrosystem in the 1970s certainly has been the primary cause of the last half-decade of population declines. The profound mainstem riverine habitat degradation caused by the hydrosystem pushed stocks of salmon and steelhead, and Snake River populations in particular, to dangerously low levels of abundance. Populations throughout the basin decreased to near-extirpation levels and were listed under the Endangered Species Act (ESA) as a result.	In its analysis of effects, the Draft EIS used current high quality data and best science, including models and studies published in peer reviewed science journals. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The Draft EIS did not utilize the PATH model, which is nearly 20 years old and does not take into account current operations. It is, therefore, not current high quality data. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6344	9	Nicholas Nelson	Idaho Rivers United	In the 20-plus years since salmonid stocks were listed, the federal action agencies have created a series of management plans that are required to consider salmonid recovery as it relates to hydrosystem management. The management plans have repeatedly taken the same approach of recovering listed salmonids; described by Judge Michael Simon in his remand of the 2014 BiOp as, ...hydro-mitigation efforts that minimize the effect of hydropower generation operations with a predominant focus on habitat restoration. () (NWF v. NMFS 2016). And, repeatedly, this approach has failed and been ruled legally inadequate while costing billions of dollars in the process. The federal hydrosystem or Columbia River System (CRS) cries out for a major overhaul in the words of Judge Malcolm Marsh in the 1990s.() (NWF v. NMFS 2016). NOAA itself has in 7 the past come to the conclusion that aggressive actions like breaching the Lower Snake River dams are the most effective means of ensuring Snake River salmonid survival and population recovery. In his 2016 Opinion and Order on the 2014 BiOp, Judge Michael Simon expressed hope when he ordered a new EIS for the hydrosystem. He envisioned a comprehensive EIS process that could encourage innovative, inclusive solutions and break through status quo actions that have kept salmon and steelhead populations on the precipice of extinction. The Columbia River System Operations (CRSO) DEIS unfortunately does none of that and only continues a long-cycle of biologically and legally inadequate hydrostem mitigation measures that shirk responsibility for salmonid declines	The co-Lead agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species as that is a broader goal with shared responsibility. Based on our analysis of the fish resources section of Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6344	10	Nicholas Nelson	Idaho Rivers United	This section of the comments revolves around the biological inadequacy of the Preferred Alternative selected by the action agencies. Numerous biological response metrics were modeled in the DEIS by both the Fish Passage Centers Comparative Survival Study (CSS) model and National Oceanic and Atmospheric Administrations (NOAA) Life Cycle Model (LCM). These models demonstrate that the benefits of the actions described under the Preferred Alternative (PA) are only marginally better than current hydrosystem operations under the No Action Alternative (NAA). Across all biological response metrics, the dam breaching alternative MO3 shows significant benefits to salmonids relative to the NAA. The selected PA and the biological assessment (BA) repeat troubling conclusions concerning salmonid recovery found in prior federal reports. These past reports have consistently failed to meet the requirements of the ESA and were ruled illegal in court.	The co-lead agencies understand and acknowledge that model estimates for the alternative that includes dam breaching showed the greatest predicted potential Smolt-to-Adult returns (SARs) for Snake River salmon and steelhead among the alternatives, as well as other effects to species in both the upper and lower Columbia River. The purpose of the analysis in the EIS is not limited to evaluating effects of ESA-listed salmon and steelhead. The CRSO EIS analysis provides analysis of multiple objectives and resources of the CRS water supply, hydropower generation, fish and wildlife conservation (including a variety of other species than salmon and steelhead), navigation, cultural resources, recreation and other environmental and socioeconomic resources. In addition, the EIS seeks to identify a Preferred Alternative that achieves a reasonable balance of multiple river resource needs and co-lead agency mission requirements. To that end, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6344	11	Nicholas Nelson	Idaho Rivers United	Congress has provided substantive policy direction regarding how the federal action agencies manage the hydrosystem, particularly in relation to salmon and steelhead populations that have been inordinately burdened by habitat and life-cycle modifications from the system of dams and reservoirs. A description of these guiding laws in particular is useful because it illustrates how far the DEIS has strayed from them in its analysis of salmonid recovery measures. One such policy directive is the ESA. Section 7 of the Act requires that the federal action agencies consult with the National	Chapter 8 discusses how the co-lead agencies complied with various law, including the ESA and Northwest Power Act. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to conserve species listed under the ESA. As described in the ESA itself, Section 7 requires the relevant agencies to, …insure that any action authorized, funded, or carried out by such agency…is not likely to jeopardize the continued existence of any endangered species or 8 threatened species or result in the destruction or adverse modification of habitat. () 16 U.S.C. 1536(a)(2). The biological assessment found in Appendix V of the DEIS has established the framework from which the consulted agencies will create a new BiOp in coordination with the EIS process. The BA creates a framework that will make ESA compliance under the ensuing BiOp difficult. A second policy directive comes from the Northwest Power and Conservation Council (NPCC) established under the Pacific Northwest Electric Power Planning and Conservation Act. The Act provides guidance for managing the hydrosystem in an equitable fashion for fish and wildlife. As the DEIS states, the action agencies also consider in their decision making the NPCCs Fish and Wildlife Program and Mainstem Amendments to the fullest extent possible. ().	Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Finally, the NMFS and USFWS Biological Opinions demonstrate that CRS operations, maintenance and configuration do not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. With regard to the comments about the policies and mandates of the Northwest Power Act, the final EIS has been edited to provide more detailed discussion of those mandates and how the Agencies comply with them. See Chapter 5.1.2.
6344	12	Nicholas Nelson	Idaho Rivers United	Concerns The PA does not provide actions that will recover ESA-listed salmon and steelhead, or ensure that their existence is not jeopardized. The BA ignored the fact that the CRS hydrosystem continues to be the primary limiting factor for Snake River salmon and steelhead recovery. The PA instead focuses on ancillary effects like tributary habitat and predation as limiting factors for recovery. The BA also chose to focus on segmented life stage survival, rather than readily available SAR information. It also does not illustrate the current very low current abundance and SARs of Snake River salmonid populations, across all Evolutionarily Significant Units (ESU) and Distinct Population Segments (DPS). In the face of rapidly warming climate that has begun to negatively affect salmon life stages, the failure of the PA to recommend strong recovery actions will jeopardize the already weak stocks of Snake River salmonids. As the 2016 Court Opinion and Order pointed out, NOAA Fisheries own Consultation Handbook recognizes that the longer a species remains at low population levels, the greater the probability of extinction from chance events, inbreeding depression, or additional environmental disturbance. () (NOAA Fisheries).	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
6344	13	Nicholas Nelson	Idaho Rivers United	Recommendations 1) The NPCCs established goal of 2-6% SAR with a 4% average for Snake River and Upper Columbia River salmonid stocks should be adopted in this DEIS. 9 Snake River stocks of salmonids enjoy access to hundreds of miles of pristine wilderness streams for spawning and rearing. A large amount of this interior habitat found in Idaho is also projected to be resilient to riverine temperature increases due to climate change in the future and is often termed climate refugia. This habitat contributed to Snake River spring/summer Chinook stocks that once accounted for 40% of all Chinook returns throughout the entire Columbia Basin. Yet, these stocks are some of the most threatened in the entire basin. SARs less than 1% have been correlated to population declines in Snake River stocks, with population growth not occurring until SARs reach 2% across all Snake River ESUs and DPSs. () (Mamorek et al., 1998). Spring/summer Chinook SARs average below 1% and steelhead SARs are just above the 1% mark. These SAR trends are all the more concerning when current abundance levels of these stocks are taken into account. Snake River spring/summer Chinook have a recent ten-year average of just 17,600 fish over Lower Granite dam. Healthy and harvestable escapement goals established in the Columbia Basin Partnership (CBP) Task Forces Phase 1 Report call for 127,000 wild Chinook returning to spawning grounds. Similarly, Snake River steelhead average just 30,800 to Lower Granite dam, while the CBP healthy and harvestable goal is 105,000. Snake River sockeye have barely warded off extinction for decades and average only 100 wild fish to spawning grounds, while CBP goals call for 9,000 sockeye annually returning to the Stanley Basin lakes. () (CBP Task Force, 2019). Far from overly idealistic goals, the CBP modeled these benchmarks in many cases off of abundance levels from the 1950s and 1960s before the hydrosystems completion. In order to achieve healthy and harvestable numbers the NPCC SAR goals must be met and a 4% SAR average especially must be met. Including tangible SAR goals in the DEIS would help action agencies evaluate the effectiveness of each alternative and how each will realistically protect vulnerable salmonid stocks.	The EIS is being developed to update the operations, maintenance, and configuration of the 14 dam operated as the CRS. Each of these dams has multiple authorized purposes that much be met, including fish and wildlife. Several of the objectives were to improve conditions for fish. However, is it not a salmon recovery plan. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. It should be noted that the 4% average SAR target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The co-lead agencies disagree with the comment that notes a SAR of 2% will only maintain a population. A SAR rate of 2% can lead to significant population growth given adequate productivity and habitat quality. The COMPASS and NMFS Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. In compliance with ESA, the co-lead agencies submitted a biological assessment to NMFS and USFWS (Appendix V). In this Final EIS, the Biological Opinions from NMFS and USFWS can be found in Appendix V, completing this projects ESA consultation.
6344	14	Nicholas Nelson	Idaho Rivers United	1a) The action agencies should analyze the probability of SAR benchmarks being achieved through the selected PA and other alternatives. The 2019 CSS report included the probability of each CRS DEIS alternative meeting SAR benchmarks in the future. It concluded that only the dam breaching alternative MO3 consistently predicted spring/summer Chinook and steelhead would meet the 4% SAR goal and also had a 10 lower end of predicted SAR range that was above 1%. Meanwhile, the PA resulted in only marginally better SARs than the NAA. For both of the aforementioned species, the PA did not meet the 4% SAR target, nor did it successfully prevent the lower range of the species SARs from dipping below 1%. The action agencies should include this analysis in the DEIS in order to better illustrate the risk of further decline and extinction that the PA places on salmon and steelhead stocks. Finally, non-federal alternative MO34, that was only analyzed in the 2019 CSS, includes Lower Snake River dam breaching as well as 125% TDG spill at the lower Columbia dams. This alternative saw the greatest increases in SARs relative to the NAA and consistently met recovery targets as well as safeguarded Snake River salmonid stocks from further decline across all river conditions.	The co-lead agencies used current high quality information and the best available science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the NPCC recovery targets for the region) as a result of the preferred alternative. The COMPASS and NMFS Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. It should be noted that the 2-6% SAR target referenced in this comment refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on our analysis of the preferred alternative, we feel our actions will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which only contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species as that is a broader goal with shared responsibility. Based on our analysis of the fish resources section of Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call however is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
6344	15	Nicholas Nelson	Idaho Rivers United	2) The action agencies should utilize SAR metrics that measure the full effects of the CRS on salmonid life-cycle survival into their analysis. SARs are reported from the modeled effects of each alternative as well as the preferred alternative. CSS modelling in the DEIS demonstrates a 170% increase in SAR from the NAA for Snake River spring/summer Chinook and 178% SAR increase for Snake River steelhead in the event of dam breaching under alternative MO3. However, there is no further discussion as to the benefits or meaning of these SAR increases in relation to salmonid population status. SARs under the PA are CSS-modeled to increase from the NAA 35% and 28% for Snake River spring/summer Chinook and steelhead, respectively. In both MO3 and the PA, SARs increase, yet the DEIS does not discuss the significance of the differences between each alternative. Further, the biological assessment portion of the report focuses on individual life stage survival and includes no mention of the relationship SARs have to these metrics. SARs, when measured from the uppermost dam, are important in their ability to parse out the large effects of the hydrosystem in particular on salmonid life-cycle survival both during mainstem migration and in subsequent life stages. In choosing not to thoroughly incorporate SAR metrics into their analysis, the nature of the action agencies analysis changes in several ways.	The co-lead agencies did utilize SAR metrics in the Draft EIS analysis. Both CSS and the NOAA Life Cycle models predicted SARs from Lower Granite Dam to Bonneville. Further, to provide additional interpretation on the meaning of SAR differences, the Draft EIS presents changes in abundance for select populations (see Chapters 3 and 7). Different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the NOAA COMPASS model, juvenile Snake River Spring/Summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NOAA Life Cycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase - smolt-to-adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River Spring/Summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for meeting salmon and steelhead objectives. One simply predicts adult return increases an order of magnitude higher than the other.
6344	16	Nicholas Nelson	Idaho Rivers United	2a) The action agencies should include in the DEIS both historical as well as lower river - upper river SAR comparisons for Snake River salmonid stocks, as observed in CSS annual reports. 11 Firstly, the impact the CRS hydrosystem has had on salmonid stocks is minimalized in the report. However, when comparing SARs historically and geographically across the CRS system, important differences are illuminated. SARs for Snake River salmonids in the 1960s, when four mainstem Columbia dams were in place, averaged 4.3% for spring/summer Chinook and 7.2% for steelhead. () (FPC, 2019). Currently, with 8 dams on the mainstem Columbia-Snake system Snake River, near term SAR averages are 0.8% for spring summer Chinook and 1.5% for steelhead.() (FPC, 2019). The relationship between the number of dams and SARs plays out not only temporally, but also spatially. Middle Columbbia stocks of salmon and steelhead from the John Day and Yakima rivers share the same lower river conditions, ocean conditions, and predation pressures as upriver Snake River stocks. SARs for these Middle Columbia stocks, which must migrate through 3-4 dams, are much higher than those for Snake River stocks. They are well within the 2-6% SAR range deemed necessary for recovery and hit the 4% SAR target for rebuilding healthy and harvestable populations often. () (FPC, 2019).	The co-lead agencies used current high quality information and the best available science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the preferred alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the NPCC recovery targets for the region) as a result of the preferred alternative. SAR values reflect the methods used for estimation, and this should be taken into account when comparing estimates against the Council's regional SAR objectives for recovery. The Council did not prescribe a specific method of SAR calculation. SARs reported by hatcheries using coded wire tags often incorporate a harvest correction factor for ocean, recreational and tribal harvest. Due to the different approaches of the models, including the length of the historical survival time series, use of different hatchery and natural origin populations, and other factors, the two models estimated substantially different SARs under the No Action Alternative for Snake River spring Chinook: 0.88% from the Compass model, assuming no latent mortality, and 2.0% SAR from the CSS lifecycle model, which is at the low end of the Council targeted range for recovery. Regarding your suggestion to compare lower river to upper river SARs, the co-lead agencies have used caution when comparing SARs between different populations and ESUs and river basins as it is extremely challenging to find two populations that are suitable references for each other. The ISAB has noted those challenges in using that line of reference specifically related to comparisons of John Day populations to Snake River populations (ISAB 2020-1).
6344	17	Nicholas Nelson	Idaho Rivers United	2b) The action agencies should prioritize the reporting of SAR metrics over individual life stage survival. This will help reduce uncertainty concerning the outsized, latent mortality effects the hydrosystem has on salmonids throughout their riverine and marine life stages. Secondly, the DEIS compartmentalizes survival metrics into past the concrete measurements at individual dams from forebay to tailrace for juvenile salmon as well as reach survivals between dams. The report relays individual response metrics such as water transit time (WTT) and powerhouse passages (PITPH), but fails to associate these metrics with the cumulative experience of salmonid hydrosystem migration. These measurements, when compartmentalized, fail to capture the relationship that these factors as well as delayed arrival times at the Columbia estuary have on salmonid fitness as they transition into subsequent ocean life stages. The CSS annual report synthesizes research in which the WTT and PITPH variables were associated with reductions not only in in-river survival, but also ocean survival and SAR survival. In other words, these variables strongly associate delayed or latent mortality effects of the hydrosystem with reduced SAR survival during the entirety of salmonid smolt to adult life stages. In the empirical statistical model used by the CSS, SAR survival metrics also implicitly capture all sources of mortality across the measured life stages. 12 A more thorough examination of SAR metrics as modeled by the CSS should alleviate concerns the action agencies have with the effects of higher total dissolved gas (TDG) levels, upstream adult passage success, smolt transportation efficacy, and uncertainty in the relationship between latent hydrosystem mortality and marine life stage salmonid survival. The comprehensive nature of SAR metrics capture the benefits that increased river flow brings to salmonid in-river migration compared to transportation. In the case of delayed or latent mortality, SAR metrics strongly associate the effects of hydrosystem experience with reduced estuary and ocean survival in salmonids.	SAR is an important metric, and a key one used throughout the Draft EIS. The co-lead agencies agree that it captures population level effects. However, a SAR estimate will exhibit variability of several orders of magnitude as it is influenced by a vast number of factors, many of which are interrelated. This makes SAR a very problematic metric for evaluations with great risks of masked effects, spurious correlations, exaggerated response relationship. On the contrary an estimate of survival though a spillway is much more straight forward to determine which presents better conditions for fish. However, it tells you little about cumulative population level effects. The metrics at all scales are important tools which is why the EIS used many metrics including SARs. Both the CSS and NMFS lifecycle models incorporate the variables noted in this comment such as total system travel time, arrival time to the estuary, ocean conditions etc. These interactions are incorporated into the results produced by the models for this EIS analysis. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored and effects from other sources such as harvest, ocean mortality, and straying will also be accounted for to the extent possible. There are additional scientific uncertainties regarding mechanisms and magnitude of delayed mortality or carryover effects resulting from experiences migrating through the hydrosystem. Several studies using acoustic or active tags have monitored the survival of smolts through the estuary and coastal ocean below Bonneville Dam after barging vs. migrating in river (Eder et al. 2009, Dietrich et al. 2016, Rechisky et al. 2012), and following passage through eight dams vs. 3-4 dams (Rechiskyet al. 2013). While there were indications of effects of barging, there was little evidence for delayed survival effects of multiple dam passage in the one to three weeks following passage at Bonneville. This remains an active area of research. Eder, K., Thompson, D., Buchanan, R., Hublein, J., Groff, J., Dietrich, J., ... & Loge, F. J. (2009). Survival and travel times of in-river and transported yearling Chinook salmon in the lower Columbia River and estuary with investigation into causes of differential mortality. Final Report submitted to the USACE, Walla Walla District, Walla Walla, Washington. Dietrich, J., Eder, K., Thompson, D., Buchanan, R., Skalski, J., McMichael, G., ... & Loge, F. (2016). Survival and transit of in-river and transported yearling Chinook salmon in the lower Columbia River and estuary. Fisheries Research, 183, 435-446. Rechisky, E. L., Welch, D. W., Porter, A. D., Jacobs-Scott, M. C., & Winchell, P. M. (2013). Influence of multiple dam passage on survival of juvenile Chinook salmon in the Columbia River estuary and coastal ocean. Proceedings of the National Academy of Sciences, 110(17), 6883-6888.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6344	18	Nicholas Nelson	Idaho Rivers United	Final Recommendation The action agencies should select a modified alternative MO3 that includes breaching of the four Lower Snake River dams as well as increasing spill at the lower four CRS dams to 125% TDG. The currently selected PA does not adequately safeguard Snake River salmon and steelhead from further decline and extinction, especially when the deleterious effects of climate warming are considered. The DEIS obfuscates sound science that relies on comprehensive SAR survival metrics and induces uncertainty into what actions are best for salmonid recovery. The resulting PA is little more than a temporary measure that will include minor improvements to salmonid survival. It is a research and monitoring activity on factors such as delayed mortality and life cycle survival that have already been comprehensively modeled and studied over the past several decades. As evidenced in reports such as the FPCs CSS as well as the Southern Resident Killer Whales & Columbia/Snake River Chinook: A Review of the Available Scientific Evidence whitepaper by concerned scientists, restoration of the Lower Snake River via dam breaching would provide the most long-term certainty for recovery. () (Bain et al., 2020). The CSS model predicts up to 4-times higher SARs and return abundances from current conditions if a modified alternative MO3 is carried out. 13	The co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The COMPASS and NMFS Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The proposed operation in this comment was not proposed by the co-lead agencies or the cooperating agencies and was not analyzed as a multi-objective alternative in this EIS. However, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (i.e., increased incidence of blackouts). Without major additional of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5 percent of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion a year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts in the foreseeable future.
6344	19	Nicholas Nelson	Idaho Rivers United	Comments on Power Generation and Transmission General Comments In the Power Generation and Transmission section of the DEIS, Bonneville Power Administration (BPA) puts forth a number of arguments that appear to support anything other than the status quo, or status quo with minor modifications, will greatly increase Pacific Northwest power prices and lead to the possibility of rolling blackouts throughout the region. Nothing could be further from the truth. At one time, BPA provided valuable benefits to its customers. In part, those benefits were tied to the decimation of Idahos wild salmon and steelhead populations and led to the listing of these species under the Endangered Species Act. Subsequent legal actions led to significant annual mitigation costs imposed upon BPA. Court ordered mitigation has driven up power costs to BPAs preferred customers to a point well above the regional open market prices. Meanwhile, BPA spent down nearly one billion dollars of cash reserves in an attempt to keep its rates competitive while, at the same time, failing to recognize and respond to a rapidly changing energy picture in the northwest and across the country. This leaves BPAs customers, obligated by enforced contracts, paying excessive rates for power that others purchase from the open market at significant savings. Meanwhile, investor-owned renewable and carbon-free generation projects continue to be built across the northwest thus ensuring low-cost open market power that replaces obsolete coal generation that is being retired. Absent from this evolution is a debt-riddled Bonneville Power Administration. Finally, commenters are deeply disappointed that, during a NEPA comment period, BPA Senior Spokesperson Douglas Johnson sent the following email to several employees of the Seattle Times: From: Johnson,G Douglas (BPA) - DK-7 <gdjohnson@bpa.gov> Sent: Monday, March 30, 2020 3:08 PM 14 To: Rami Grunbaum <rgrunbaum@seattletimes.com>; Lynda Mapes <lmapes@seattletimes.com>; Hal Bernton <hbernton@seattletimes.com> Subject: BPA Finances and Snake Dam hydroelectric information Greetings, There are a number of facts and figures that are being misinterpreted during this important public comment period for the Columbia River Draft Environmental Impact Statement. Information correcting the record on those issues is included below. I hope you have had a chance to read the Executive Summary. You can find it at this link. 1) BPA sells power at a loss or BPA sells power for less than it costs to produce: BPA sells power to consumer-owned electric utilities PUDs, municipal utilities and utility cooperatives at a set wholesale price. If we have surplus electricity, we sell it on the spot market. Unfortunately, this market has been depressed for the past several years, which has negatively impacted BPAs secondary revenues. We rarely, get less money than it costs to produce. 2) The Snake River Dams account for 4% of the regions power. True but misleading. Not all of the utilities in the Northwest purchase power from those dams. The electricity generated by the Snake River Dams is consumed predominately by the consumerowned utilities listed above, many of which are in rural communities, and accounts for a little more than 10% of the electricity BPA sells to them. The cost of replacing the power from the dams would hit them in a disproportionate manner. Removing the Snake River Dams and replacing them with natural gas generation would increase the rates of PUDs, municipal electric utilities and electric cooperatives by 8.2 to 9.6%. If those dams were replaced by a combination of renewables, battery storage and other non-carbon measures, which may be more likely given current state renewable portfolio standards and other carbon legislative proposals, it is projected to increase those rates by 9.5 to 19.3%. See pages 25 and 26 of the CRSO draft EIS Executive Summary. 15 3) The Snake River Dams cannot produce 2,000 MW of Peaking Capacity: The lower Snake River projects provide more than 2,000 MW of sustained peaking capabilities during the winter, and a quarter of the federal power systems current reserves holding capability. The dams play an important role in maintaining reliability, and their flexibility and dispatchability are valuable components of the CRS see page 25 of the CRSO draft EIS Executive Summary. This is important because the Northwest is still a winter peaking region, meaning its highest consumption of electricity is during the winter not the summer. Between October 2009 and March 2018, there were 8,600 operational hours that the Lower Snake River Dams provided more than 2,000 MW of electricity. 4) BPA is becoming financially insolvent: By trimming $66 million of costs planned for the current two-year rate period, BPA held rates flat for the first time in more than a decade. Considering that between 2008 and 2018 BPA wholesale Power rates increased on average about 3.6% per year, this clearly demonstrates the financial discipline to bend the cost curve and provide low-cost, carbon-free hydropower to our public power utility customers across the Northwest. In addition, all three US credit ratings agencies consider BPA to have high, investment-grade credit. A major contributing factor to these ratings is our long-term contracts with our preference customers, the Public and Peoples Utility Districts, municipal electric utilities and electric cooperatives in the Pacific Northwest. 5) The Snake River Dams are expensive and near the end of their life: Major powertrain replacements for the Snake River Dam hydroelectric assets are not currently forecasted to occur within our 20-year system asset plan. Long-term planning analyses that calculate the optimal economic time to replace equipment based on current and expected equipment health, probability of failure and outage consequence, point to the late 2030s as the earliest replacement dates. In fact, most of the optimal replacement dates are spread between the 2040s and 2060s for the Lower Snake dams for turbine and generator replacements. The most recent work done at Ice Harbor includes an already installed improved fish passage turbine with another currently being installed and another on the way, which will further modernize and improve those hydroelectric components. 16 I hope you find this information helpful. If you have questions or need additional information, please contact me at 503-713-7658. Doug Johnson Senior Spokesperson, BPA	Bonneville provided clarifying information based on information included in the Draft CRSO EIS to correct inaccurate media reports. The clarifying information focused on how Bonneville collects revenue, the power characteristics of the four lower Snake river dams, and the impacts of breaching on Bonneville's customers. As discussed in Section 3.7.2.5, the spot market price is not directly comparable to Bonneville rates because Bonneville provides a high-quality power product that is backed by Federal Base System resources, which includes the Federal dams and the Columbia Generating Station. Bonneville firm power customers, thus, receive a power product that provides a reliable and stable supply of power at predictable prices set by Bonneville's statutory process. Spot market purchases, in contrast, are volatile, with supply not assured and pricing subject to market spikes. In regards to Bonneville's cash reserve declines, as discussed in the BP-18 rate proceeding, various factors have led to the decline in Bonneville's cash reserves. This includes declining loads, reduced market prices, an abundance of natural gas, and rising costs. Most of these factors are not unique to Bonneville, and are being felt by utilities both regionally and nationally. Bonneville has not ignored these pressures, but has taken a proactive action, such as developing both a strategic and finance plan. Those plans have guided Bonneville's recent competitive efforts, which include achieving a zero percent annual rate increase in BP-20 (before application of the Financial Reserve Surcharge). More recently, Bonneville's emphasis on financial management and controls also revealed an error in the method by which Bonneville accounted for its financial reserves between its business lines, resulting in the reallocation of over $180 million in financial reserves to the power business. With the continued focus on managing costs and building new opportunities for revenues, Bonneville expects to maintain its competitive position as the supplier of choice for its customers both in the near-term and long-term.
6344	20	Nicholas Nelson	Idaho Rivers United	The federal agencies, including BPA, spent four years and tens of millions of taxpayer dollars developing this DEIS. During the four years of development, BPA had every opportunity to address the above points during the drafting of the DEIS. Reaching out to the media in an effort to sway reporting while a comment period is open is inappropriate. While BPA will be able to respond to public comments during its review period, the public has no other opportunity in this process. In response to the email sent by Doug Johnson, Anthony Jones of Rocky Mountain Econometrics released a response to the five points outlined by Mr. Johnson. Mr. Joness are hereby included in the record and can be found in Attachment A.	Bonneville provided clarifying information based on information included in the draft CRSO EIS to correct inaccurate media reports. The clarifying information focused on how Bonneville collects revenue, the power characteristics of the four lower Snake river dams, and the impacts of breaching on Bonneville's customers.
6344	21	Nicholas Nelson	Idaho Rivers United	Specific Comments Page 3-790 Capacity and Generation the annual generation of the BPA hydrosystem is far less that the often-touted capacity of the system. The seasonal streamflows of the Snake and Columbia rivers are insufficient to allow generation anywhere near system capacity. According to Table 3-110 the generation capacity of the Dalles Dam is 2,052 megawatts (MW) yet the 80-year average (1929-2008) power generation is 823 average megawatts (aMW) or approximately 40% of capacity. For clarity, an average megawatt is the equivalent of generating one megawatt per hour, 24 hours per day times 365 days per year which comes out to 8,760 megawatt hours or 1 aMW. One troubling part of this analysis is the use of an 80-year data set. The same table states that, while the capacity of the four lower Snake dams is 3,483 MW, the combined generation is 1,100 aMW. Yet, the actual daily combined generation of these four dams from 20042019 (according to the ACOE Data Query site) was 963 aMW or, just 27.6% of capacity. The ACOE and BPA 17 consistently overstate the actual generation of the four lower Snake River dams in order to inflate their benefits. A month by month examination of the 16-year ACOE data set shows that, of the 963 aMW of generation at the four lower Snake River dams, 509 aMW was generated during the four months of springtime runoff when wholesale power values plummet due to a glut of energy. This leaves approximately 454 aMW to cover power demands over the remaining eight months of the year including the coldest and hottest months when the power is in highest demand. Examples include 34 aMW in August, 58 aMW in December, 74 aMW in January, and 81 aMW in February. Page 3-794 Generation Balancing Reserves, Dispatchable Resources, and Ramping Capability Industry special interests opposed to lower snake River dam breaching along with the ACOE and BPA claim that lower snake river dams uniquely provide valuable balancing reserves, spinning reserves, and ramping capability. This claim is overblown as all of the FCRPS dams have the capacity to provide those services. During the eight months outside of the spring runoff season, these dams have more inactive generators than active due to a lack of streamflow. Instead of operating a few generators at full load, more generators can be operated at partial load with the remaining capacity available to meet sudden changes in system operations. In 2018, a 129 MW modular Tesla battery	The comment is correct that hydroelectric projects typically generate less power on average than their nameplate capacity because the flow or water in the river varies. However, this operational characteristic is not unique to hydroelectric projects. Likewise, wind projects average generation is well below their nameplate capacity, mostly because the wind is not always strong enough for the turbine to generate at nameplate capacity. Solar projects, similarly, operate on average below their peak nameplate capacity. Even natural gas plants do not operate at full capacity year-round either; they typically reduce generation when demand is low such as at night, when there is a large supply of inexpensive power available on the spot market (often during spring runoff when hydropower has ample generation), and for maintenance. The use of a large data-set for hydropower planning studies is standard in the Northwest. The 80-year Modified Flows data set (https://www.bpa.gov/p/Power-Products/Historical-Streamflow-Data/streamflow/2010-Level-Modified-Streamflow.pdf) was developed by Bonneville, the Corps, and Reclamation with input from members of the Pacific Northwest Coordination Agreement (PNCA) and B.C. Hydro (other hydroelectric dam owners on the Columbia River System) as required by the PNCA and the Columbia River Treaty. Because river flows vary from year to year, a longer record provides a larger sampling of the range of flows that may be expected. Separately, the climate change analysis discussed in Appendices I and J and summarized in Chapter 4 Section 4.2.7, addresses the potential shift in the 80-year historical record with respect to how climate change may affect the conclusions of the EIS. The average generation modeled using an 80-year data set would differ from the generation in any given year or even the average of several years, as noted in the comment. The comment is correct that the four lower Snake River dams generation is typically highest in the spring, as is the case for most major hydroelectric projects in the region. The monthly shape of hydropower generation is included in hydropower modeling, such as the modeling used in the CRSO EIS. Please see Table 3-122 in Section 3.7.3.2 of the Draft EIS which shows the monthly shape for the No Action Alternative of the Columbia River System projects combined generation. Appendix J provides details of generation in the Exhibits. The four lower Snake River dams are not the only dams capable of supplying reserves and ramping capability. This responsibility must, in fact, be distributed over multiple dams to provide reliability through diversification and because any one project could rarely supply the total needed reserves. Indeed, as the comment suggests, turbines are generally operated not at full capacity but in-between their maximum and minimum limits so that generation may adjust to meet fluctuations in demand, to compensate for fluctuations in generation from variable resources, and to increase generation quickly in the event of a contingency. The EIS included battery storage as an option in the potential replacement resource portfolios and acknowledges that technology is evolving including batteries.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				was installed in south Australia in order to provide firming capacity for large-scale wind generation and to provide grid stability. At that time, The Australian Prime Minister derided the project as being a Hollywood project. Within 100 days of the contract signing the project was installed and online. In its first year the project saved ratepayers over 40 million dollars. At the end of January 2020, the Australian Prime Minister was pleased to announce a 50% expansion of the project that was expected to be online by the end of March 2020. This is an example of a real-world solution that the preparers of this DEIS seem unable to grasp.	
6344	22	Nicholas Nelson	Idaho Rivers United	Page 3-801 Competitive Pressure on Bonnevilles Power Rates Drafters provide a fair narrative from lines 24545-24555 but quickly veer off the rails by claiming that the spot market price is not directly comparable to Bonnevilles rates because Bonneville provides a high-quality power product 18 At the end of the day, electricity is simply electrons flowing through wires. There is nothing special about BPA power in fact, BPA itself sells a portion of its generation on the spot market often at a loss. The real issue here is that BPA has priced its power out of the market and the only reason that BPA is not in a direr financial situation is the 136 firm power customers who are locked into long-term contracts that expire in 2028. BPA Administrator Elliott Mainzer has made it clear in the media that BPA will enforce these contracts in court should Tier-1 contract holders attempt to leave prior to 2028. These Tier-1 firm power customers are paying $35.62 per megawatt hour (MWh) while the MidColumbia open market is currently averaging in the $20.00 per MWh range. Drafters also assert that BPA power has more value because it is firmed by power from the Columbia Generating Station (at a cost of nearly $50.00 per MWh) the one lone nuclear power plant in the Pacific Northwest. Firm power is only important when demand approaches supply. The Pacific Northwest is awash in power as exhibited by the low rates on the open market. The assertion that BPAs firm power is a better product than open market power is unsupportable. At one time, BPA was selling in the neighborhood of 200 million dollars of surplus power every year to California utilities. With the rapid development of renewable generation in California, that market has dried-up and surplus energy from California now travels north to the Pacific Northwest. Captive ratepayers are not a good indicator of power values the open market is a much better indicator.	This comment is inconsistent with the findings of the Draft EIS. The evaluation framework fairly characterizes the challenges of meeting load and resource variability in an environment with increasing integration of renewable generation on the grid. While this comment is correct in noting declining market prices, it conflates the reason for declining prices (increasing renewable integration) with ample power supply, without acknowledging the ability of that power supply to meet instantaneous demands. The evaluation framework of this EIS, which starts with the loss of load probability (LOLP), assesses the need for replacement resources, even if there are times of the year the region has a surplus of power. The seasonality of the power supply is important. The region often has surplus power in the spring when the weather is mild and flows are high. The LOLP analysis of Multiple Objective 3 showed that the region would have an annual risk of power shortages of around 14 percent stemming from shortages in the winter and summer. See Appendix J, Hydropower, Section 4.1.2.4 in the Draft EIS. The commenter suggests that all power products are the same and that a firm power sale is equivalent to a spot market purchase. This view is contrary to the findings in the EIS analysis. Bonneville supplies firm power to its long-term power customers. Firm power sold under these contracts is continuously available at all times, excepting events of force majeure. See Section 3.7.2.5, Bonneville Power and Transmission Customers in the draft EIS. Bonneville's firm power sales meet a customers load. This is demand that the customer can place on Bonneville (consistent with its contract) regardless of market supply or price. Spot prices reflect the price of power at specific points for specific amounts of power (i.e., 100 MW sold at Mid-C). Typically, these prices do not reflect the price of matching a customers changing load. The price and supply of power on the spot market can change dramatically depending upon weather conditions, natural gas prices, transmission, and generation availability. Significant changes in any of these variables can lead to supply scarcity and price spikes. For example, in February and March 2019, a cold snap increased spot prices in some hours to over $100/MWh. That is over three times Bonneville's Priority Firm (PF) rate. (Day-ahead sales of Heavy-Load-Hour Energy, meaning daytime and evening hours, peaked at about $900.) Nonetheless, Bonneville's long-term power sales customers received Firm Power at the stable PF rate. The cost of Bonneville's power includes significant benefits that would not be included with a purchase of energy from the open market. Specifically, Bonneville's average wholesale rate includes the cost of providing Federal power benefits to utilities with higher average system costs (approximately $250 million annually), transmission costs associated with delivering Federal power to loads served in other balancing authority areas (approximately $100 million annually), energy efficiency programs and incentives (approximately $125 million annually), support to utilities with low densities (approximately $40 million annually), and support to utilities with eligible irrigation loads (approximately $20 million annually).
6344	23	Nicholas Nelson	Idaho Rivers United	Page 3-803, Table 3-111 This table shows that nearly 50% of the annual generation from the lower four Snake River dams is sold as surplus energy while only 20% of the annual generation of Grand Coulee is sold as surplus.	The comment incorrectly interprets Table 3-111 in the Draft EIS as indicating the amount of surplus power sold by the respective dams. Table 3-111, indicates each dams relative contribution to the supply of surplus when measured against average generation above the critical water year level of generation as defined by the Bonneville ratemaking process. See Appendix H, Section 4.1. The table does not represent the actual commitment of each dam to sales of surplus because Bonneville does not sell power from specific projects, but from the pooled system. Power from this pooled system would only be sold as surplus once all other firm obligations have been met. Some of the power represented as secondary under average water conditions may still be needed to serve firm load obligations within the year as Bonneville's load obligations often exceed critical water output in certain seasons, months, or hours. Any remaining generation may be sold to meet other regional load or through other contractual agreements to Bonneville customers, depending on who purchases the power on the wholesale power market. These sales are then treated as a credit to the revenue requirement reducing costs to Bonneville preference customers. See Section 4.1.3.1 of Appendix H in the Draft EIS for additional details on how Bonneville evaluates secondary sales and revenue.
6344	24	Nicholas Nelson	Idaho Rivers United	Page 3-805, Table 3-112 This table shows costs and generation amounts from fiscal year 2015 five-year-old data that gives commenters little confidence on its relevance in FY2020 and beyond. For example, the cost of the Lower Snake Compensation Plan should be charged to the dams that are actually killing Idahos fish.	The data in Table 3-112 in the Draft EIS was from a recent, close-to-average water year as reported in the 2016 White Book, BPAs annual assessment of loads and resources that was current at the time the EIS was initiated. In the final EIS, this table is updated with the average generation from 80 historical water years. The amount of generation produced varies year-to-year based on the water supply, therefore generation for studies like the EIS is modeled using a set of many water years. While the cost of the Lower Snake River Compensation Plan (LSRCP) indeed stems from the operations of the four lower Snake River dams, Bonneville sells power from the lower Snake River dams as part of the unified Federal system, and the LSRCP is repaid by the sale of power to all of Bonneville's preference customers under its long-term contracts (see also Section 3.19 and Appendix Q).
6344	25	Nicholas Nelson	Idaho Rivers United	Page 3-820 Potential Resource-Replacement Portfolios assuming that replacement generation will be needed in the future with the retirement of unaffordable coal generation, drafters of this 19 document go on ad nauseum about the impacts of building carbon emitting generation. All forms of carbon generation are becoming obsolete even relatively low-cost natural gas generation. Commenters argue that the evolution toward low-cost, carbon-free generation is already underway. In March of 2019, Idaho Power agreed to pay $21.75/MWh for 120 MW of solar power in a 20-year power purchase agreement with Jackpot Holdings. The solar facility will offset a soon-to-close coal plant in Nevada starting in 2022. In September of 2019 the Los Angeles Department of Water and Power signed a 25-year contract for 400MW of solar for just below $20.00 per MWh backed-up with 300 MW of battery storage that can deliver 1,200 MWh to the grid during nighttime hours for $13.00 per MWh. The combined price for this project is $33.00 per MWh $2.62 less that the current BPA Tier-1 price. Finally, in February 2020, Tesla and California utility Pacific Gas & Electric received approval to install a massive 1 GWh battery storage project at PG&Es Moss Landing facility on the central California coast. This project is expected to be up and running by the end of 2020. The examples above show that cost effective, carbon-free generation and storage projects are a reality and quick to bring online.	Consistent with the comment, the EIS examined a conventional least-cost portfolio (natural gas) as a potential replacement for lost power generation, but stated that the region is not likely to construct new fossil-fuel based generation. The conventional least-cost portfolio serves as a lower-bound to the expected cost of replacement resources. See Section 3.7.3.1, Base Methodology, pages 3-820-21 in the draft EIS. The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. Given recent policy trends toward de-carbonization, the EIS considers a "zero-carbon" renewable resources portfolio. To avoid speculation for this renewable portfolio, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council in its 7th Power Plan (7th Power Plan page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, page 3-821 and Appendix H, Power and Transmission at Section 2.2. Storage technologies are considered a long-term resource of the 7th Power Plan, but have become more commercially available since the release of the 7th Power Plan. Storage is considered in the EIS and will likely now be considered a primary resource in the Councils 8th Power Plan. The EIS used resource costs from the 7th Power Plan and Mid-term updates, with the exception of batteries. To further address concerns about potential reductions in resource costs, consistent with the comment, publicly released draft information, such as updated prices for solar and battery storage, from development of the 8th Power Plan is included as rate sensitivities in the final EIS.
6344	26	Nicholas Nelson	Idaho Rivers United	Page 3-845 Effects on Power System Reliability In the narrative for the No Action Alternative and the other Multiple Objective Alternatives much is written about the possible effects of coal generation being retired including the specter of rolling blackouts in the region in two out of every three years. The reality is, coal generation is no longer price competitive and, like other unaffordable forms of power generation, will fade from the market while being replaced with other more affordable forms of power generation. This DEIS failed to do a full and transparent evaluation of all possible solutions and instead pivoted to the construction of high-cost natural gas and/or nuclear generation as the only solution for the retirement of coal generation. This kind of backward thinking will only exacerbate the dismal financial situation that BPA finds itself in.	Consistent with the comment, the EIS acknowledges that economics and regional policy are rapidly changing the energy landscape and affecting the viability of coal power generation, as seen through anticipated coal power plant retirements. However, despite the decreasing cost-effectiveness of these power plants, they are baseload power plants and removing them from the regional power system reduces system reliability. The EIS examined a range of potential renewable power generation resources to replace future retired coal power plants. The EIS did not evaluate natural gas or nuclear generation as replacements for the coal plants, contrary to the comment. See Section 3.7.3.1, Base Methodology, at page 3-820-21; and Appendix H, Section 2.3 Sensitivity of LOLP to Assumptions about Coal Capacity in the Draft EIS.
6344	27	Nicholas Nelson	Idaho Rivers United	Conclusions Throughout the Power and Transmission section of the DEIS the claim is often repeated that the four lower Snake River dams generate an average of 1,100 aMW per year while the actual records from 2004 through 2019 show the annual average to be 963aMW. The difference of 137aMW has a value that ranges from just over 24 million dollars at $20.00 per MWh (open market average) to nearly 43 million dollars at the current preferred rate of $35.62 per MWh. Given that the DEIS states that nearly 50% of the power generated by the lower four snake river dams is sold at surplus, commenters are confident in stating that the DEIS improperly overstated the power generation benefits of the lower Snake river dams by approximately 33.5 million dollars annually. The DEIS fails to account for the full cost of generating hydropower especially at the four lower Snake River dams. This has been an ongoing issue with the ACOE and BPA for many years. Commenters believe that an independent financial audit of the hydropower income and expenses should be conducted for each of the 14 dams identified in this DEIS.	The comment suggests that variability in hydropower generation and recent lower generation than historical averages leads to overstating power generation, and thus, the benefits of this generation, specifically at the four lower Snake River dams. Given this variability of hydropower generation the EIS uses 80 historical years of data to determine the average output of the Columbia River System hydropower projects. This robust analysis represents the full range of historical water years and hydropower generation and represents the highest quality information, not exclusively the most recent available data suggested in the comment. The profile of hydropower generation is described further in Appendix J and Appendix I. The 1,100 MW figure cited in the Draft EIS for Multiple Objective 3 (MO3) includes not only the loss in generation from the four lower Snake River dams, but also reduced generation from other measures in MO3, notably additional water withdrawals for irrigation, and increased juvenile fish passage spill at the lower Columbia River dams. The average generation from the four lower Snake River projects is about 1,000 aMW. Finally, the average annual value of the four lower Snake River dams for hydropower exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
6344	28	Nicholas Nelson	Idaho Rivers United	Comments on Transportation General Comments According to ACOE lock data, freight volume on the lower Snake River has been in decline for the past 20 years, a decline of approximately 60% from its peak in 1998 (from 9 million ton miles to just under 3 million ton miles). Of the 14 ACOE administered U.S. Inland Waterways, the lower Snake ranks dead last in freight volume. By contrast, the Columbia River ranks eighth at 2.1 billion ton miles. Leading the list is the Mississippi River at nearly 160 billion ton miles. The primary factor in the drop of navigation on the lower Snake River is market driven. Farmers and co-ops have been moving from barge to rail transportation due to economic and logistical reasons. The construction of four railroad unit loader facilities on the Palouse provides the efficient loading of 110 car grain trains that then can ship to a variety of destinations instead of the single barge alternative that terminates in Portland OR.	Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS shows. It is true that barge movements on the Snake/Columbia river have declined somewhat over the past 20 years, but the decline has stabilized over the past 10 years. That decline is mostly attributed to investments in shuttle rail terminals. The EIS utilizes the most recent 10-year average as a basis for its forecast volume of freight that would transit on the lower Snake River. While it is true that the Snake River freight volume is certainly smaller than the volume of the Mississippi and Ohio River systems, it is nonetheless an important transportation option for a large volume of freight, particularly for farm products, with the Columbia-Snake River system serving as one of the largest exporters of farm products in the U.S., and the largest exporter of wheat. The co-lead agencies' analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term.
6344	29	Nicholas Nelson	Idaho Rivers United	Specific comments i) Page 3-1059, Line 31728 - Commenters disagree with the blanket assertion that barges are the most fuel efficient means of transportation. While both rail and barge are much more efficient that trucks, not all waterways are the same. River flows and weather conditions affect the efficiency of barging whereas the small frontal cross section of rail makes it less susceptible to the high winds associated with the Columbia and	On a ton-mile basis, on the river, barges are consistently more efficient than other transportation modes. The FEIS states that truck transportation can emit nearly 10 times more CO2 per ton-mile than inland barges, citing Kruse, Warner, and Olson 2017 in section 3.10 and referring to Section 3.8, Air Quality and 32426 Greenhouse Gas Emissions for additional details. As such, reductions in navigation service that result in transportation of goods via land-based modes are assumed to generally

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Snake rivers and rail doesnt have to contend with river currents. The DEIS cites no studies conducted on the differences between the efficiencies of rail and barging on the Columbia and Snake rivers.	result in increased air pollutant emissions. It is true that longer truck movement can be necessary to access the waterways than rail movements, hence movements by truck-barge can require more energy than rail-only movements in some cases. The analysis done for MO3 analyzed the cost difference of moving grain without the lower Snake River dams. The cost to move grain from their origin to the lower Columbia River ports for export was more expensive without the barging option.
6344	30	Nicholas Nelson	Idaho Rivers United	ii) Page 3-1060 - The narrative on the possible return of container shipping returning to the lower Snake river is speculation.	The paragraph cited by the commenter does not state that container shipping will return to the lower Snake River; it states that container shipping is returning to the Port of Portland and recognizes that this option is possible.
6344	31	Nicholas Nelson	Idaho Rivers United	iii) Page 3-1061, Line 31790 - The DEIS states that However,within the past four years, total downriver shipments have somewhat rebounded. and then goes on to cite an increase of .1 million ton miles between 2015 and 2018. This is simply cherry-picking data to put a positive spin on the 20-year decline of barge shipping.	Access to barge transportation is the most cost effective means of accessing export markets for the many grain producers in the Pacific Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS shows. It is true however, that barge movements on the Snake/Columbia river have declined over the past 20 years, but it also appears that the decline has stabilized over the past 10 years. The text of the EIS has been updated to remove the "rebounded" characterization and to describe how downriver shipment volumes have stabilized in recent years.
6344	32	Nicholas Nelson	Idaho Rivers United	iv) Page 3-1061, Fuel and Other Petroleum Products - This section is confusing and makes conflicting statements. The take-home message is that the great majority of upstream fuel and petroleum shipments terminate near Pasco WA and there is infrequent transport upstream on the lower Snake River above Ice Harbor Dam.	The commenter is correct. This was unclear in some instances in the Draft EIS, and has been corrected and clarified in Section 3.10 and Appendix L in the Final EIS.
6344	33	Nicholas Nelson	Idaho Rivers United	iv) Page 3-1061, Oversized Objects - This entire section should be removed. In 2017 a permanent settlement was signed by the U.S. Forest Service, the Nez Perce Tribe, and Idaho Rivers United. This agreement blocks the transport of what are commonly called mega-loads across U.S. highway 12 within the Nez Perce - Clearwater National Forest.	A clarification has been added to the section that describes oversized loads in Section 3.10.3.5 to address this settlement.
6344	34	Nicholas Nelson	Idaho Rivers United	v) Page 3-1117, Line 33025 - This section is intentionally misleading. Virtually all upbound fuel and petroleum products terminate on the McNary pool a short distance above the confluence of the Columbia and Snake rivers. This location is below Ice Harbor Dam and breaching would have little to no effect on those deliveries. While the fuel depot is located on the Snake River a short distance upstream from the confluence with the Columbia River, it may be technically 22 correct to state that Fuel comprises 27 percent of the overall tonnage on the lower Snake River. It is dishonest to imply that the fuel then moves upstream through the lower Snake River dams.	The commenter is correct that this was unclear in some instances in the Draft EIS, but was not intentionally misleading. This has been corrected and clarified in Section 3.10 and Appendix L in the Final EIS.
6344	35	Nicholas Nelson	Idaho Rivers United	vi) Page 3-1117, Line 33037 - The transportation modeling is flawed as it assumes that lower Snake River dam breaching would preclude the use of existing shipping facilities and that cargo would be shifted to trucks. Again, this is a flimsy attempt to prop-up the continuation of the status quo. All of the grain loading operations located on the lower Snake River are adjacent to rail lines and could be converted to loading rail cars instead of barges. Indeed, the Port of Wilma added a rail spur for just that purpose. Equally flawed are the assumptions that, without barging, the railroads may raise rates from 20% to 50% - once again fear mongering on the part of the DEIS. There are plenty of avenues to deal with predatory pricing without the American taxpayer on the hook to maintain a navigation system to serve as a price control mechanism. If the barging and agricultural community believes that the navigation system is so valuable, they should assume the entire cost of operating and maintaining the system. Finally, missing from this analysis are the possible benefits of being able to move products to markets that are unavailable to barging customers.	It is difficult to know exactly what decisions would be made by public and private entities regarding transportation infrastructure investment under a dam-breach scenario. Research completed for the EIS, including input from local shipping operators, indicated that certain elevator-to-river port movements via short-line rail are not currently available. Shippers would need to operate on part of Union Pacific's rail line, and WATCO's operating agreement with Union Pacific does not allow for these movements. This assumption is maintained for the MO3 alternative; however, it is true that if under a dam breach scenario movements on short lines rails were allowed, it would somewhat reduce the anticipated shipping cost increases. A statement has been added to the EIS in section 3.10.3.5 to describe this effect, along with additional discussion in Appendix L on how the assumptions surrounding transportation infrastructure and movements effect shipping costs.
6344	36	Nicholas Nelson	Idaho Rivers United	vii) Page 3-1131, Commercial Cruise line Operations - The benefits of the cruise line operations to the local and regional communities are overstated. The operators are national or international companies and much of their revenue leaves the area. Additionally, cruise ship passengers sleep and dine aboard ship and their time in port is limited - as is the amount of money they spend locally. As Clarkston WA is the terminus of the operation, departing passengers are transported to the airport in Spokane WA and new passengers are then transported back to Clarkston to begin their cruise downstream to Portland OR. While commenters recognize that there are some local benefits from the cruise industry, we believe that those benefits are less than the DEIS assumes.	Cruise ship visitation is characterized in Section 3.10 Navigation. Section 3.10.3.5 describes the contribution of cruise ships as providing demand for approximately 230 jobs in the region, which would include employment in the industry itself as well as increased demand for services at ports of call. The EIS does not claim that business closures would result from changes in the navigation channel access under MO3. The commenter is correct that some of the costs of each trip taken by cruise ship passengers would accrue as revenues to national companies, but the calculated regional economic effects are associated with daily passenger expenditures on their expeditions rather than on ticket prices.
6344	37	Nicholas Nelson	Idaho Rivers United	Conclusion The DEIS narrative on transportation greatly exaggerates the benefits and downplays the negatives of maintaining the status quo on the lower Snake River from Lewiston ID to its 23 confluence with the Columbia River at Pasco WA. Meanwhile, the American taxpayers are subsidizing the expense of these dams and the navigation system at an ever increasing rate as the system continues to age.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations.
6344	38	Nicholas Nelson	Idaho Rivers United	Comments on Recreation Free-flowing rivers are not just lifelines for fish, wildlife and people. They are havens for a wide range of recreational pursuits: fishing, bird watching, hiking, hunting, rafting, camping and jet boating. Whats more, these activities translate directly into economic activity for riverside communities and businesses. In the years before the lower Snake River was stilled by dams, people congregated on its beaches, fished from riverbanks, and camped and hunted in the river bottom. They rafted more than 50 rapids that once surged at up to 180,000 cubic feet per second through the remote, arid canyon--rapids with names like Log Cabin, Little Pine Tree and Haunted House. When all four dams on the lower Snake River were completed in 1975, all the free-flowing, river-related recreational benefits were gone and replaced with big, silent reservoirs with sterile shorelines. What was once a canyon where people floated, hiked, camped and hunted was transformed into a deserted place where few ever bother to go. What was once a booming recreation economy in towns like Lewiston, Clarkston, Riggins, Salmon and Stanley was transformed into a taxpayer-subsidized system of dams and locks of littleand decreasing interest even to the farmers who use it. In the final draft of its 2002 study on breaching the four lower Snake River dams, the U.S. Army Corps of Engineers assigned to a dam breaching scenario a net recreation benefit of $71 million per year. This grossly understated estimate lower than the Corps own contractors determined was called into question even as the study was published. Still even this gross misrepresentation was minor when compared to the complete ignorance the agencies gave this economy in the current DEIS. As noted in a December 2000 Washington Post series examining corrupt benefit-cost analyses performed by the Corps, the very economists hired for the study had actually estimated 24 recreation benefits would range from $82 million to $509 million a year, with a midpoint of $196 million per year. In 2006, the Outdoor Industry Association published the first comprehensive valuation of outdoor recreation in the U.S. According to its estimate, this sector of the economy is worth $646 billion annually. Western States disproportional share of the total is $256 billion annually, generating $31 billion in taxes and directly employing 2.3 million people. Other regional and local analyses have followed. The National Park Service estimates nonmotorized boating in the Grand Canyon generates $83 million annually and nearly 600 jobs. In 2007 according to the Colorado guides and packers association, river rafting in that state was worth $153 million. In the same year, fishing, jet boating, kayaking and rafting on the remote, 34-mile wilderness segment of the Rogue River in Oregon was worth $30 million. None of these numbers cited above consider the enormous economic impact a restored salmon and steelhead fishery would have on the Snake River and communities upstream in Idaho and eastern Oregon. In 2001, the Idaho Department of Fish and Game calculated the direct spending benefit of its constituents who bought salmon and steelhead tags in a rare year of decent salmon returns to the state: $46 million, with $10 million of that in the rural riverside town of Riggins alone. Other studies place the figures higher still. An April 2003 study by Boise-based Ben Johnson Associates, Inc. places direct and indirect angler spending in Idaho during the 2001 fishing season at $89.9 million. The same economic think tank did a follow-up report11 in 2005 to estimate the potential economic impact of restored salmon and steelhead runs throughout Idaho and determined direct and indirect angler spending could generate $544 million annually. By contrast, the 1999 Corps report valued general recreation on a free-flowing Snake at a paltry $5.9 million to $31 million. Improved fishing, both in the Snake and its hundreds of miles of wilderness tributaries, was to be worth a maximum of $4.5 million. In 2015, Tacoma, Washington-based Earth Economics conducted a review12 of the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report / Environmental Impact Statement 25 (Section 13-49 through 13-81 of the Economic Appendix I - Recreational Benefits of Breaching the Four Lower Snake River Dams). The conclusion of the Earth Economics review was that a free-flowing lower Snake River would have an annual recreational value of $1.537 billion. The fact that this DEIS doesnt even provide an accounting for a recreation economy, even though they were able to provide accounting in previous DEIS and BiOps, is arbitrary and capricious, and further proves the inherent bias the agencies had in preparing their analysis and recommendations.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The types of activities and values assessed in the Earth Economics report are evaluated within the CRSO EIS. However, the framework and management scenarios described in the Earth Economics report are not directly comparable to the No Action and action Alternatives evaluated in the CRSO EIS.
6344	39	Nicholas Nelson	Idaho Rivers United	Comments on Climate Change It is indisputable that future climate conditions are expected to be warmer and more variable, and there is strong empirical evidence that ocean conditions will largely follow suit. However, the agencies failed to analyze whether any of the alternatives would benefit salmon in a changing, warming world. Again, this was not an egregious oversight or an area without enough data, but is purposefully omitted, because this would not support the Preferred Alternative. In fact, not only would it support MO3 (dam breaching) as the most effective alternative to create climate resilience, but would have also shown that the PA will be even more likely to lead to the extinction of anadromous fish in these scenarios. The agencies must analyze how the alternatives will perform in light of reasonable and available information about climate impacts over different periods of time. For example, the agencies analysis could include a minimal, moderate, and high warming scenario over a 30, 50, and 100 year period. This discussion should include an explanation of the effects on anadromous fish and other resources that is sufficiently detailed to allow a meaningful evaluation of the results of the alternatives in a climate change world. The agencies also must analyze the likelihood that each alternative will lead to recovery in a broad sense in the real world, i.e., in a warming world. Currently the agencies have only considered whether the alternatives will improve conditions for salmon against the baseline of the no action alternative without consideration of climate change and without acknowledging that the no	The technical and policy elements of this Draft EIS are in full compliance with binding USACE policy and guidance for qualitative assessment of climate threats and their plausible effects and impacts. The primary controlling policy and guidance are the USACE Climate Adaptation Policy Statement, signed by the Assistant Secretary of the Army for Civil Works in 2011, updated and signed again in 2013, and remains in force now; and USACE Engineering and Construction Bulletin 2018-14, "Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Projects." The numerical-model simulated outputs were evaluated by multiple technical means (see record of the full USACE Agency Technical Review), and were tested using the set of analytical measures created by the USACE Climate Preparedness and Resilience program to ensure that sound science and engineering compliance with USACE climate change policy and guidance. Those analytical tests are described in ECB 2018-14 (listed just above) and in USACE Engineer Technical Letter 1100-2-3, "Guidance for Detection of Nonstationarities in Annual Maximum Discharges." The assessment of climate threats and impacts is qualitative only in the sense that the biological and other impacts models did not directly ingest the physical hydroclimatology outputs modeled for the assessment. Those hydroclimatology outputs are fully quantitative and so can be the basis for refined estimates of effects and impacts should those be required following this Draft EIS. The co-lead agencies agree that climate change may impact hydrology, water temperatures, flood risk management operations. That is why the agencies used the best available information, from on-going regional climate change studies and work, to investigate climate change impacts on CRS operations. The co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Water resource management, through storage and regulation may be increasingly important. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				action alternative itself is illegal. and has failed to achieve significant population rebuilding or recovery for any species. Indeed, even with 26 twenty years of effort pursuing the approach of the no action alternative, salmon and steelhead populations remain at dangerously low levels.	climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4).
6344	40	Nicholas Nelson	Idaho Rivers United	If the agencies had incorporated the effects of climate into their analysis of the alternatives, it would have shown that the no action alternative, MO1, MO2 and the preferred alternative will be even more likely to lead to the rapid extinction of many runs. A minor improvement that merely slows the rate of a baseline of decline towards extinction cannot meet the various statutory requirements the agencies must meet. The Fish Passage Center analysis of SARs under each alternative does not incorporate climate, because it is based on the Comparative Survival Study (CSS) model that uses historical data. However, the model produces a range of likely SAR returns. Experts agree that it is reasonable to assume that SARs will be at the low end of the range predicted by the CSS model with the additional adverse effects of a warming world but because the DEIS does not present these probabilities at all or employ them in its analysis of effects their analysis lacks vital and relevant information.	The Draft EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives effects on salmon and steelhead, so temperature effects to survival have been incorporated into the overall analyses of each alternative. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at the resolution (river-scale vs. global or regional) required at this time. Therefore it was not possible to reliably model water temperature changes under climate change for incorporation to either of the fish models. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature and anadromous fish in Section 4.2.3. As noted by the ISAB in their review of the CSS model results generated for this EIS (ISAB 2020-1), changing climate conditions should be carefully assessed when considering potential impacts to salmon and steelhead, but the co-lead agencies note the concerns raised by the ISAB regarding the CSS's quartile range analysis and the likelihood or probabilities of SARs falling below 1 percent.. The co-lead agencies will evaluate that analysis as it evolves but are not relying on the probability analysis at this time.
6344	41	Nicholas Nelson	Idaho Rivers United	If the agencies had incorporated the effects of climate into their analysis of the alternatives, it would have shown that the no action alternative, MO1, MO2 and the preferred alternative will be even more likely to lead to the rapid extinction of many runs. A minor improvement that merely slows the rate of a baseline of decline towards extinction cannot meet the various statutory requirements the agencies must meet. The Fish Passage Center analysis of SARs under each alternative does not incorporate climate, because it is based on the Comparative Survival Study (CSS) model that uses historical data. However, the model produces a range of likely SAR returns. Experts agree that it is reasonable to assume that SARs will be at the low end of the range predicted by the CSS model with the additional adverse effects of a warming world but because the DEIS does not present these probabilities at all or employ them in its analysis of effects their analysis lacks vital and relevant information.	The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change at the appropriate resolution (river-scale vs. regional- or global-scale) and, unfortunately, they have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. Therefore it was not possible to reliably model water temperature changes under climate change for incorporation to either of the fish models. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature and anadromous fish. These analyses are documented in Section 4.2.3 for the MO Alternatives and Section 7.8.4 for the Preferred Alternative. Overall, the Preferred Alternative is expected to result in benefits to anadromous salmon and steelhead. The analysis in Section 7.8.4 recognizes that some of the benefits to fish from the Preferred Alternative could be offset by the effects of climate change. As noted by the Independent Scientific Advisory Board (ISAB) in their review of the CSS model results generated for this EIS (ISAB 2020-1), changing climate conditions should be carefully assessed when considering potential impacts to salmon and steelhead, but the co-lead agencies note the concerns raised by the ISAB regarding the CSS's use of quartile range analysis and the likelihood or probabilities of SARs falling below 1 percent. The co-lead agencies would evaluate that analysis as it evolves, but are not relying on the probability analysis at this time.
6347	2	chrismurray92@gmail.com	N/A	In addition to the direct impact of the dams on the habitat of the salmon, we also need to look at the impact to the native tribes in the Pacific Northwest	The impact of the Columbia River System on Native American tribes and tribal culture is acknowledged in the Executive Summary and discussed at key points throughout the EIS, including Sections 3.16 and 3.17. For a full discussion on how tribal concerns and input were incorporated into the process, see Section 9.3, which describes this process in detail.
6355	1	y.demissie@wsu.edu	N/A	1) Continuing the study by involving both the proponent and opposing groups of the dams directly (or beyond providing suggestion at the early stage of the study and comments on the draft report) 2) Seeking for more independent scientific analysis and recommendations. The co-leading agencies have direct involvement in managing and operating the dams, making the current findings and the recommendations from the study questionable. The study layout an excellent foundation for more scientific inquiries and optimization of the system to meet the multiple objectives.	The co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as cooperating agencies, and over 30 of those invited agreed to participate. Staff from the Cooperating Agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation, maintenance and configuration of the dams in the CRS system. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The draft EIS was subjected to two internal agency reviews by the Corps of Engineers experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available. The co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions on achieving broader recovery objectives. The Preferred Alternative for long-term system operations, maintenance and configuration of the CRS presented in the Draft EIS is based on todays conditions and environment. Its also important to note that technology is quickly changing, as is the regions dynamic environment and energy market, and the region needs to consider new information and adaptively manage resources.
6355	2	y.demissie@wsu.edu	N/A	3) Addressing the uncertainty and assumptions in the analysis. The report highlights the presence of various sources of uncertainties (e.g., model uncertainty, the future projection of climate, socioeconomic activities). Because of the uncertainty in simulating the latent mortality, the preferred alternative can be worse than the no-action alternative for the fishes. The uncertainty needs to be addressed and accounted for by using state-of-the-art stochastic modeling approaches so that the public will have better quantitative information on the various alternatives.	In terms of effects on salmon and steelhead, the CSS and NMFS COMPASS and Lifecycle models predict different outcomes, depending on assumptions used for decreased latent mortality. To address the uncertainty due to the different model results, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, and TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
6364	1	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	Prior to discussing the Tribe's concerns, the Tribe would like to express its disappointment in the government-to-government consultation conducted by your agencies in this matter. First, it was made clear to the Tribe that consultation would occur with the Tribe prior to release of the EIS despite the fact that the Tribe is not a cooperating agency. We were very clearly told that our status would not penalize us in the process. This was not the case.	Thank you for your comment. The co-lead agencies remain willing to discuss the EIS during government-to-government consultation prior to signing the Record of Decision.
6364	2	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	Second, the Tribe requested an opportunity to meet with the agencies to discuss our proposal for a Supplement EIS (discussed below) in January 2019. A meeting to discuss this proposal did not occur until March 2020, more than a year after our initial request and after the release of the EIS. Both these actions send a powerful message about your agencies' intentions about consultation with the Tribe. Accordingly, the Tribe would like to request formal government-to-government consultation once your agencies have crafted changes to the EIS to discuss those changes, how your agencies have addressed the Tribe's concerns, and the process in finalizing the document.	Consultation with the Coeur d'Alene Tribe (CDA) concerning the CRSO EIS is important to the co-lead agencies. We apologize that the time schedule for release of the Preferred Alternative and the Administrative Draft EIS was negatively impacted due to the complexity of the document and the ongoing work with the co-lead agencies. We could not have the substantive consultation with the CDA until those documents were done. As such, we did accomplish a government-to-government consultation with CDA on March 10, 2020, as soon as those documents were finished. Additionally, the co-lead agencies have been engaging regularly with the nineteen impacted Tribes and will continue to do so. For a further description of Tribal engagement, please see the consultation and 3-tiered engagement process discussed in the Executive Summary and the Tribal Perspectives Section of 3.17 and discussion of Tribal consultation in Sections 1.5, 3.5, 3.15 and Chapter 9.
6364	3	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	The Tribe also reiterates its earlier request that the comment period for the EIS be extended.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
6364	4	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	It should be noted that these comments and the previously submitted comments are submitted as part of the NEPA process and do not, in any way, replace or diminish the agencies' obligations to consult with the Tribe on a government-to-government basis or the agencies' trust obligations to protect tribal people and resources.	The co-lead agencies have stated vigorously throughout the CRSO process that impacted Tribes can request government to government consultation at any time. For a further description of Tribal engagement, please see the consultation and 3-tiered engagement process discussed in the Executive Summary and the Tribal Perspectives Section of 3.17 and discussion of Tribal consultation in Sections 1.5, 3.5, 3.15 and Chapter 9.
6364	5	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	As discussed below, the Tribe is extremely disappointed that the agencies have failed to meet its NEPA and trust obligations to consider fish passage in the Upper Columbia (above Chief Joseph and Grand Coulee Dams) in the EIS. Over and over again, the Tribe and other tribes have requested that fish passage be considered. Despite this, the matter was brushed aside with nearly no mention in the EIS. As discussed below, NEPA requires a range of alternatives be developed to evaluate the myriad of impacts the CRSO have had on the environment. We appreciate that the agencies looked at alternatives that met multiple objectives. However, based on these alternatives, it is still apparent that the agencies' goal from the onset was to follow the letter of NEPA, but not the intent, to justify maintaining systems operations in as close to a "status quo" manner as possible.	Measures to reintroduce salmon above CHJ and GCL were evaluated early in the alternative development process but eliminated from further consideration. Details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. It was not feasible to proceed with a detailed consideration of reintroduction in this EIS. Given the importance, complexity, and large-scale of reintroduction, a coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary and is currently underway. Defining reintroduction objectives requires a decision-making framework and a series of regional workshops just to approach the first step. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020, when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
6364	6	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	Moreover, as discussed in our earlier letter and below, the 45-day comment period to review thousands of pages of EIS during the midst of the COVID-19 crisis is unacceptable. We reiterate our request for an extension of the comment period.	See response to Comment 6364-3.
6364	7	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	Based upon our review, the Tribe has the following comments on the EIS: 1. BACKGROUND In the Coeur d'Alene Tribe language, we are called Schitsu'umsh, meaning "those that were found here." This name was derived from the Tribe's world view that the creator had placed the people around the lakes and water ways of the region to live and prosper in harmony with the natural resources. The original homeland included some five million acres, stretching from Montana in the east to the Spokane River Valley, in what is now Washington State, from near the Canadian border to the confluence of the Snake and Clearwater Rivers in North Idaho. Tribal traditions include a deep respect and reverence for natural law, which today creates a powerful voice for responsible environmental stewardship. Since time immemorial, the Schitsu'umsh engaged in the annual cycles, shaped, in no small way, by the salmon that migrated within their homeland. Salmon runs were historically evident in the Spokane River and Hangman Creek watersheds. Tribal members shared harvest with other tribes along the Spokane River, Columbia River (Kettle Falls to Celilo Falls), and in the Clearwater River in the southern-most part of their homeland. Conservative estimates placed the historic harvest at approximately 1.3 million to 2.3 million pounds of salmon and steelhead annually with fish consumption as high as 1,000 pounds per year per person (which includes resident fish consumption). All drainages relied upon by the Tribe for anadromous fish harvest have been adversely impacted by dam construction and operation. Chief Joseph and Grand Coulee dams block access for anadromous salmon and steelhead to significant amounts of habitat, totaling 711 miles for spring Chinook and 1,610 miles for summer steelhead for spawning, rearing and migration. Much of these habitats fall within the Coeur d'Alene Tribe's usual and accustomed fishing areas. In addition, construction of Dworshak Dam eliminated 54 miles of riverine habitat and blocked access to a much greater, but unquantified amount of habitat on the North Fork of the Clearwater River, which accounted for sixty percent of the average amrnal count of steelhead which passed into Idaho via the Snake River. The loss of these habitats to anadromous fisheries has had a significant and continuing impact on Coeur d'Alene Tribal cultural, economic and social wellbeing. The construction of the federal hydropower system and subsequent system operations, extinguished all the stocks of salmon that supported the Tribe. It is a paradox that endangered species are both a tragic consequence of the CRSO, and a luxury that the Tribe is not afforded. The construction of Grand Coulee Dam and the later construction of Dworshak Dam prevent salmon from returning to our usual and accustomed fishing grounds and deprived the people of the opportunity to exercise their cultural, subsistence and ceremonial practices of their ancestors. This loss of anadromous fish has in turn created a heavier reliance on the harvest of resident fish and wildlife populations by the Coeur d'Alene Tribe and intensified food security issues related to traditional subsistence practices.	The information provided in this comment is substantially similar to the information that that Coeur d'Alene Tribe provided which is included in the Tribal Perspectives Section 3.17.

6364	8	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	3. ISSUES OF SIGNIFICANT CONCERN a. Inadequate Public Comment Period: A comment period of 45-days during the midst of the most serious pandemic in modern times is unacceptable. As a result, this process has failed this capture the Tribe's intent to be heard on critical issues that impact their culture. Given the enormity of the document by volume and the complexity by issue, as well as the current lockdown that affects normal operations, the Tribe requests an extension of the comments period by another 60 days in order to make well considered comments that may ultimately impact the Tribe in the future. The decision to not extend the comment period was made before the formal extension requests were made. The Coeur d'Alene Tribe was told this during a government-to-government consultation meeting in Spokane on March 10, 2020. The Tribe is disappointed that the co-Lead agencies continue to discard the Tribe's input on critical procedural and contextual topics.	See response to Comment 6364-3.
6364	9	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	Failure to Consider Fish Passage: The Tribe once again reiterates its position that fish passage in the Upper Columbia River (above Chief Joseph and Grand Coulee Dams) must be addressed in this NEPA process. Unfortunately, the agencies have failed to honor its tribal trust obligations, its obligations under NEPA, and the calls of communities across the Northwest to analyze Upper Columbia fish passage options in this document. Over the last decade the Tribe has participated in two major forums dealing with the Columbia River (the Columbia River Treaty ("CRT") with Canada and over the last three years the CRSO EIS process). In both of these processes we believed that our voice would be heard and critical issues to the Tribe would be addressed in an atmosphere of professional respect. The Tribe has worked tirelessly within the CRT process to elevate fish passage as an issue that needed to be addressed. We were told by your agencies that this process would not provide the Tribes an equal seat in the negotiation process and that fish passage was also something outside the scope of the CRT. They said, "there are other processes to deal with fish passage."	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 with the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
6364	10	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	The Tribe then looked to the CRSO EIS process as a means to address fish passage. The Tribe heard all the excuses for not dealing with fish passage in the CRT and then had to witness these same agencies begin to distance themselves from any mention of conducting a detailed evaluation of dam removal or the impacts of the dams on fish passage for a new set of reasons (fish passage is too complex and would take too long, given the President's mandated accelerated timeline to complete the EIS). Although during the scoping phase of the process there were hundreds of comments requesting fish passage be fully vetted in the CRSO process, it immediately became evident that fish passage was not going to be addressed.	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
6364	11	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	In 2018, Dave Mabe of the Bureau of Reclamation ("BOR") could not have made it more clear to the tribes: "fish passage was not even on our radar." This was insulting, given the vast amounts of work the tribes have done to evaluate passage above the blocked area. See February 7, 2017 letter from Chairman Allan. As the Tribe's only access to salmon is by trucking surplus hatchery fish in the unblocked areas to the reservation, it is critical that the Tribe's voice be heard in the only process presented to them. In January 2019, at a meeting with tribes at Northern Quest Casino, the agencies indicated that looking at fish passage "would take too much time," was, "too complicated," and that they "did not have the information to analyze passage." These statements are all without merit. First, there is no exception in NEPA from analyzing alternatives because it would be "too hard" to do so. Second, ample information has existed for some time about fish passage options and much of this information has been provided to the agencies in this process and other processes, including most recently the Fish Passage and Reintroduction Phase I Report. 1 The Phase I Report confirms the reintroduction of salmon to the Upper Columbia River is likely to achieve identified tribal goals given the following: Current dam operations; Existing riverine and reservoir habitat conditions; Donor stock availability and risks to resident fish species; The likely effectiveness of state-of-the-art juvenile and adult passage; and technologies that could be built at both Chief Joseph Dam and Grand Coulee Dam. Results from these investigations have shown that reintroduction is viable for the species evaluated. Unfortunately, this information is not reflected in the EIS and the co-Lead agencies appear to have selectively ignored this extensive body of literature. Other information has been available to inform the analysis of fish passage and reintroduction as an alternative in this EIS. These studies include: 2018 Draft Technical Memo: Sockeye Salmon spawner abundance potential estimates in the Sanpoil River. Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 with the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
6364	12	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	The Tribe believes that the Agencies have an obligation under NEPA to consider all reasonable alternatives, including passage. This is well reflected in Judge Simon's May 4, 2016 opinion that states, "One of the benefits of a NEPA analysis, which required that all reasonable alternatives be analyzed, is that it allows innovative solutions to be considered and may finally be able to break through any bureaucratic logjam that maintains the status quo." The Tribe believes that the failure to consider an alternative with Upper Columbia fish passage violates NEPA by failing to consider reasonable alternatives. Not a single alternative considered in the EIS considered or analyzed this option. Failure to take a hard look at these alternatives is unlawful. An EIS must include a robust analysis of alternatives to the proposed action: this discussion is "the heart of the [EIS]" and must "provid[e] a clear basis for choice among options." 40 C.F.R. 1502.14.	The Co-Lead Agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. Measures to reintroduce salmon above CHJ and GCL were evaluated early in the alternative development process but eliminated from further consideration. Details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. It was not feasible to proceed with a detailed consideration of reintroduction in this EIS. Given the importance, complexity, and large-scale of reintroduction, a coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary and is currently underway. Defining reintroduction objectives requires a decision-making framework and a series of regional workshops just to approach the first step. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020, when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
6364	13	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	The Tribe understands the NEPA process and believes the letter of the law can be read as "Purpose and Need for Action" and understands the complexity in developing pragmatic and legally defensible alternatives. We appreciate that the agencies looked at alternatives that met multiple objectives, however based on these alternatives, we still believe that the agencies goal from the onset was to follow the letter of NEPA, but not the intent, to justify maintaining systems operations in as close to a "status quo" manner as possible. The failure of the EIS to consider fish passage also amounts to a significant violation of the agencies' trust responsibility to the Tribe. In essence, the agencies have failed to consider and address the impact of the CRSO on tribal health and welfare. This remains the culmination in spite of our many declarations of such. This failure, however, reaches beyond impacts just to the Coeur d'Alene Tribe. This pandemic continues to show us the frailty of our food and commodities streams, our economic markets and our lack of resources within the country to protect our national interests. The Columbia River ecosystem has been abused for over 170 years and now, as we contemplate the next fifty years of project operations, we have the ability to react to changing global environmental conditions and attitudes and embrace the bounty an intact Columbia River ecosystem can provide. From a regional and local food security perspective, no more evidence is needed to stop the current path the CRSO process is taking and re-evaluate the benefits of returning fish above the blocked area.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives) as well as meet the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is most likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 with the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6364	14	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	c. Fish Management Initiative and Supplemental EIS: The agencies have determined it inappropriate to include fish passage above the Grand Coulee and Chief Joseph Dams into the EIS evaluation. Instead, they have proposed to create a new process in which to address this most critical issue related to the CRSO process. As outlined in various sections of this document this, "new" process greatly concerns the Tribe because there are no details defining what this process would be, how it would function, and how would it provide legally binding mandates that require fish passage. For example, Chapter 2-79 outlines a, "decision making framework" that would be necessary to just approach the first step of defining reintroduction objectives." Yet the Tribe has questions of concern that include, but are not limited to: 1) what entity that is currently not at the table is missing from this new group (i.e., why do we need a new group); 2) how will the outcomes and decisions made by this new initiative be legally binding; 3) what would be the timeline for the completion of this process; 4) who will fund this effort; and 5) how would the outcomes of this new initiative be incorporated into the decisions rendered in the CRSO process, or any other legally binding processes and agreements? It is one thing to discard our repeated requests to include fish passage into the current EIS, but to cast this issue into a nebulous forum without defining any specifics of how it will function, or influence future decision making, is unacceptable. The Coeur d'Alene Tribe requests that far more detail be written into the EIS that provides the answers to these questions. Without details of this new process, we remain skeptical and believe it will lead to the creation of a process that will be nothing more than a continuation of delays to address this issue.	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the co-lead agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
6364	15	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	The Tribe believes that the final EIS should establish and identify the tasks of the FMI, including identifying a fish passage alternative for later analysis and gathering of relevant data to support such an analysis. The final EIS must identify members and funding for the FMI. Second, the EIS/ROD should establish a time frame for the development of a passage alternative by the FMI. Lastly, the final EIS should commit to the development of a SEIS that provides an analysis of the FMI fish passage alternative (or an alternative fish passage proposal if the FMI fails to develop proposal). As soon as the Tribe was told the draft alternatives would not address fish passage, the Tribe requested that the co-Lead agencies consider doing a supplemental EIS that only focuses on the issue of fish passage. We believed that this was a viable solution wherein the co-Lead agencies would meet their EIS completion deadline and the essential obligation under NEPA could also be fulfilled. The Tribe also believes that this approach is well-founded in the legal obligations of the Agencies. NEPA regulations, 40 C.F.R. 1502.9(c), provides that agencies must prepare a supplement to an EIS if there are significant new circumstances or information relevant to environmental concerns and bearing on the proposed action or its impacts. The regulations also provide that an agency should prepare a supplemental EIS if it determines that doing so will further the purposes of NEPA. Since providing that feedback, the Tribe has heard that a supplemental EIS dealing specifically with fish passage was not being considered by the action agencies. The Tribe is against creating a new process without any legally binding requirements that the work of that group will actually occur, be funded, or be thoroughly analyzed in a NEPA process. Of all the comments we have provided, this should be considered a top priority.	Measures to reintroduce salmon above CHJ and GCL were evaluated early in the alternative development process but eliminated from further consideration. Details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. It was not feasible to proceed with a detailed consideration of reintroduction in this EIS. Given the importance, complexity, and large-scale of reintroduction, a coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary and is currently underway. Defining reintroduction objectives requires a decision-making framework and a series of regional workshops just to approach the first step. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020, when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
6364	16	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	d. Failure to Analyze Impacts to Tribal Health and Economies: In previous NEPA processes, the agencies have hired experts agreed upon by impacted tribes to assess and document the impacts in a detailed manner. The report titled Tribal Circumstances & Impacts from the Lower Snake River Project on the Nez Perce, Yakama, Umatilla, Warm Springs, and Shoshone Bannock Tribes ("Tribal Circumstances Report") was prepared by Meyer Resources, Inc. on behalf of the Columbia River Inter-Tribal Fish Commission with funding from the Army Corps of Engineers ("Corps") for the NEPA process for the Lower Snake River dams.2 This report involved a significant amount of tribal coordination, was funded by the Corps, and was then utilized by the agencies as part of the NEPA process, including the environmental justice section. No similar approach was used in this EIS despite the fact that there is a significantly larger area scope in this NEPA process with a significantly larger number of impacted tribes. Instead, tribes were left to provide a vaguely defined set of information that may be incorporated in the NEPA process utilizing their own time and expenses. This is an unacceptable approach. We urge the agencies to reconsider this inadequate approach to assessing tribal impacts and to provide resources, which could include outside consultants selected in conceit with the tribes, to properly assess impacts of the CRSO to tribal communities.	The co-lead agencies analyzed effects to tribes throughout the Draft EIS. Human health is discussed in the following resources in Chapter 3: Water Quality, Power Generation and Transmission, Air Quality and Greenhouse Gasses, Navigation and Transportation, Recreation, Fisheries and Passive Use, Cultural Resources, Indian Trust Assets, Tribal Perspectives, and Tribal Interests, and Environmental Justice. Many of the Tribal Perspectives submissions discussed how important fisheries and the natural world are to tribal cultures, traditions, and lifeways. In terms of socioeconomics, effects to tribes were discussed throughout the Draft EIS. The co-lead agencies solicited tribal perspectives to incorporate into the EIS; there was no requirement for tribes to do so.
6364	17	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	e. Failure to Consider Economic Analysis of Improved and Functioning Columbia River Ecosystem: The economic benefits of the CRSO have largely been realized by lower river basin interests. The Tribe had requested the EIS fully analyze alternative operations that may promote economic development in the upper Columbia River Basin, including fisheries and recreation. Nowhere in the document is the natural capital assets described and evaluated/compared to the value of hydropower and navigation. This omission needs to be remedied. Earth Economics worked with Upper Columbia United Tribes, Columbia River InterTribal Fish Commission, Pacific Rivers, Save Our Wild Salmon, and WaterWatch of Oregon to develop The Value of Natural Capital in the Columbia River Basin report that shows the immense economic value of the Columbia River Basin's natural assets.3 In addition, it provides clear evidence of the increased value that can be gained by addressing ecosystem-based function in the Columbia River Basin river management. Currently, nature's value in the Columbia River Basin amounts to $198.8 billion per year in ecosystem benefits. A 10% increase in Ecosystem-Based Functions in the Columbia River Basin could result in a $219 .4 billion per year value in ecosystem benefits. The information and considerations in this report were not considered.	The types of activities and values assessed in the Earth Economics report are also evaluated within the CRSO EIS. However, framework and management scenarios described in the Earth Economics report are not directly comparable to the No Action and Action Alternatives evaluated in the CRSO EIS. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations.
6364	18	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	Moreover, the economic impact information provided by the Tribe in May 2019 to the agencies in its Tribal Perspectives comments was ignored, particularly the impact of the loss of salmon to tribal health and poverty. The Tribal Circumstances Report describes the intersection of dam construction and poverty- "The cumulative effects of dam construction have transferred potential wealth produced in the river basin from the salmon on which the tribes depend to electricity production, irrigation of agriculture, water transport services and waste disposal, these latter primarily benefiting non-indians. These transfers have been a significant contributor to gross poverty, income and health disparities between the tribes and non-Indian neighbors." Tribal Circumstances Report at 21. As of April 2018, the Benewah County unemployment rate was 5.8%, while State of Idaho's unemployment rate was 2.9% (Idaho Department of Labor, July 2018). Based on data from the American Community Survey, the 2016 poverty rate for the Coeur d'Alene Reservation was 18. 7%, while the poverty rate for the American Indian population was a staggering 38% (Table 1).4 Furthermore, thirty-six percent of Native youth live in poverty, compared to 21 percent of their non-Native counterparts on the Reservation.5 Mental health issues are persistent. Since 2015, four Tribal members died as a result of suicide, all under the age of 30 and two under the age of 17.	The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of Sections throughout the document. In particular, the cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries Section 3.15.2.1, which includes Sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries. Section 3.5.4, Tribal Interests, and 3.15, Fisheries and Passive Use, acknowledge the importance of salmon to public health to regional Tribes. Additional information has been added to the Environmental Justice section (Section 3.18) to explicitly recognize that "[t]he report goes on to describe principal causes of the present impoverishment of the study tribes include the loss of salmon and the loss of tribal lands (Meyer Resources 1999)."
6364	19	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	f. Inadequate Fish and Wildlife Mitigation: 2013 2014 2015 2016 The Purpose and Need section of the EIS includes provisions for the conservation of fish and wildlife resources, including threatened, endangered, and sensitive species throughout the environment affected by System operations. Further, the agencies are to comply with environmental laws and regulations and all other applicable federal statutory and regulatory requirements, including those specifically addressing the System such as requirements under the Northwest Power Act "to adequately protect, mitigate, and enhance fish and wildlife, including related spawning grounds and habitat, affected by such projects or facilities in a manner that provides equitable treatment for such fish and wildlife with the other purposes for which such system and facilities are managed and operated." 16 U.S.C. 839b(I I)(A). This necessarily requires mitigation to be well aligned with the Northwest Power and Conservation Council's (NPCC) Fish and Wildlife Program. The EIS, however, fails to adequately address operational impacts to fish and wildlife resources and lacks mitigation measures to account for these impacts. One of the strategies for mitigation of lost fish resources in the NPCC 2014 Program is consideration of re-introduction of anadromous fish into the blocked area, which entails investigation and evaluation of passage facilities highlighted below (NPCC 2014-12). IV. Strategies for how the FW Program will achieve goals C.3. Anadromous fish mitigation in blocked areas Principles: Restoration of anadromous fish to blocked areas should be investigated as mitigation for the impacts of hydropower dams that blocked passage (p. 83). General measures: Bonneville shall provide funding to consider passage projects to benefit native species in blocked areas (p. 84). With regards to reintroduction of anadromous fish above Chief Joseph and Grand Coulee dams, implement a phased approach that investigates reintroduction efforts that includes juvenile and adult fish passage at the dams (p. 84-85). Phase 1 will evaluate information from passage studies at other blockages and from previous assessments of passage at Grand Coulee and Chief Joseph dams; and investigate habitat availability, suitability and salmon survival potential in habitats above Grand Coulee. Phase 2 would entail activities to "design and test. . .interim fish passage facilities at the Dams", and to "identify additional studies to advance the fish passage planning process." Phase 3, based on Phase 2 results, would entail a decisionmaking process to "implement and fund reintroduction measures, including construction and operation of passage facilities."	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. Moreover, the co-lead agencies disagree with the assertion that they must consider anadromous fish passage and reintroduction into blocked areas above Chief Joseph and Grand Coulee dams to comply with the Northwest Power Act. The co-lead agencies note that the first phase of the Councils multi-step investigation of the feasibility of passage and reintroduction has not been deemed complete by the Council, as required by the 2014 Program before work on phase two takes effect.1/ In addition, the Council has noted that responsibility for the investigation and implementation of passage and reintroduction above Chief Joseph Dam is a broad regional and even national issue that does not fall entirely within the bounds of the Councils Program.2/ Therefore, the co-lead agencies do not need to include commitments in the EIS relating to the passage and reintroduction provisions in the Councils program to remain in compliance with their Northwest Power Act responsibilities. See response to Comment 6364-20. 1/Council, 2014 Program at 85. 2/See Council, 2014 PROGRAM, APPENDIX S, FINDINGS at 301 (the Council agrees that responsibility for the complete investigation and implementation of passage and reintroduction at these major blockages is ultimately a major policy decision for the region and nation and a shared responsibility that should not fall just on Bonneville and the ratepayers); Council, 2020 Addendum Findings at 87 (Mar. 2020) (making progress on this effort is not the sole province of the program.).
6364	20	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	The EIS dismisses consideration of anadromous fish passage and re-introduction into blocked areas, and is therefore inconsistent with mitigation provisions that are well established within the region prior to the District Court order for the agencies to conduct an EIS on systems operations. The Tribe has repeatedly contended that mitigation of the impacts of the FCRPS must include provisions for anadromous fish passage and re-introduction into blocked areas. This contention is consistent with the Northwest Power Act, the NPCC's Fish and Wildlife Program and the Purpose and Need of this EIS. This necessarily requires analysis of changes to infrastructure and operations at Chief Joseph and Grand Coulee Dams. By not recognizing these changes as necessary for mitigation, the agencies can neither recommend nor fund changes to the structure and operation of these facilities. Accordingly, the agencies should take concrete steps to amend the authorities granted under existing statutes, and identify within the EIS where new statutory authority	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, Federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps.

				may be needed to ensure that the Resource, Legal, and Institutional Purposes of the EIS are aligned with the contemporary realities of recovering endangered species as required by the ESA, and satisfying the requirements of the Northwest Power Act. The Upper Columbia United Tribes completed Phase 1 investigations concurrent with development of this draft EIS and a final report was reviewed by the Independent Scientific Advisory Board (ISAB) in 2019 (ISAB 2019-3). This report contains much of the information and technical analysis needed for a valid evaluation of environmental impacts and benefits, and can serve as a valid framework for mitigating the impacts to the blocked areas of the Upper Columbia River. Moreover, the development of the report was well coordinated with multiple tribal, federal, state, and other entities as warranted for such a complex, large-scale concept. This information was shared with the Action Agencies at multiple junctures during the early development of the DEIS. The regional managers will proceed to Phase 2 design and testing of passage facilities during implementation of the NPCCs 2020 Addendum to the Fish and Wildlife Program. As the region continues to pursue the phased approach to reintroduction, the Action Agencies by not addressing this in the EIS become increasingly disconnected from mitigation measures and the requirements prescribed by the Northwest Power Act.	Moreover, the co-lead agencies disagree with the assertion that they must consider anadromous fish passage and reintroduction into blocked areas above Chief Joseph and Grand Coulee dams to comply with the Northwest Power Act. The co-lead agencies note that the first phase of the Councils multi-step investigation of the feasibility of passage and reintroduction has not been deemed complete by the Council, as required by the 2014 Program before work on phase two takes effect.1/ In addition, the Council has noted that responsibility for the investigation and implementation of passage and reintroduction above Chief Joseph Dam is a broad regional and even national issue that does not fall entirely within the bounds of the Councils Program.2/ Therefore, the co-lead agencies do not need to include commitments in the EIS relating to the passage and reintroduction provisions in the Councils program to remain in compliance with their Northwest Power Act responsibilities. 1/Council, 2014 PROGRAM at 85. 2/See Council, 2014 PROGRAM, APPENDIX S, FINDINGS at 301 (the Council agrees that responsibility for the complete investigation and implementation of passage and reintroduction at these major blockages is ultimately a major policy decision for the region and nation and a shared responsibility that should not fall just on Bonneville and the ratepayers); Council, 2020 Addendum Findings at 87 (Mar. 2020) (making progress on this effort is not the sole province of the program.).
6364	21	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	g. Inadequate Consideration of Climate Change Effects: The EIS mentions the need to consider new information related to the Columbia River system. As the Ninth Circuit has recognized, an EIS that fails to meaningfully inform the public and decisionmakers regarding the climate impacts of a particular project is inadequate. Ctr. for Biological Diversity v. Nat'l Highway Traffic Safety Admin., 538 F.3d 1172, 1201 (9th Cir. 2008). To date, this draft provides very little information as to the effects of climate change, particularly as it relates to the blocked areas of the Basin. NEPA provides an obligation to the agencies to use "high quality information," 40 C.F.R. 1500.1 (b) and provide "full and fair discussion of significant environmental impacts," 40 C.F.R. 1502.1, including climate change impacts. As has been already mentioned in our scoping comments, the upper Basin habitats are projected to be the only remaining snowpack dominated systems remaining late into this century. Preparing for climate change by improving fish passage will be effective for increasing the diversity and availability of spawning and rearing habitats. Once again, we call into question the adequacy of this EIS when it does not address such a critical topic.	The technical and policy elements of this Draft EIS are in full compliance with binding the Corps' policy and guidance for qualitative assessment of climate threats and their plausible effects and impacts. The primary controlling policy and guidance are the the Corps' Climate Adaptation Policy Statement, signed by the Assistant Secretary of the Army for Civil Works in 2011, updated and signed again in 2013, and remains in force now; and USACE Engineering and Construction Bulletin 2018-14, "Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Projects." The numerical-model simulated outputs were evaluated by multiple technical means (see record of the full Corps Agency Technical Review), and were tested using the set of analytical measures created by the Corps Climate Preparedness and Resilience program to ensure that sound science and engineering compliance with the Corps' climate change policy and guidance. Those analytical tests are described in ECB 2018-14 (listed just above) and in the Corps' Engineer Technical Letter 1100-2-3, "Guidance for Detection of Nonstationarities in Annual Maximum Discharges." The assessment of climate threats and impacts is qualitative only in the sense that the biological and other impacts models did not directly ingest the physical hydroclimatology outputs modeled for the assessment. Those hydroclimatology outputs are fully quantitative and so can be the basis for refined estimates of effects and impacts should those be required following this Draft EIS. Regarding blocked areas, measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps.
6364	22	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	h. EIS must Analyze Compliance with the Clean Water Act articulated in Columbia Riverkeeper v. Wheeler: In December 2019, the Ninth Circuit ordered EPA to create a TMDL to address water temperature violations associated with CRSO. Columbia Riverkeeper v. Wheeler, 944 F.3d 1204 (9th Cir. 2019). The agencies must include the analysis of an alternative in the final EIS that includes measures necessary to comply with state and tribal water quality standards.	The Preferred Alternative complies with state and tribal water quality standards. Over the past two years, EPA has updated the RMB10 1D temperature model to assess Columbia and Snake River water temperatures and evaluate the impacts from the Federal dams as part of the reinitiation of the TMDL project. In parallel, the co-lead agencies developed the CRSO EIS system water quality model which consists of the 2-dimensional CE-QUAL W2 models and the 1-dimensional HEC-RAS models. Both models have been reviewed extensively by the agencies, which have concluded that both temperature models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As stated in EPA's review letter (#16-0059), EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS.
6364	23	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	1. Failure to Consider Operational Impacts: Many of the impacts that the operation of the Albeni Falls and Dworshak dams have on wildlife species and their habitats remain unresolved. These operations include but are not limited to hydropower, flood control, and fish flow mitigation. The daily, seasonal, and/or annual changes in operations can alter physical and ecological functions and processes, wetland and riparian character, vegetation communities, shoreline and riparian erosion cycles, and habitat structure, which can negatively influence terrestrial vertebrate and invertebrate communities. Operational impacts occur within and around, as well as upstream and downstream of reservoirs as a result of fluctuating water levels, flow, velocity, and temperatures. These impacts are expressed over time and will continue for the life of the hydropower projects. Settlement agreements have been reached with many of the affected parties from Albeni Falls Dam (Idaho Fish and Game and Kalispel Tribe) and Dworshak Dam (Idaho Fish and Game andNez Perce Tribe), but the Coeur d'Alene Tribe has never been mitigated for the operational impacts from these two dams. Mitigation for operational impacts at Albeni Falls and Dworshak dams to the Coeur d'Alene Tribe needs to be addressed in this EIS.	The operational impacts from Albeni Falls Dam and Dworshak Dam are described in Chapters 3 and 7. The Northwest Power Acts mitigation mandate pertains to fish and wildlife and their habitats, not the tribes and communities affected by the development and operation of the CRS. This comment concerns adverse impacts to the Coeur DAlene Tribe from the operation of Albeni Falls and Dworshak dams. The responses to comments to (Kalispel Letter 6106, comments 18 and 19) generally address this concern. Following the mandate to mitigate fish and wildlife and their habitats, Bonneville's 1992 settlement agreement with the State of Idaho and the Nez Perce Tribe addresses the construction and inundation impacts from Dworshak on wildlife and wildlife habitat. Dworshak inundated 16,970 acres. 1/ The settlement fully addresses this habitat loss and has a term of 60 years. The Nez Perce Tribes 2018 annual report indicates it has purchased 7,576 acres and still has over $9.5 million remaining in its mitigation fund established under the agreement. 2/ The State of Idaho also has a $3 million fund provided by Bonneville to manage the 60,000 acre Peter T. Johnson Unit of the Craig Mountain Wildlife Management Area (formerly known as Craig Mountain), which Bonneville purchased and transferred to Idaho. 3/ The agreement does not compensate the state or the tribe for any real property, economic, or cultural losses. The settlement, however, does leave open the question of operation impacts and does not address them. In the 2018 Albeni Falls Dam Wildlife Mitigation Agreement, Bonneville and the State of Idaho established that 14,087 acres had been mitigated through the efforts of the state and three tribes to address wildlife impacts from the construction and inundation of the dam (6,617 acres were impacted as a result of the construction and inundation of Albeni Falls Dam). 4/ In addition, Bonneville agreed to fund the State of Idaho to protect and enhance 1,279 acres of wetland habitat at the Clark Fork Delta and an additional 99 acres at the Priest River Delta to address the upriver effects of Albeni Falls operations. This is in addition to the 624 acres of wetland protected and enhanced on the Clark Fork Delta by IDFG, which was funded by Bonneville through a letter agreement in 2012. This settlement does not address operational impacts below the Dam. 1/ Idaho Department of Fish and Game, Phase I: Wildlife Protection, Mitigation, and Enhancement Planning: Dworshak Reservoir, at 3 (1988). 2/ Nez Perce Tribe, Dworshak Wildlife Mitigation Annual Report (2018) (on file with Bonneville). 3/ Idaho Department of Fish And Game, Craig Mountain Wildlife Management Area 2014-2023 Wildlife Management Plan 9 (Dec. 2014), https://idfg.idaho.gov/sites/default/files/2014-2023-CraigMtnWMA-Plan-Final.pdf. 4/ Northern Idaho Memorandum of Agreement Between the State of Idaho and the Bonneville Power Administration for Wildlife Habitat Stewardship and Restoration section II.C, page 5 (2018) (on file with Bonneville).
6364	24	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	J. Failure to Consider Secondary Impacts: One of the principles underlying impacts of hydropower construction and the subsequent inundation and operations are the secondary impacts that are in continuance with the life of the project. Power lines and construction pooling as well as river course and depth changes not only created habitat fragmentation but have forever changed the migration patterns and range use of wildlife species. These changes reduce the carrying capacity and continue to affect traditional Tribal resource use for generations. The loss of anadromous fish above Chief Joseph, Grand Coulee, and Dworshak dams has also had cascading effects throughout the ecosystem on the local wildlife populations. The lack of nutrients and available food that these fish would supply to the region has effects on species such as stream invertebrates, bald eagles, grizzly bears, and orca whales. The Coeur d'Alene Tribe has also experienced a tremendous shift from the past use of anadromous fish to other foods such as plants, wildlife and resident fish. The loss of salmon production in the blocked areas above Grand Coulee and Dworshak dams have directly led to the increased use of wildlife habitat and populations in this area. An assessment of the secondary impacts of hydro power construction should be initiated in order to fully realize the magnitude of impacts to native cultures with the loss of historical populations of wildlife that migrated through the system as well as any impacts found relevant to tribal culture.	Thank you for your comment. The scope of analysis is consistent with the baseline and proposed action for this EIS. Many of the cumulative effects and past actions referenced in this comment are included in the affected environment (Chapter 3) and Cumulative Effects (Chapter 6) sections of this EIS. Additionally, we explicitly acknowledge the magnitude of impacts to tribal culture, interests, and resources from development in the Columbia River basin. These acknowledgements and discussions are primarily contained in the Tribal Perspectives section (3.17) and associated appendices which were provided directly by the Tribes.
6364	25	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	. k. EIS must Address Operational Impacts to Cultural Resources: The EIS and any mitigation measures must address the impacts of hydro power operations on cultural resources and historical sites. Operations of Albeni and Dworshak dams, including deeper and longer drawdowns, can lead to exposure of sensitive sites and resources. The Native American Grave Protection and Repatriation Act ("NAGPRA") requires your agencies to "[t]ake immediate steps, if necessary, to further secure and protect inadvertently discovered human remains, funerary objects, sacred objects, or objects of cultural patrimony, including, as appropriate, stabilization or covering" 43 CFR 10.4(d). This requires the agencies to develop a long-term plan to stop or significantly improve the current erosion problems associated with dam operations.	In Section 5.2.1.6 of the Draft EIS, the co-lead agencies discuss the existing program that addresses system operational impacts on cultural resources. In Section 7.7.18, the co-lead agencies provide an archaeological resources impact analysis of the Preferred Alternative. In particular, Tables 7-47 through 7-50 in the Draft EIS demonstrate the comparison of all alternatives to archaeological resources across the system. These tables demonstrate operations at Albeni and Dworshak under the Preferred Alternative would decrease impacts to archaeological resources as compared to the No Action Alternative. The co-lead agencies discuss compliance with NAGPRA and the existing Cultural Resources program in Section 8.4.4 in the Draft EIS. NAGPRA does not require Federal agencies to develop long-term plans for prevention of erosion and other impacts.
6364	26	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	4. SECTION-BY-SECTION COMMENTS Executive Summary, Page 7, 2nd para: The court opinion was clear in its directive that the EIS should evaluate how to ensure that the prospective management of the CRS is not likely to jeopardize the continued existence of any endangered species. Nowhere in this document is fish passage above the blocked areas considered in this evaluation, therefore the evaluation is flawed and subject to legal challenge.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps.
6364	27	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	Executive Summary, page 10, para 2: This section outlines the agencies understanding of the Tribe's rights to manage natural resources and the trust responsibility of the United States to uphold historic trust obligations. The Tribe finds this section to be nothing but lip service; despite the status afforded tribes (as cooperating agencies), the number of meetings held, the number pages of comments developed, our words continue to be ignored or discarded.	The co-lead agencies remain willing to discuss the EIS during government-to-government consultation.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6364	28	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	Chapter 3 Affected Environment and Environmental Consequences: The loss of anadromous fish in the upper Columbia River Basin above Chief Joseph, Grand Coulee and Dworshak dams continues to have a broad array of impacts across the ecosystem. These fish would provide an addition of nutrients to the system when they return to spawn, and would also provide a food source to a wide range of wildlife species. These impacts should be discussed in Section 3.6.2.6 specific to grizzlies, eagles and orca whales. A discussion of these impacts should also be included in the sections that correspond with the No Action Alternative and Multiple Objective Alternatives 1-4 (Sections 3.6.3.2, 3.6.3.3, 3.6.3.4, 3.6.3.5, 6.6.3.6).	In the Draft EIS, the co-lead agencies developed and analyzed alternatives for future operations of the CRS, inclusive of the No Action Alternative. Effects to resources, including effects to vegetation and wildlife, were analyzed in Chapter 3. Effects were described relative to the No Action Alternative. As the co-leads are not proposing to reintroduce anadromous fish above Chief Joseph, Grand Coulee, or Dworshak, the impacts to the resources relative to loss of anadromous sources of nutrients would not change. Any loss of productivity due to lack of nutrients provided by salmon and steelhead carcasses does not change from the No Action Alternative under any of the alternatives.
6364	29	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	Chapter 7-2, entire first para: The Tribe understands that the agencies spent significant time meeting with Tribes to elicit and understand Tribal perspectives (some of these perspectives are captured here). The problem is it is not enough to understand our concerns. Our concerns must be addressed. The economic, tribal interests, and environmental justice sections lack any consideration of the cultural, health, and economic impacts of the loss of salmon caused by dam operations to the Tribe. To date, our concerns did not translate into a viable alternative that addressed fish passage above the blocked areas.	The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). The issue of fish passage above Chief Joseph and Grand Coulee Dams was determined to be outside the scope of the CRSO EIS. However, the co-lead agencies recognize the importance of this issue and have begun the process of convening a regional forum to discuss fish management in blocked areas.
6364	30	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	Section 7.7.4.1: Please add the following sentence to the first paragraph: "The Preferred Alternative will continue to prevent anadromous fish runs in Region A, Region B upstream of Chief Joseph and Grand Coulee Dams, and Region C above Dworshak."	The co-lead agencies recognize there are no anadromous fish above Chief Joseph Dam and the analysis in the EIS focuses on anadromous fish downstream of Chief Joseph Dam. Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS.
6364	31	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	Section 7.7.7 Vegetation, Wildlife, Wetlands, and Floodplains: The Preferred Alternative will continue to have secondary impacts on vegetation and wildlife in the blocked areas above Chief Joseph, Grand Coulee and Dworshak dams because of the absence of anadromous fish in the ecosystem. The food source and nutrients that these fish supply in the ecosystem have vast and cascading effects that are difficult to measure. A description of these impacts should be included in Sections 7.7.7.1, 7.7.7.2 and 7.7.7.3.	As stated in the Purpose and Need in Section 1.2, the ongoing action that requires evaluation under NEPA is the long-term coordinated operation and management of the CRS projects for the multiple purposes. As stated in the Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations, in the case where there is an ongoing management program or plan, the No Action Alternative would be "no change" from current management program or plan. The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 Code of Federal Regulations [CFR] 1502.14) and provides a benchmark for comparing environmental effects of the other alternatives. The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change at the time that the EIS development process began. Therefore, where impacts existed under the No Action Alternative (i.e. absence of anadromous fish above Chief Joseph, Grand Coulee, and Dworshak), the Preferred Alternative does not need to reflect those ongoing conditions.
6364	32	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	Section 7.7.8 Special Status Species: Implementation of the Preferred Alternative will impact species of special status in the basin due to the continued lack of a healthy anadromous fish population in the Columbia River basin above Chief Joseph and Grand Coulee dams. Anadromous fish would present a valuable food source for upper basin species such as grizzlies and eagles; while also increasing the amount of available food to imperiled species such as orca whales. A discussion of these im pacts should be included in the document.	In the Draft EIS, the co-lead agencies developed and analyzed alternatives for future operations of the CRS, inclusive of the No Action Alternative. Effects to resources, including effects to wildlife and special status species, were analyzed in Chapter 3. Effects were described relative to the No Action Alternative. As the co-leads are not proposing to reintroduce anadromous fish above Chief Joseph, Grand Coulee, or Dworshak, the impacts to the resources relative to loss of anadromous fish as food sources would not change. The availability of anadromous food sources for wildlife and special status species does not change from current conditions under any of the alternatives above Chief Joseph, Grand Coulee or Dworshak.
6364	33	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	Section 7. 7 .19 Indian Trust Assets, Tribal Perspectives, and Tribal Interests: The EIS states that "Effects to tribal interests under the Preferred Alternative would be negligible for most resources." The Columbia River Basin and the resources that it holds such as salmon are an integral part of Tribal culture. The continued absence of anadromous fish in the blocked area above Chief Joseph and Grand Coulee Dams is a major impact to the Coeur d'Alene, its members, and all of the Tribes in this area. The agencies' statements really amount to a comparison between status quo operations and the slightly modified Preferred Alternative, which lacks Upper Columbia fish passage and provides no ecosystem benefits to the Tribe. The federal government's trust responsibility to the tribes requires that the federal agencies meaningfully consider the tribes' interests. To meaningfully consider those interests, the EIS must include salmon and steelhead reintroduction to the habitats upstream of Grand Coulee and Chief Joseph dams. Discussion in this section should be changed to reflect that.	The issue of fish passage above Chief Joseph and Grand Coulee Dams was analyzed but eliminated from further consideration. The co-lead agencies recognize the importance of this subject, however, and have accordingly begun the process of convening a regional forum to identify and evaluate issues concerning fish management in blocked areas.
6364	34	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	Section 7.7.20 Environmental Justice: The Coeur d'Alene Tribe has long endured inequitable treatment by the federal agencies mandated to protect, preserve, and enhance fish and wildlife resources and sovereign Tribal Treaty and Executive Order rights. The Upper Columbia continues to be the most impacted by the Federal Columbia River Power System and least mitigated. The continued absence of anadromous fish in the blocked area above Chief Joseph and Grand Coulee Dams will continue to have an incalculable, adverse impact on tribal populations in the area. As discussed in the Tribe's May 2019 letter on Tribal Perspectives and the information above, the loss of salmon resulting from dams has had significant cultural, economic, and human health impacts to the Tribe and its members. These impacts are disproportionately high to tribal members who have an increased reliance on salmon for subsistence and cultural uses. The agencies cannot continue to avoid the Northwest Power Act's stated purpose: to protect, mitigate, and enhance the fish and wildlife, including related spawning grounds and habitat, of the Columbia River and its tributaries, particularly anadromous fish which are of significant importance to the social and economic well-being of the Pacific Northwest and the Nation and which are dependent on suitable environmental conditions substantially obtainable from the management and operation of the Federal Columbia River Power System and other power generative facilities on the Columbia River and its tributaries. 16 U.S.C. 839(6). Discussion in this section should be changed to reflect that.	The commenter believes that the loss of salmon resulting from dams is a disproportionately high impact to tribal members who have an increased reliance on salmon for subsistence and cultural uses. The environmental justice analysis in Section 7.7.20 considers the extent to which the Preferred Alternative has the potential to affect the availability of fish for commercial, ceremonial and subsistence fishing for Indian tribes, when compared to the No Action Alternative relying on analysis presented in Section 7.4 and 7.5, as well as Sections 3.5 and 3.15.4. This analysis found that under the Preferred Alternative, effects to environmental justice populations are not substantially different than the effects in the No Action Alternative. However, Section 3.15.2.1 acknowledges the loss of access to ceremonial and subsistence fishing in the Upper Columbia above the Grand Coulee and Chief Joseph Dams and these ongoing impacts. Under the Northwest Power Act, Bonneville provides funding to protect, mitigate, and enhance fish and wildlife affected by federal hydropower dams in the Columbia River basin, including the CRS, in a manner consistent with the Northwest Power and Conservation Council (Council) fish and wildlife program and the purposes of the Act. See 16 U.S.C. 839b(h)(10)(A). The Councils Program continues to include a mitigation funding allocation policy of anadromous fish (70 percent), resident fish (15 percent), and wildlife (15 percent). See 2014 Council Program, page 115. In addition, the Council has noted that, as a general policy, consistent with the intent of Section 2(6) of the Act, the Council has directed most of its habitat restoration funds for anadromous fish below blocked areas. See 2014 Council Program, at page 22. Through its Fish and Wildlife Program, Bonneville has funded a significant amount of mitigation in the Upper Columbia River Basin, consistent with guidance in the Councils Program. Recent examples of projects in the Upper Columbia River Basin, funded through Bonneville's Fish and Wildlife Program, include hatchery construction and improvement actions for Chinook, sturgeon, burbot, and trout; habitat restoration actions mitigating operational impacts; and new resident fish mitigation protecting thousands of acres in Montana, including extensive trout habitat that also provides significant wildlife benefits.
6364	35	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	5. CONCLUSION In conclusion, the Tribe believes that the agencies have failed to comply with their NEPA and trust obligations to the Tribe in its failure to take a "hard look" at fish passage in the Upper Columbia. Ample information exists for the agencies to consider such an alternative in the NEPA process. Moreover, it is clear that passage would provide an economic benefit to Columbia Basin tribes and the Region, in general. If fish passage is not going to be considered in the current EIS, the agencies must commit to completing a supplemental EIS that examines the issue. There is no need to create an entirely new forum to begin to discuss fish passage.	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 with the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making.
6364	36	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	The Tribe also requests that the public comment period be extended to provide additional opportunity to review the document or that the agencies afford the Tribe, through government-togovernment consultation, an opportunity to supplement these comments. We expect that the agencies will consider the Tribe's comments as it conducts its review fairly, openly, and in compliance with the law.	See response to Comment 6364-3.
6364	37	ajvitale@cdatribe-nsn.gov	Coeur d'Alene Tribe	We also expect the agencies to engage in government to government consultation with the Tribe prior to finalizing a final EIS and to meet its trust obligations to the Tribe.	Thank you for your request. The co-lead agencies have stated vigorously throughout the CRSO process that impacted Tribes can request government to government consultation at any time.
6367	1	maya.abels@gmail.com	N/A	In the last twenty years, tribal, federal state and independent research has repeatedly confirmed that removing or breaching the dams will return endangered wild salmon and steelhead back to a healthy and sustainable number.The orca scientists studying the Southern Resident Orcas and why they are perishing or seriously unhealthy, concludes that they are starving because their primary source of food: spring Chinook cannot be found for consumption. A new approach is urgently needed. The dams need a significant investment in deferred and regular maintenance for them to be viable. If these funds were diverted to breaching or removing the dams, the endangered Snake River fish population will return. There are numerous examples of how salmon return once a dam is breached or removed.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020).
6382	1	ja-wil@hotmail.com	N/A	In this time of carbon consideration, the last thing we should be thinking about is diminishing the greatest carbon-free and renewable generation system in the world. Carbon emitting baseload generation is being removed all over the region and cant be replaced with intermittent generation such as wind and solar. Wind and solar power cannot be compared to hydro when you look at the intermittency of wind and solar and the consistency of hydro. Eliminating the large amount of baseload generation provided by the four lower snake river dams will exacerbate the problem we are headed to which is resource adequacy. We cannot ignore the fact that we NEED a dependable electric grid. Our members live in a region that can have below zero temperatures for days on end. In the I-5 corridor, a blackout would be a serious and bothersome nuisance, but in northwest Montana where the temperatures can be below zero for days, people can die. It is very important to recognize that the CRSO Draft EIS shows that losing the Lower Snake River Dams would double the risk of region-wide blackouts.	The measure to breach the four lower Snake River dams that was evaluated in MO3, was not included in the Preferred Alternative (PA) identified in the Draft EIS. The effects of the PA on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the PA. However, because of the shape of the remaining hydropower generation in the PA, the loss of load probability was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary. The EIS analyzed two resource portfolios to replace the hydropower generation of the four lower Snake River dams, both of which maintain regional power system reliability. See Draft EIS, Section 3.7.3.5, at pages 3-904-910. Under these replacement portfolios, regional power rate pressure increases. Without replacement resources, however, the statement about the effects of breaching the four lower Snake River dams on regional resource adequacy and power reliability is consistent with the findings of the EIS. See Section 3.7.3.5, Effects on Power System Reliability, at page 3-903; and Appendix H, Table 2-1 in the Draft EIS. The statement in the comment that renewables cannot directly replace hydropower is also consistent with the findings of the EIS replacement resource analysis. See Section 3.7.3.2, Potential Replacement Resources and Associated Costs, page 3-849; and Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907 in the Draft EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6382	2	ja-wil@hotmail.com	N/A	I support a strong and viable salmon population in the northwest but salmon alone cannot be the sole decision criteria when considering the fate of the Lower Snake River Dams. Nor can these dams be the sole blame for changing salmon populations. More emphasis needs to be put on ocean conditions, predator control, and other factors impacting salmon numbers and a comprehensive, shared solution be developed that recognizes the important need for clean and reliable power service for this modern world.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6387	1	Daniel Dauwalter	Western Division of the American Fisheries Society	First and foremost, WDAFS believes that the public comment period for the CSRO DEIS should be extended for at least another 60 days (to June 13, 2020) to allow for a full assessment of the DEIS. We were not able to review the entire document because of its length and disruptions to daily life due to the COVID-19 pandemic.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website reminded the public on April 9, that they should plan to submit comments by the close of the comment period.
6387	2	Daniel Dauwalter	Western Division of the American Fisheries Society	We were not able to review the entire document because of its length and disruptions to daily life due to the COVID-19 pandemic. Since an extension is not certain, the WDAFS provides these brief comments that focus on fisheries impacts due to the Preferred Alternative and select other alternatives evaluated in the DEIS. WDAFS understands that the CSRO DEIS addresses difficult policy trade-offs between electricity, transportation, flood control, irrigation water, recreation, fish, culture, and other values. WDAFS comments focus on the fisheries science contained in the DEIS, particularly as it relates to the Endangered Species Act (ESA), sustainability, and harvest opportunities. The DEIS states that the purpose of the public review is to seek input on the alternatives considered, effects of the alternatives, and associated mitigation. We have used these three topics as outlined in our review below. Alternatives considered: The DEIS should have included an alternative that included fish passage or reintroduction upstream of Grand Coulee and Chief Joseph dams. One of the largest impacts to CRSO Salmon and steelhead abundance was the construction of these dams that were built without fish passage and therefore eliminated access to a large and productive portion of the Columbia Basin. Although we understand the political challenges associated with fish passage into the blocked areas, we do not think it is appropriate to leave this very important action out of the alternatives considered. Reintroduction of anadromous fish into the blocked area is among the most likely alternatives that could be implemented to increase natural production of salmon and steelhead in the Columbia Basin. E	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public hearings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate as per NEPA regulations. The Corps notified the public on April 9 that they should plan to submit comments by the close of the comment period. Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps.
6387	3	Daniel Dauwalter	Western Division of the American Fisheries Society	Effects of the alternatives: Based on analyses presented in the DEIS and fisheries objectives set by councils and partnerships in the basin, the Preferred Alternative in the DEIS will not allow for self-sustaining, natural origin, and harvestable anadromous fish populations throughout the Columbia River basin, and only the MO3 Alternative that includes breaching the four Lower Snake River dams is the best alternative to achieving abundant natural-origin, fishable, and harvestable populations of spring/summer Chinook salmon and steelhead in the Snake River. The Northwest Power and Conservation Councils (NPCC) smolt-to-adult return ratio (SAR) objectives required to support recovery and tribal and non-tribal harvest goals for ESA-listed Snake River and upper Columbia River salmon and steelhead are stated to be 2%-6% (4% average, 2% minimum) (NPCC 2014). These SAR objectives were based on analyses demonstrating a median SAR of 4% was necessary to meeting National Marine Fisheries Service (NMFS) 48-year recovery standard for Snake River spring/summer Chinook salmon; meeting the interim NMFS 100-year survival standard required a median SAR of 2%. The Columbia Basin Partnership, a diverse group of 31 Columbia Basin stakeholders and sovereigns, including representatives of the four Columbia Basin states, tribes, ports, public power entities, irrigators, commercial and recreational fishers, and conservationists, have set even more ambitious but agreed-upon goals for recovering healthy and harvestable salmon and steelhead populations in the basin. The CRSO DEIS presents predictions of Snake River spring/summer Chinook salmon SARs under various scenarios, including the Preferred Alternative, using two models: NOAAs Life Cycle Model (LCM), and the Comparative Survival Study (CSS). When considering the NPCC and Partnership objectives stated above, the Preferred Alternative presented in the DEIS will not even result in recovery (minimum viable populations) of ESA-listed salmon and steelhead based on the LCM, whereas the CSS suggests that achieving recovery might be possible but achieving self-sustaining, natural origin, and fishable and harvestable populations is clearly not. In addition, other actions will be necessary to improve survival of other listed populations that will not benefit appreciably from breaching the Lower Snake River dams.	Harvest certainly has an impact on salmon and steelhead populations. NMFS recently completed at EIS evaluating harvest. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. The 2-6% SAR target referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals would necessitate actions by many parties. Based on the analysis of the Preferred Alternative, it will make a contribution to recovery, but the Councils broad-sense recovery goals are beyond the scope of this EIS, which only contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That determination however is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Life Cycle model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase - smolt-to-adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River spring/summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict MO3, the alternative that includes the measure to breach the lower Snake River dams, is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. As acknowledged, harvest has an impact on salmon and steelhead populations. NMFS recently completed at EIS evaluating harvest. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and.
6387	4	Daniel Dauwalter	Western Division of the American Fisheries Society	Tables 3-61 and 7-25 of the DEIS clearly show that the LCM predicts a maximum SAR of 1.0 under the MO3 Alternative, and the SAR under the Preferred Alternative ranges from 0.81 to 1.12% (high estimates assume no latent mortality). The CSS predicts the highest SAR for the MO3 alternative at 4.3%; the CSS SAR estimate for the Preferred Alternative is 2.7%. The CCS SAR estimates for Snake River steelhead are also highest under alternative MO3; the LCM does not have SAR estimates available for steelhead. More specifically, recent analyses for the CSS also show that major population declines of Snake River spring/summer Chinook salmon and steelhead are associated with SARs less than 1%, and increased lifecycle productivity has occurred in years that SARs exceeded 2% (DeHart et al. 2019). Pre-harvest SARs in the range of 4% to 6% are associated with historical (pre-FCRPS) productivity for Snake River spring/summer Chinook salmon. Historical levels of productivity for John Day River spring Chinook salmon are associated with pre-harvest SARs in the range of 4% to 7%. Major population declines were associated with SARs (LGR - GRA) less than 1%, and increased life-cycle productivity as SARs exceeded 2%. Again, these model predictions suggested the Preferred Alternative will not allow for self- sustaining, natural origin, and harvestable anadromous fish populations throughout the Columbia River basin.	The co-lead agencies used current high quality data and the best available science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used both two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. SAR values reflect the methods used for estimation, and this should be taken into account when comparing estimates against the Council's regional SAR objectives for recovery. The Council did not prescribe a specific method of SAR calculation. SARs reported by hatcheries using coded wire tags often incorporate a harvest correction factor for ocean, recreational and Tribal harvest. Due to the different approaches of the models, including the length of the historical survival time series, use of different hatchery and natural origin populations, and other factors, the two models estimated substantially different SAR under the No Action Alternative for Snake River spring Chinook: 0.88% from the COMPASS model, assuming no latent mortality, and 2.0% SAR from the CSS lifecycle model, which is at the low end of the Council's targeted range for recovery. Different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Life Cycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase (SARs for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River spring/summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. Please see Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
6387	5	Daniel Dauwalter	Western Division of the American Fisheries Society	Mitigation: WDAFS recommends quantifying the impacts to fish from CSRO and comparing those impacts to quantitative estimates of the improvement to fish caused by mitigation actions (e.g., hatcheries, habitat actions in tributaries and estuary). An objective mitigation standard might be to achieve no-net-loss. Although the DEIS states qualitative objectives of improving juvenile and adult survival, it is not clear how much improvement is needed to meet objectives for recovery of ESA-listed populations. Improvements relative to the No Action Alternative seems insufficient to evaluate whether improvements are enough to meet mitigation and achieve viability standards. This makes it difficult to evaluate how much mitigation is appropriate.	Quantitative evaluations were conducted to determine the effects of each of the alternatives when appropriate. In instances when quantitative evaluations were not appropriate or possible, qualitative discussions are included to describe the effects of each of the alternatives. The evaluations are clear, transparent, and repeatable based on the best available information. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery.
6387	6	Daniel Dauwalter	Western Division of the American Fisheries Society	Questions that need answers: It would be helpful if the DEIS contained answers to the following questions in order to help readers interpret the conclusions and recommendations provided in the DEIS. We acknowledge that some of the answers may be found in the DEIS, but we have not been able to read and comprehend fully the entire DEIS in light of the time constraints associated with COVID-19. If the answers to our questions are provided, then please direct us to those sections. Otherwise, we recommend including the answers to the questions and associated data or sources in the DEIS. 1) What are the SARs of CRSO relative to a) historic SARs, and b) contemporary SARs in dammed and undammed rivers along the Pacific Coast?	The co-lead agencies analyzed alternatives relative to the No Action Alternative. While both absolute and relative changes compared to the NAA for all metrics are presented in chapter 3.5 and chapter 7, in the case of Smolt-to-Adult return (SAR) rates, the CSS and NOAA modelers caution that their results are better suited for relative comparisons rather than as absolute values. Therefore comparison of modeled SARs to historic SARs or undammed rivers would not be instructive. Specific to presenting SARs from other rivers, the co-lead agencies follow the guidance from the Independent Science Advisory Board, and do not typically weigh performance of one population vs. another. It is difficult to isolate causative factors in those types of comparisons (ISAB 2020-1).
6387	7	Daniel Dauwalter	Western Division of the American Fisheries Society	2) How much of the SARs and adult-to-adult mortality can be attributed to CRSO relative to other factors such as natural, harvest, habitat, predation, hatcheries, and other relevant factors?	Thanks for your comment. The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams and these effects are included in SARs. The CRSO Draft EIS did not attempt to separate out CRS effects on SARs from other factors, but rather used SARs to compare across the range of alternatives. The Draft EIS also presents other metrics that are more directly related to the CRS, including in-river system survival, travel time, and the proportion of fish that pass through different passage routes. However, given the hypothesis that the operation and maintenance of CRS dams can affect the survival of fish in their ocean phase, SARs became a key metric in analyzing the alternatives because this latent effect is not captured by the more direct metrics that can be measured within the CRS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6387	8	Daniel Dauwalter	Western Division of the American Fisheries Society	3) What portion of the total mortality should CRSO be responsible for avoiding, reducing, or mitigating for compared to other users?	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. While meeting the regional SAR goals developed by the Northwestern Power and Conservation Council is a worthwhile endeavor, it is a recovery goal. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
6387	9	Daniel Dauwalter	Western Division of the American Fisheries Society	4) Can a combination of natural and hatchery production achieve ESA delisting (i.e., meet goals and objectives in recovery plans) as well as desired harvest levels under the alternatives considered?	Hatchery programs are included in the No Action Alternative and would be expected to continue under alternatives MO1, MO2, and MO4, and certain hatcheries would continue under MO3. No new hatchery programs are considered as mitigation under any alternatives, but MO3 does include increased hatchery production due to short-term impacts from breaching the four lower Snake River dams. Diversity is an important factor in an ESU's ability to persist and adapt, and is one of the factors considered in assessing an ESU's long term viability, along with abundance, productivity, and spatial structure. There is an extensive body of literature developed from studying these factors and managing the conservation of salmon and steelhead, including hatcheries as one tool. Hatchery programs have long been a part of the approach for salmon recovery. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as proposed under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery programs are proposed. Figure 3-111, which combines hatchery and wild fish, in the Draft EIS was an illustration that the CRS can and has supported large numbers of returning adult salmon and steelhead. Over time, the Preferred Alternative is anticipated to benefit both wild and hatchery fish. Hatchery origin fish are very important to tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. The three co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS and continue to support information developed by the Hatchery Scientific Review Group and the Northwest Power and Conservation Council's Three-Step Review process. The co-lead agencies do not have authority over tribal, commercial or recreational fishing; however, through increased abundance anticipated under the Preferred Alternative, more fish may be available for catch.
6387	10	Daniel Dauwalter	Western Division of the American Fisheries Society	5) If breaching were to occur, would all hatchery production and associated monitoring and evaluation (M&E) cease? How would this influence harvest and science in the region?	The Draft EIS acknowledges that with the breaching of the four lower Snake River dams in MO3, there would no longer be an obligation to fund the Lower Snake River Compensation Plan, which accounts for much of the hatchery production in the basin and other mitigation activities could be adjusted. RM&E associated with the remaining hatchery production would be reevaluated at that time. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. The fish models are based upon data collected from past fish runs and there is no data available to inform a quantitative analysis for wild fish in the absence of hatchery fish. Over time, increased returns of wild fish would be expected as wild fish replace hatchery fish, and the Snake River resident fishery would improve as the reservoir habitats transition to riverine. The long term overall effect of MO3 would be beneficial for Snake River salmon and steelhead as well as resident fish, so no mitigation for this effect was identified. Additional hatchery production would be in place for limited years to offset the short term dam breaching and construction effects. Mitigation measures were proposed for both anadromous and resident fish for a transitional period for the breaching of the four lower Snake River dam embankments, as described in Sections 5.4.3.2 and 5.4.3.3. Proposed mitigation includes two years of hatchery production along with trap and haul operations for the anadromous fish during this period. These mitigation measures would reduce adverse effects to resident and anadromous fish in Region C. The three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and.
6388	1	John Smith	Clearwater County Board of Commissioners	We also recognize that the CRSO process, within the framework of the National Environmental Policy Act, looks to identify broad-based environmental and socio-economic impacts associated with the proposed alternatives. However, our belief after an in-depth review of the CRSO DEIS is that it does not take into consideration community economic sustainability. We do not support the CRSO DEIS because both direct and indirect economic impacts of its proposed actions on regional economies are not considered, which are as follows: Clearwater County is home to Dworshak Reservoir, the Dworshak National Fish Hatchery and Clearwater Hatchery provide direct local economic value through a number of avenues: federal jobs (USACE, USFWS), state jobs (ID Fish & Game, ID Parks & Rec), commercial vendors (licensed outfitter-guides, campground operations); and indirectly from the hospitality industry (hotels, eating establishments and retail). According to ID Fish & Game angler surveys, steel head fishing contributes$ 31,677,943 (inflation adjusted) are spent annually in the Clearwater River; and, throughout the region$ 80,815,718. An additional $4,614,444 in angler spending is directly contributed from fishing on Dworshak Reservoir. The Idaho Department of Labor Regional Economist recently provided multipliers of both jobs and income tied to steel head fishing in Clearwater County: [table] Jobs Average Earnings Job Multiplier Income Multiplier Outfitters & Guides 24 $23,221 1.54 1.70 Accommodation 55 $18,448 1.49 1.73 Restaurants & Bars 131 $14,692 1.33 1.63 Sporting Goods Stores 37 $35,831 1.55 1.76	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. In addition, Appendix Q, Annex C, and Section 3.19.3 describes the jobs and income supported by the CRS implementation and system operations, which includes Federal and contractor jobs, as well as multiplier effects (indirect and induced jobs and income). A qualitative description of where these economic benefits would be supported is also described in this section.
6388	2	John Smith	Clearwater County Board of Commissioners	The importance of angler spending cannot be understated in rural economies. We do not understand why the CRSO DEIS suggests proactive coordination with Libby and Hungry Horse Reservoirs related to drawdowns and resident fish impacts but no such concern given to the Dworshak community. The Dworshak community has aggressively, over the past decade, marketed the bass and kokanee fishery in Dworshak while still maintaining the importance of the resident fish well-being. In fact, the first and second largest record small mouth bass in Idaho were caught in Dworshak. Since, as previously noted, angler spending is a valued component in Clearwater County's economy, why are resident fisheries not considered equally throughout the CRSO network?	The Recreation Section 3.11.2 and 3.11.3.2 (No Action Alternative) and Appendix M describe the estimated visitation, social welfare, and regional economic effects associated with visitation at Dworshak, including fishing visitation. Dworshak reservoir elevations could be lower in January through March during wet years in as a result of the Slightly Deeper Draft for Hydropower (Dworshak) measure. During typical water-level years, there would be no differences in water surface elevations compared to the No Action Alternative. During wet years, there would be only minor effects to visitation and social welfare compared to the No Action Alternative. As described in Section 7.7.5, there would be small adverse impacts to resident fish from entrainment from this measure at Dworshak.
6388	3	John Smith	Clearwater County Board of Commissioners	The CRSO DEIS makes mention of a 2019-2021 Spill Operations Agreement. We learned from Corps staff that the Spill Operations Agreement is a negotiated spill regime between co-lead agencies, (Nez Perce Tribe and States of Oregon and Washington) for implementation in the Lower Snake River and Lower Columbia River Dams. It has been suggested that smolts historically made the downstream migration from the upper reaches of the Clearwater River system to the ocean in days and that with the slack water pools the trip takes months. We support and applaud the following in the Spill Operations Agreement: The measures proposed in the CRSO DEIS to reduce predation on downstream anadromous smelts. We support these predator control measures and encourage an aggressive approach to reducing avian predation of anadromous smelts. We applaud efforts that will increase flow in the pools enabling swifter migration of smelts through the CRSO hydro system.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. Regarding smolt travel time: the effect of the Preferred Alternative on travel time is presented in Chapter 3, section 5, and Chapter 7 in the Draft EIS. In general, Snake River spring migrants take about 16 days to migrate through the CRS under the No Action Alternative. Under the Preferred Alternative, travel time is reduced by approximately 1 day for Chinook.
6388	4	John Smith	Clearwater County Board of Commissioners	The CRSO DEIS mentions a Zero Generation Opportunity, which would allow flow through dams without electricity generation. The proposal would extend the Zero Generation Opportunity from mid Dec - Feb to Oct 15 - Feb 28, when power markets warrant and river conditions make it feasible. The CRSO DEIS also states that a slightly deeper Dworshak would increase water flow through turbines Jan - March with a focus on hydropower generation because the power demand markets are higher in winter across the CRSO. It seems the Dworshak water is being used for power generation to enable the Zero Generation Opportunity in the lower Snake-Columbia system. Dworshak has been tapped for years to augment flows for outmigrating anadromous fish. We do not support the elements in Zero Generation Opportunity for the following reasons: The Zero Generation Opportunity seasonal extension seems contradictory to the statement of the regional demand for power being greater in the winter. The additional winter season hydro power generation being considered for upper CRSO system storage facilities seems unsubstantiated (i.e. Libby is also a storage facility and has more generating capacity than Dworshak).	The commenter may be conflating two different issues. Drafting Dworshak slightly deeper has the power benefits described in the EIS. Dworshak often fills too quickly in the spring and then has forced spill to meet flood risk management operations. Spill at Dworshak leads to high TDG in water entering the lower Snake River which could adversely impact anadromous fish. Drafting slightly deeper commensurate with the water supply forecast above Dworshak would reduce the incidence of forced spill and provide power benefits described in the EIS. Due to the sensitivity around refill for summer cooling water, the developed process would use a higher probability of refill than what is used at other headwater projects (Grand Coulee and Hungry Horse). As shown in Section 7.7, Figure 7-12 and Table 7-14 in the Draft EIS, this operation does not measurably affect the elevation at the beginning of April or the flow in April except around the highest 1% of water conditions when flood risk management is an issue. The Zero Generation Operations measure, which is included in the Preferred Alternative, allows the lower Snake River projects to reduce generation during night-time hours when loads are lower. This reduction in generation decreases the outflow on the project which allows for water to be stored in the reservoirs for use later in the morning during high winter load peaks. Increasing water flows from Dworshak during January through March with the Zero Generation Operations measure would allow for more peaking capability on the lower Snake projects to meet high winter load peaks.
6388	5	John Smith	Clearwater County Board of Commissioners	In the slightly deeper Dworshak scenario the CRSO DEIS should consider the impact on resident fish. Bass spawning typically occurs when water temperatures hover around 60 degrees F, which in the Dworshak neighborhood is April - May. Given lower water levels in spring and the CRSO EIS lack of inclusion of any climate change assessment on water availability, a slightly deeper Dworshak could have negative impacts on resident smallmouth bass, a highly valued recreational fishery and growing economic engine in Clearwater County's economy. Additionally, the graphs in Figure 7-13 suggest the slightly deeper Dworshak would reach full pool the last week of June and the previously negotiate Dworshak drawdown for fish outmigration begins July I, resulting in a l week full pool recreational opportunity. We do not support the slightly deeper Dworshak scenario for the following reasons: There is no consideration to the impact on resident fish and strong potential for negative impacts on resident small mouth bass. There is no analysis of resident fishery impacts as a result of a slightly deeper Dworshak? The climate change has not been considered in the CRSO DEIS in regard to snowpack and water availability There are no funding resources allocated to Dworshak Reservoir to facilitate water access during the slightly deeper Dworshak levels (boat ramp extensions) for public safety. There are no additional funding resources committed to offset the known negative impacts summer time drawdown has on Dworshak recreation (dock improvements, on water destination facility expansion, campground improvements, OHV use area/camping improvements).	Figures 7-12 and 7-13 offer different ways to view the elevation hydrograph, but both figures indicate the elevations would be very similar to the No Action Alternative by the time smallmouth bass would begin spawning in April or May and remain similar to the No Action Alternative through the summer and fall. Figure 7-13 illustrates the hydrograph in dry, average, and wet years. In this figure the No Action and Preferred Alternative hydrographs are nearly identical in average and wet years during April through June, and in dry years the elevation would be higher than the No Action Alternative at times during these months. The deeper draft is seen in January, February, and partly into March, especially in the wet years, in which the elevation would be lower than the No Action Alternative for a particular date in those months; in other words the reservoir would draft faster and earlier than the No Action Alternative, but it would not result in drawdowns any lower than the No Action Alternative at the lowest point. Effects to smallmouth bass are expected to be negligible. Boat ramps access would be the same as the No Action Alternative during months when they would be in use, and the summer drawdown would also be the same as the No Action Alternative, so mitigation would not be required by NEPA. Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives.
6389	1	jonesh34@wwu.edu	N/A	See attached document for comment	Unfortunately, an attachment was not received from the commenter. The co-lead agencies requested the commenter resubmit via e-mail on June 25, 2020; however, the co-lead agencies did not receive a response to this request.

6411	1	paul@iwua.org	Idaho Water Users Association	IWUA members have long expressed interest in matters involving the Columbia River and salmon and steelhead recovery. During their 2020 Annual Convention, IWUA members adopted the following resolution: 2020-11: Federal Columbia River Power System WHEREAS, In May 2016, a federal judge struck down the 2014 biological opinion for the Federal Columbia River Power System (FCRPS) and ordered that the federal action agencies study the possible removal of one or more dams on the lower Snake and Columbia Rivers; and WHEREAS, The federal judge has ordered that the existing biological opinion remain in place until 2018 and that the National Environmental Review Process for the FCRPS be completed in 2021; and WHEREAS, A federal judge ordered that spill be increased at the lower Snake and Columbia River dams to the maximum level on a 24/7 basis; and WHEREAS, The court-ordered spill operations are experimental and may harm salmon by causing gas bubble disease in juvenile salmon and prevent returning adult salmon from ascending fish ladders to reach their spawning grounds; and WHEREAS, The Columbia-Snake system is the top wheat export gateway in the U.S., with barging on the Snake River handling nearly 10% of all U.S. wheat exports, and half of the wheat grown in Idaho; and WHEREAS, It would take over 43,000 rail cars or over 167,000 semitrucks to move the cargo that moves by barge on the lower Snake River; and WHEREAS, The lower Snake River dams provide enough clean energy to power 1.87 million homes; and WHEREAS, Removing the lower Snake River dams would have a significant negative impact on our economy and environment by eliminating more than 1,000 megawatts of carbon-free energy, increasing greenhouse gasses by 4.4 million tons per year and severely reducing navigation capacity, including the Port of Lewiston; and WHEREAS, The cost of removing the lower Snake River dams is estimated between $274 million and $372 million annually; and CRSO Draft EIS Comments April 13, 2020 Page 3 WHEREAS, Juvenile fish survival rates past each of the lower Snake and Columbia River dams are between 95% and 98%; and WHEREAS, Dam improvements have resulted in improved fish returns with a sustained increase in salmon populations. NOW, THEREFORE, BE IT RESOLVED, That the Idaho Water Users Association is opposed to removal of any of the lower Snake and Columbia River dams and is also opposed to the court-ordered spill increases at the dams. BE IT FURTHER RESOLVED, That the Idaho Water Users Association supports the existing 2014 FCRPS biological opinion remaining in place until a subsequent biological opinion is adopted and in effect.	Thank you for sharing the resolution passed by the Idaho Water Users Association.
6411	2	paul@iwua.org	Idaho Water Users Association	The Committee of Nine is the official advisory committee for Water District 01, the largest water district in the State of Idaho. Water District 01 is responsible for the distribution of water among appropriators within the water district from the natural flow of the Snake River and from Reclamation storage reservoirs on the Snake River above Milner Dam. The Committee of Nine is also a designated rental pool committee that has facilitated the rental of storage water to Reclamation for flow augmentation pursuant to biological opinions. The undersigned Counsel for the CO9 is a sitting member of the Idaho Governors Salmon Workgroup.	Thank you for your comment.
6411	3	paul@iwua.org	Idaho Water Users Association	IWUA members throughout southern Idaho depend on the Snake River and its tributaries for water storage, hydropower, recreation, flood prevention and other purposes. Development of the river has resulted in a thriving agricultural economy. Today, millions of acres are farmed throughout southern Idaho. In 2019, cash receipt from the sales of crops and livestock in Idaho were $8.3 billion.2 Net farm income was $2.7 billion.3 Irrigated Agriculture is responsible for over 112,000 Idaho Jobs 12% of the total workforce. 4 Reclamation estimates that development along the Snake River and its tributaries in Southern Idaho has contributed billions of dollars to Idahos economy: 5 Reclamation and Idaho water users have worked hard to balance the development and management of Idahos river systems including for fish and wildlife. In addition to irrigation, 2 The Financial Condition of Idaho Agriculture: 2019 (Eborn & Taylor) (2020) 3 Id. 4 Taylor, Garth, The Contribution of Irrigated Agriculture to the Idaho Economy (2017) 5 Bureau of Reclamation (2017) Boise Project Minidoka Project Owyhee Project Palisades Project Crops $624,575,000 $704,104,000 $155,250,000 $650,900,000 Livestock $645,000,000 $387,144,000 $93,150,000 $355,448,000 Power Generation $13,975,000 $6,339,200 $0 $31,413,000 Flood Prevention $183,287,500 $9,961,600 $755,550 $20,942,000 Recreation $33,002,500 $28,300,000 $4,830,000 $16,640,400 TOTAL $1,499,840,000 $1,135,848,800 $253,985,550 $1,075,343,400 CRSO Draft EIS Comments April 13, 2020 Page 4 flood control, hydropower generation and recreation, many of Idahos reservoirs incorporate operations for fish and wildlife benefits.	The statements and information presented in this comment are generally consistent with the findings of the EIS. Regarding the support for comments submitted by Lewiston and Clarkston, those comments are addressed in the responses to those comments.
6411	4	paul@iwua.org	Idaho Water Users Association	II. Comments IWUA and CO9 provide the following comments regarding the CRSO DEIS. A. The Scope of the CRSO DEIS is properly limited. IWUA and CO9 support the decision by the Agencies to exclude the Upper Snake River and its tributaries from the analysis of the CSRO DEIS. CRSO DEIS at 1-1 (Projects in the upper Snake, Willamette, and Rogue River Basins are excluded from the CRS because these are coordinated and operated separately) (emphasis added). In 2004, the State of Idaho, the Nez Perce Tribe and Idaho water users entered the Snake River Water Rights Agreement, which was ratified and adopted by Congress in the Snake River Water Rights Act of 2004 (the Nez Perce Agreement). 6 That agreement resolved disputed tribal water right claims for the Snake River and its tributaries. This settlement agreement included several provisions to resolve disputed tribal water right claims for the Snake River and its tributaries. It also quantified tribal water rights and established trust funds for water and fisheries resources. As it specifically relates to the Snake River and its tributaries above the Hells Canyon Complex, the Nez Perce Agreement established a Biological Opinion and flow augmentation program. Pursuant to the agreement, each year up to 487,000-acre feet of Idaho water is passed through the Upper Snake River system (including its tributaries) to assist with downriver migration of juvenile salmon and steelhead. This water, which comes from the federal government, state of Idaho and water users/spaceholders, could otherwise be used for agricultural or other uses, but is left in the river. In return for the flow augmentation program, the parties agreed to a 30-year biological opinion. The Nez Perce Agreement describes the biological opinion, and its relation to the FCRPS, as follows: Biological Opinions will be issued for the term of this agreement which will provide incidental take coverage, if necessary, for all federal actions and related private actions including: (1) all BOR actions in the upper Snake River basin, (2) all private depletionary effects in the Snake River basin above the Hells Canyon Complex to the extent they affect listed anadromous fish, and (3) all private depletionary effects above the Hells Canyon Complex to the extent that they are related to the federal action and affect listed resident species. 6 Information about the settlement agreement can be reviewed at https://idwr.idaho.gov/IWRB/waterplanning/minimum-stream-flows/nez-perce-agreement.html. CRSO Draft EIS Comments April 13, 2020 Page 5 These Biological Opinions shall be separate from any Federal Columbia River Power System (FCRPS) Biological Opinion. (emphasis added).7 Importantly, the biological opinion has a term of 30 years (through 2034), with an opportunity to extend for an additional 30 years upon mutual agreement. Limiting the scope of the CRSO DEIS to exclude the Snake River above the Hells Canyon Complex is consistent with the Nez Perce Agreement. These matters should remain separate and the Agencies should reject any efforts to include the Upper Snake River in their considerations of the FCRPS.	Thank you for your comment.
6411	5	paul@iwua.org	Idaho Water Users Association	B. Removal of the Lower Snake River Dams is Not Warranted. As required by the Opinion and Order issued by the U.S. District Court for the District of Oregon, 8 the CRSO DEIS considered the effects of breaching the four Lower Snake River dams (LSRD). The CRSO DEIS provides extensive analysis of the environmental, economic, social and cultural impacts of breaching the LSRD. Ultimately, however, the Agencies determined that, despite benefits to fish associated with breaching, the adverse impacts to region were too great. Instead, the Agencies chose an alternative that balances the multiple uses of the system, while providing for the recovery of salmon and steelhead. Despite the major benefits to fish expected from MO3, this alternative was not identified as the Preferred Alternative due to the adverse impacts to other resources such as transportation, power reliability and affordability, and greenhouse gas emissions. The co-lead agencies used the analysis in MO3 to inform and improve the development of the Preferred Alternative that seeks to balance managing the system for all purposes while providing additional benefits for fish and other study objectives. (CRSO DEIS Executive Summary at 29) IWUA and CO9 know that salmon and dams can coexist. The CRSO DEIS confirms this fact. Therefore, the Agencies properly rejected MO3 as the preferred alternative. The Agencies analysis shows that, with tailored spill programs and some modifications to the LSRD passage structures, salmon and steelhead can be recovered and the region can avoid the dramatic and devastating impacts of dam breaching.	Thank you for your comment and support of the Preferred Alternative.
6411	6	paul@iwua.org	Idaho Water Users Association	We urge the Agencies to ensure that the analysis in the CRSO DEIS particularly relating to MO3s breaching alternative adequately discusses the economic impacts of the various alternatives. This includes impacts to navigation and those wheat farmers and others who rely on river transportation, sportsmen and other recreational industries and irrigation interests 7 See page 18 of the settlement agreement. https://idwr.idaho.gov/files/iwrb/2004/20040420-Nez-Perce-AgreementMediators-Term-Sheet.pdf. 8 National Wildlife Federation, et al. v. National Marine Fisheries Service, et al., 184 F. Supp. 3d 861 (D. Or. 2016). CRSO Draft EIS Comments April 13, 2020 Page 6 along the Lower Snake River. IWUA and CO9 supports the comments of the Port of Lewiston and State of Idaho relating to economic impacts.	The EIS includes extensive analysis of the effects of MO3 to navigation and transportation (Section 3.10), recreation (Section 3.11), and water supply (Section 3.12).
6411	7	paul@iwua.org	Idaho Water Users Association	C. Increased Flow Augmentation Does Not Benefit Fish. Several alternatives and, in particular, MO4 incorporate increased flow augmentation in an effort to benefit both resident and anadromous fish. The weight of the science, however, suggests that flow augmentation will not provide a meaningful benefit to anadromous fish listed under the ESA. This was confirmed by the district court in its 2005 Opinion and Order: In its report issued on February 10, 2003, entitled Review of Flow Augmentation: Update and Clarification, ISAB noted as a preliminary matter that many questions remain regarding the relationship between river flows and salmon production. In summarizing the present science on the issue, ISAB noted that the benefits to salmon of ... incremental adjustments [to flow] has not been well quantified. Id. at p. 2. ISAB then stated: A different perspective emerged from this latest review. We realize that the prevailing rationale for flow augmentation is inadequate. It is neither complete nor comprehensive. There is room for alternative	We do not interpret the 2003 ISAB report to say that increased flow augmentation does not benefit fish. The ISAB's observation that the effect of incremental flow changes on salmon and steelhead survival through the CRS is difficult to quantify, and that there are other factors to consider probably has not changed since the 2003 report. However, the state of the science and data continues to support that the flow regime in a river is important to aquatic ecosystem function and native biodiversity. Resident and anadromous fish native to the Columbia River Basin are directly affected by flow quantity, timing, duration and variability. As a result of operating the CRS, the Columbia River annual flow volume, spring peak magnitude and duration, and flow variability are generally reduced relative to the natural hydrograph. While the relationship between river flow and travel time appears to have changed with the installation of surface passage devices combined with 24 hour spill, spring peak flow timing and magnitude has been demonstrated to influence smolt transit time, and there is a relationship between smolt travel time and survival. The flow augmentation measure in MO4, McNary Flow Target was developed and proposed by cooperating agencies and was intended to decrease smolt travel time through the CRS by providing additional flow augmentation. The analysis in Chapter 3 presents the smolt travel time modeled results.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				explanations of data that have scientific justification and practical value for managing the hydrosystem for multiple uses including salmon recovery. The prevailing flow-augmentation paradigm, which asserts that in-river smolt survival will be proportionately enhanced by any amount of added water, is no longer supportable. It does not agree with information now available. (emphasis added)9 There is no information in the CRSO DEIS to suggest that the science relating to flow augmentation has changed. Furthermore, while IWUA and CO9 does not believe that mainstem flow augmentation benefits fish, any flow augmentation that does occur whether in the main stem or tributaries including headwater streams must comply with state water law.	
6430	2	trolfe@celp.org	Center for Environmental Law & Policy	The Preferred Alternative would not prevent continued ESA violations in operation of the FCSR Power System. The overarching problem with the EISs analysis is that endorses a Preferred Alternative that would ensure continuing violations of the Endangered Species Act. The Preferred Alternative is essentially a business as usual approach with slight modifications, and is not projected to significantly improve conditions for anadromous fish. If the Preferred Alternative were selected, fish populations will predictably continue to decline rather than recovering. This is inconsistent with the ESAs requirement that Federal actions not jeopardize the continued existence of listed species. The bar on jeopardizing the continued existence of a species includes both actions that reduce the likelihood of survival and those that reduce the likelihood of recovery. National Wildlife Federation v. National Marine Fisheries Service, 524 F. 3d 917, 931 (9th Cir. 2007) (NMFS I). Preservation of existing populations is not enough. Recovery of salmonid populations is a critical goal of ESA-listing and the consultation process. The most recent opinion in this long-running drama specifically disapproved NOAAs use of a trending toward recovery metric, in which any population increase at all was considered to meet the requirement for recovery. NMFS II, 184 F. Supp. 3d at 891-2. As the court correctly determined, this low level of progress leaves a substantial risk that a species will be driven into extinction by events such as a few years in which environmental conditions are unfavorable. The Preferred Alternative described here fails to even meet this deficient standard. The ranges of estimated effects on fish populations under the Preferred Alternative include no effect, or even negative effects (i.e., populations could remain steady or even decrease). As such, the Preferred Alternative provides no certainty that fish populations would be improved, or even that they would hold steady at the current levels. Simply maintaining the status quo where habitat is already degraded, and will be further degraded by a continuing action, does not meet the ESAs requirements. NMFS II, 184 F. Supp. 3d at 875. The predicted effects of climate change on streamflows and water temperatures make habitat degradation even more likely under the Preferred Alternative. The Ninth Circuit has cautioned that an agencys actions may not allow a species to have a slow slide into oblivion. NMFS I, 524 F. 3d. at 930. Given the depressed state of the Snake River stocks, failing to operate the Columbia/Snake hydropower system in a fashion that facilitates recovery is tantamount to observing that slow slide but failing to act.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. In compliance with ESA, the co-lead agencies submitted biological assessments to NMFS and USFWS (Appendix V). In this Final EIS, the Biological Opinions from NMFS and USFWS can be found in Appendix V, completing this projects ESA consultation. Based on the fish analysis Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The CSS model predicts that average Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and would average above 2% (the lower end of Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse negative unintended consequences, such as long delays of adult migrants, or total dissolved gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
6430	3	trolfe@celp.org	Center for Environmental Law & Policy	The Preferred Alternative will not provide significant benefit to Snake River ESUs. For Snake River spring/summer Chinook, modelling predicts anywhere from a 7.5% decrease to a 35% increase in Lower Granite smolt to adult returns (SAR) under the Preferred Alternative, depending on whether the LCM or CSS model is used. ESA at 7-100; Table 7-25. The LCM model predicts that Spring/summer Chinook populations in the Salmon River would decrease unless latent mortality in the ocean survival phase is decreased by at least 10%, a speculative assumption. EIS at Table 7-25. As nothing in the EIS suggests that either the CSS or LCM models is more predictive than the other, the prudent approach would be to assume that effects on these fish would be slightly negative as predicted by LCM. This result would squarely conflict with the agencies obligation to avoid increasing extinction risk. Even if both models are considered equally, the result is a range of predicted results that includes no change. In other words, even by the Action Agencies calculation, the Preferred Alternative may not allow for increase in population. For Snake River Steelhead, the Preferred Alternative is projected to result in a 28% increase in Lower Granite SAR (from 1.8 to 2.3) using the CSS model. There is apparently no data available for this population using the more conservative LCM model. But the prediction of the CSS model should not be considered without remembering that the CSS prediction for Lower Granite Chinook SAR was even higher (a 35% increase), while the LCM model predicted decreased returns. ESA at 7-103 - 7-105. The Preferred Alternative discussion makes no numerical prediction for the critically endangered Snake River sockeye populations, but notes that juvenile survival is expected to be similar to the No-Action Alternative, and posits that adult passage success might be improved by an unspecified amount.2 EIS at 7-106. Snake River Fall Chinook juvenile and adult survival is expected to be similar to the No-Action Alternative. Id. at 7-107. Overall, the Preferred Alternative would have, at most, a modest positive effect on Snake River salmon and steelhead populations. There is nothing in the Final EIS that suggests these populations chances for recovery would be improved.	The co-lead agencies concur that the comment captures the expected range of effects to Snake River stocks as predicted by CRS biological models accurately. The range in predicted benefit between the two primary modeling approaches is reflective of the uncertainty associated with magnitude of CRS induced latent mortality. This uncertainty is expected to be reduced over time through a robust adaptive management process. The framework for the adaptive management process is detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
6430	4	trolfe@celp.org	Center for Environmental Law & Policy	The Preferred Alternative will not provide significant benefit to Columbia River ESUs. Just as for the Snake River ESUs, the Preferred Alternative offers very little potential benefit over the No Action Alternative to Columbia River salmonid populations. The Preferred Alternative would not meaningfully improve the probability of recovery for Upper Columbia salmon and steelhead ESUs. This Alternative is projected to have little or no effect on down-migrating juvenile Upper Columbia Spring Chinook (a 1% increase in juvenile survival). EIS at 7-94; id. at Table 7-22. SAR for this population is predicted (by the more optimistic LCM model) to increase 7% in the absence of the hypothetical reduction in latent mortality (see Section III.C, infra). This translates to an increase in returning adults from 498 to 536 fish, still a dangerously low population size. Id. Effects on Upper Columbia Sockeye and Coho are predicted to be similar to those for Spring Chinook; that is, very little benefit to these ESUs would result. EIS at 7-94 7-96. Migration and survival of Upper Columbia Fall Chinook under the Preferred Alternative is projected to be similar to that under the No-Action Alternative. Id. at 7-97 7-98. Even less benefit to Upper Columbia Steelhead is predicted; in fact, modeling predicts a very small (.1%) decrease in juvenile survival. Modifications of the Bonneville Dam fish ladder and increased spill are postulated, without any data, to possibly increase adult survival. Effects on Middle Columbia Spring Chinook are predicted to be similar to those on the Upper Columbia ESU. 7-98. Very small (<1%) increases in juvenile survival, and unquantified possible adult survival increases are predicted. EIS at 7-99. Overall the EIS does not suggest that the Preferred Alternative would significantly improve the likelihood of recovery of these ESUs	While flow levels from upstream federal CRS dams affect upper Columbia species from the time they enter the mainstem Columbia River from their tributaries, those stocks only physically pass 4 projects which limits the CRS operational impacts to those stocks. The Preferred Alternative had the largest potential positive impact to upper Columbia River stocks compared to the No Action Alternative, or any of the Multi-Objective Alternatives. In addition to continued habitat restoration and hatchery mitigation, the operational changes in spill levels at McNary, John Day, and Bonneville Dams, combined with federal efforts to reduce predation, and decrease the effects of overwintering fallback of mid-Columbia steelhead are all expected to provide benefits compared to the No Action Alternative. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
6430	5	trolfe@celp.org	Center for Environmental Law & Policy	The Preferred Alternatives gains in fish population depend largely on the uncertain prospect of reducing latent mortality. Several sections of the EIS refer to improvements in SARs based on reductions in latent mortality. This appears to refer to mortality caused by operation of the dams, but that does not occur until juvenile fish have migrated to the ocean. The Preferred Alternative predicts real improvements in populations of several ESUs, including the Salmon River Upper Columbia Spring Chinook, only if reductions in this latent mortality are achieved. EIS at 7-88; Id. at Table 7-25. However, there is very little explanation of how this would be accomplished, and latent mortality itself is not well understood. The description of the Preferred Alternative notes that the science continues to evolve on the causal factors and magnitude of latent effects caused by passage through the EIS, and the Preferred Alternative is designed partly to provide information on this question. Id. at 7-88. Given that we do not understand the magnitude or mechanism by which latent mortality is generated, it would be imprudent to assume ANY benefit due to reduced latent mortality in predicting the effects of any given Alternative. Yet much of the improvement in salmon populations predicted under the Preferred Alternative make exactly this assumption (see, for example, Table 7-25).	The co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
6430	6	trolfe@celp.org	Center for Environmental Law & Policy	The high spill levels in the Preferred Alternative may affect latent mortality or adult migration. The Preferred Alternative would increase spill over the Snake River and Lower Columbia dams to 125% TDG for significant periods of time during the juvenile migration period. EIS at 7-33; Id. at Table 7-20. While this may assist smolts in their downstream migration, there are concerns about latent mortality associated with GBT. Indeed, this is discussed as a possible limiting factor in maintaining high spill rates in the same section that describes the higher spill regime. Final EIS at 7-33. The possibility that increased GBT from the higher spill rates may work against the hoped-for decreases in latent mortality should be addressed, because higher latent mortality rates result in a very different (and lower) prediction for SARs under the Preferred Alternative. The higher spill envisioned in the Preferred Alternative may increase fallback and mortality of migrating adults. EIS at 7-92. It is also noted that higher spill may delay adult passage at some dams by creating unfavorable tailrace hydraulic patterns such as eddies, that mask adult fish ladder attraction flow. Id. The Preferred Alternative description relies on unspecified adaptive management techniques to identify and remedy any excessive fallback and delay. Id. Not only are these adaptive management techniques unidentified, but it is unclear whether they would ultimately involve measures (such as reducing spill) that would negate the benefits of the higher spill. If so, it is inappropriate to rely on the increased spill in predicting overall SAR rates or effects on salmonid populations.3	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. This will include additional monitoring for the effects of exposure to elevated TDG and will be developed with regional input to ensure adequate monitoring is in place for various lifestages of salmonids, as well as monitoring of non-salmonid species. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
6430	7	trolfe@celp.org	Center for Environmental Law & Policy	The Preferred Alternatives business as usual approach fails to address temperature concerns for two reasons. First, it simply ignores the evidence that the dams currently lead to temperature increases that can be lethal to endangered salmon populations. For this reason alone, operating the Columbia/Snake system under the Preferred Alternative would violate the ESA. Second, it fails to address the reality of climate change, which is predicted to make existing temperature concerns even worse, further harming the Snake River salmon populations and unacceptably reducing their chances for recovery. Modelling studies conducted by EPA as part of a 2003 Draft TMDL process showed that each of the four lower Snake River dam increased temperature by as much as one degree C. U.S. Environmental Protection Agency, Columbia/Snake Rivers Temperature TMDL, Preliminary Draft (2003) (Draft TMD) at 20. EPA also found that the contribution of point sources to temperature were de minimus relative to the increases caused	The co-lead agencies agree with the commenter's concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used the best information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. Through the EIS process, the co-lead agencies developed the CRSO EIS system water quality model which consists of the 2-dimensional CE-QUAL W2 models and the 1-dimensional HEC-RAS models. In parallel, EPA has updated the RMB10 1D temperature model to assess Columbia and Snake River water temperatures and evaluate the impacts from the federal dams as part of the reinitiation of the TMDL project. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				by the dams. Id. at 39. In other words, even if all point sources on the river met water quality standards for temperature, EPAs modeling shows that the water quality standards simply cannot be met with the dams in place. See Draft TMDL at 39. This confirms that under the Preferred Alternative, lower Snake River temperatures will continue to exceed the tolerance of salmonids even under present-day climatic conditions. This in turn will reduce the likelihood of species survival or recovery. The conditions predicted to result from climate change make this factor even more important. Warming is predicted to be even more severe in the Snake River Basin than in the other basins. EIS at 4-12. Under climate change, conditions similar to the high temperature, low flow year will become more common. These are the conditions under which the highest number of days with water temperature exceeding 68 degrees F currently occur. See EIS, App. D at 3-26; Id. at Figs. 3-12 and 3-13. More frequent low summer flows would be expected to increase summer water temperatures over those presently seen, which will result in even more difficult conditions for salmonids than are currently existing.	The co-lead agencies' results show that breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3. Predicted water temperatures under MO3, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. In EPA's Draft Total Maximum Daily Load (TMDL) for Temperature in the Columbia and Lower Snake Rivers (2020), the TMDL accurately states that even if all the allocations in the TMDL are implemented and temperature reductions are fully realized, it is unlikely that the numeric criteria portion of the WQS will be met at all times and all places. In fact, EPA recommends that the States of Oregon and Washington make changes to their applicable designated uses, as part of a use attainability analysis. The existence of the dams, as operated for the congressionally authorized project purposes, contribute to a shift in the natural water temperature regime in the Columbia and Snake Rivers, creating cooler than natural conditions in the spring and early summer and slightly warmer conditions during the fall and winter months, but the co-lead agencies also recognize that historical water temperatures in the Lower Columbia River, before major development of dams, frequently exceeded the current numerical standard of 20C during the summer months. Factors, such as global warming, may also contribute to water temperature exceedances in the future. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4).
6430	8	trolfe@celp.org	Center for Environmental Law & Policy	The only Alternative that significantly improves water temperature is dam breaching (MO3). Consistent with EPAs findings (see Draft TMDL), the only Alternative that significantly reduces Lower Snake River water temperatures is the dam breach scenario (MO3). See EIS, App. D at 6-25 - 6-38. Under this Alternative, the amount of time in which water temperatures would exceed the 68 Deg. Fahrenheit threshold at the lower three Snake river dams would decrease significantly. Id. at Table 6-1. Even for the extreme low flow/high temperature conditions experienced in 2015, a computer modeling study showed that had the four lower Snake River dams not been in place, water temperatures would have been below the threshold for all but very short periods of the summer if the four lower Snake River dams had not been present. Schultz at 4. In contrast, under the Preferred Alternative lower Snake River water temperatures would be similar to the No-Action Alternative. EIS at 7-84.	The co-lead agencies agree with the commenter's concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used the best information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. Breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3. Predicted water temperatures under MO3, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. Overall the conclusion in the Draft EIS is that MO3 would be beneficial to anadromous fish for a number of reasons, but other objectives must also be considered in the selection of a Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3. However, the Preferred Alternative also meets all the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. The dam breaching alternative, by contrast, has significant regional economic impacts and community effects, and meet only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6430	9	trolfe@celp.org	Center for Environmental Law & Policy	Comparison of alternatives is prejudiced by including anti-predation measures to improve survival in the Preferred Alternative but not MO3. Regulating water level to reduce predation in John Day Reservoir (this measure is expected to improve success of down-migrating smolts) was omitted from the dam breaching Alternative but included in the Preferred Alternative. No reason is provided for this decision, which serves to improve survival in the Preferred Alternative but not in MO3. To facilitate a fair comparison, predation reduction should have been considered with the dam breaching alternative as well. As this measure (and its effects) are presumably independent of whether the Snake River dams remain in place, this consideration should be a straightforward exercise. Such selective inclusion of individual components serves to artificially increase the perceived likelihood of success for the Preferred Alternative relative to the dam breaching alternative, and frustrates the ability to evaluate the merits of dam removal in an apples-to-apples manner.	Ongoing avian predation measures would continue under MO3 similar to No Action Alternative to manipulate avian habitat on the Columbia and Snake Rivers. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Therefore, adding the Predator Disruption Operation measure to MO3 would not alleviate the regional economic and community effects, nor would it cause MO3 to meet more EIS objectives than without the measure's inclusion. The co-lead agencies did not recommend MO3, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system than MO3.
6430	10	trolfe@celp.org	Center for Environmental Law & Policy	Comparison of alternatives is prejudiced by including hatchery closures under MO3 but not the Preferred Alternative. The Snake River hatcheries would remain operational in all Multiple Objective Alternatives except MO3 (dam breaching). EIS at 2-37. The Preferred Alternative also does not appear to include closure of Snake River hatcheries. Hatchery fish make up a substantial fraction of those returning to the Lower Snake river, although it is unclear exactly what fraction of Snake River hatchery fish are produced by hatcheries that would be closed. Logically, loss of hatchery fish in MO3 would result in apparently lower numbers of returning fish, which would led to understatement of the improvement in populations achieved through dam breaching. This would tend to bias the predicted effect of dam breaching on fish populations downward (put another way, the numbers of Snake River returnees under MO3 would be expected to be even higher if the hatchery production were maintained). The overall effect of this would be to understate the improvement in fish populations achieved through dam breaching vs. the Preferred Alternative.	The Draft EIS acknowledges that with breaching of the Snake River dams in MO3, there would no longer be an obligation to fund the Lower Snake River Compensation Plan, which accounts for much of the hatchery production in the basin, other mitigation activities could be adjusted, and transportation of Snake River salmon and steelhead would no longer be possible. The rationale for this, as stated in the Draft EIS, is that Bonneville's funding is directly tied to the operation of the LSR dams. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. As stated on page 3-548, the co-lead agencies recognize there would be transitional needs that would be addressed through mitigation and adaptive management. The fish models are based upon data collected from past fish runs and there is no data available to inform an quantitative analysis for wild fish in the absence of hatchery fish. The co-lead agencies took a qualitative approach to inform the reader of other factors that could affect salmon but acknowledged the magnitude of those effects is not known. A summary of this qualitative discussion is provided for the reader for each Snake River species. The analyses used in this Draft EIS were for the purposes of comparing the effects of the action alternatives for operation, maintenance, and configuration of the CRS projects to one another and to the No Action Alternative. Hatchery programs are discussed briefly in the Affected Environment to give the reader the general information on hatchery programs that are a part of the ESU/DPS described.
6430	11	trolfe@celp.org	Center for Environmental Law & Policy	Dam Breaching is economically feasible. The ESAs argument against the dam breaching alternative (MO3) is largely economic, based on the projected costs of replacing the generating capacity from the four lower Snake River dams. However, the EIS shows that the total annualized cost of MO3 is actually lower than the No- Action Alternative, or any of the other Multiple Objective Alternatives. See EIS at Table 3-1. Nothing in the EIS suggests that, absent a court Order requiring a new EIS, anything other than business-as-usual (essentially, the No-Action Alternative) would have occurred. If operating the system under the No-Action Alternative is economically feasible, then it follows that the dam breaching strategy is also economically feasible.	This comment appears to be referencing the total annual equivalent cost estimates presented in Table 3-1 (final row of Table 3-1, at page 3-11 of draft EIS). While the comment is consistent with the EIS that these costs are lower under Multiple Objective (MO) Alternative 3 (which includes breaching the four lower Snake River dams) than the No Action Alternative, these costs solely reflect the costs of the structural and operational costs of the Columbia River System, including fish and wildlife spending analyzed in the Implementation and System Cost Analysis (Section 3.19). These costs do not represent the full set of economic costs and benefits analyzed in the EIS, such as effects on navigation, water supply, or power generation, and thus do not represent the economic feasibility of any alternative. In the context of power for example, the annual equivalent costs do not include the costs of resources needed to replace lost generating capacity from the four lower Snake River dams. These other effects for each alternative are described elsewhere in Table 3-1. A footnote for Table 3-1 in the final EIS clarifies that the last row only represents direct costs. In response to this and other comments, Chapter 7, Table 7-56 in the final EIS summarizes all of the socioeconomic effects of the alternatives.
6430	12	trolfe@celp.org	Center for Environmental Law & Policy	All evidence and experience points to the conclusion that the dams are the problem for Snake River salmonids. Indeed, the Preface to the EIS notes that even after tremendous effort and billions of dollars expended to improve fish habitat and passage, the dams have a major effect on the fish populations. Judge Simons 2016 Opinion discussed the possibility that a new EIS might lead to innovative new solutions, but the this EIS and its Preferred Alternative falls far short of that goal. This document is clearly designed to provide support for continuing the status quo and avoiding any real consideration of breaching the lower Snake River dams. The No-Action Alternative was rejected because it did not meet the objectives of improving salmonid populations. However, the information in the EIS demonstrates that the Preferred Alternative is not significantly better in this regard. The Preferred Alternative, too, should be rejected. Evidence presented in the EIS squarely shows that dam breaching is the only strategy that significantly improves chances of recovery for the Snake River salmonid ESUs. The ESU also demonstrates that dam breaching is feasible. From the standpoint of preventing further ESA violations, MO3 is the only acceptable alternative. Because of the tremendous amount of evidence showing that dam breaching is the only alternative that will result in recovery of the Snake River fish populations, and the absence of evidence demonstrating that the Preferred Alternative is reasonable, a decision adopting the Preferred Alternative would be arbitrary and capricious. Such a decision would fail to give the benefit of the doubt to the endangered species and would fail to comply with the ESA.	As required by NEPAs implementing regulations, the co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the alternative that includes the measure to breach the lower Snake River dams. However, the Preferred Alternative also meets the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. The alternative that includes the measure to breach the lower Snake River dams, by contrast, has significant regional economic impacts and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend that alternative (MO3) because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6433	1	jeps3448@gmail.com	N/A	Maintaining the river system for barging is critical both to my farming operation and thousands of other farmers, their families, and employees, across the Pacific Northwest. Because of the locks and dams on the river I am able to ship efficiently and in a cost effective manner, my crop to ports of export. If this system were impaired I see several negative, far reaching impacts. Most directly it would cost at least double to deliver my wheat to market, which would have a major impact on a bottom line that already has a relatively thin profit margin. Moreover, the loss of barge traffic if dams were breached could require as many as 100,000 more semis to haul both grain and other goods up and down the highways. For five years I lived in Boardman, Oregon on the I-84 corridor. During this time I saw a noticeable uptick in truck traffic on the freeway. This was with the barges running as normal. If barge traffic were decreased or eliminated our rural freeway could soon look like I-5 running through Portland. Of course, there is already a shortage of trucking capacity in the region, so it's unclear how farmers such as myself would even find the logistic resources to ship our products to market. Other items such as fuel and fertilizer would also cost more to deliver to our region. I fear any breaching of dams could have ripple effects that would simply put a lot of people like myself out of business. Provided trucks and rail could be found, they would have a profoundly negative impact on our air quality. Barges are 270% more efficient than semi-trucks. All the additional trucks, along with trains, would generate an estimated 1.2 million tons of additional CO2 annually. This, combined with a loss of clean power generated by the dams, is absolutely counterproductive to our general goals of reducing greenhouse gas emissions.	The EIS recognizes that under a dam breach scenario, transportation costs for farmers would increase. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the furthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most negatively impacted. Cost scenarios for example farming operations are presented in the Regional Economic Effects section in section 3.10.3.5. The EIS recognizes that, faced with increasing transportation costs, profitability of farming in this region would be adversely affected. In general, wheat producers are price takers, so keeping production costs lower are critical for remaining competitive. The EIS also acknowledges that, depending on the scenario, truck ton-miles may experience an increase of 19 percent (under Scenario 1, when rail rates are not assumed to increase) to 84 percent (when rail rates increase by 50 percent) under MO3 when compared to the No Action Alternative. The EIS found that truck trips could increase from an additional 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region.
6435	1	dlparks398@gmail.com	N/A	It has been suggested that the Snake River Dams have produced positive economic effects in the Snake River subregion of the dams. There is no convincing data to support that we cannot live without these salmon killing dams. There has been no apparent growth boom in either the farming sector or the economies as a whole in the six counties of SE Washington (Asotin, Columbia, Franklin, Garfield, Whitman, and Walla Walla) and in New Perce County in Idaho. In the 6 counties of SE WA, farm employment has shrunk in absolute terms since 1976. Farm proprietary income as a per cent of total farm earnings has decline since 1973, even though farm income has grown. While population growth in these counties has out paced the U.S. as a whole, per capita income and pay per job have have lagged national performance. Similar trends exist in New Perce County. The dams have done little or nothing for the general economic situation, while the harm to salmon is well documented. What ever the economic negatives may be from dam removal, this study needs to revised and identify these and then develop an alternative that both removes the dams and makes local populations and economies whole	Thank you for your comment. There are benefits and costs associated with operating the lower Snake River projects. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes the dam breaching measure. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
6447	1	gary@mtco-ops.com	N/A	From our associations perspective, it makes no sense to remove this vital source of carbon-free generation. By one reliable estimate, breaching the Lower Snake River Dams would be the equivalent of putting 421,000 carbon-emitting vehicles on the highways of the Pacific Northwest. It is important a reasonable balance be struck and we believe the preferred alternative strikes the right balance. As stated in our oral testimony on March 25, we cannot ignore the serious challenges facing our region in terms of both salmon protection and maintaining a clean, affordable power system.	The comment that breaching the four lower Snake River dams would increase greenhouse gas emissions from power generation and transportation is consistent with the findings of the EIS. Even if the four lower Snake River dams were breached and replaced with new variable renewable resources, the EIS found that greenhouse gas emissions would increase because existing fossil-fuel fired power plants would run more often . Draft EIS, Section 3.8.3.5, 3-1009-1010.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6447	2	gary@mtco-ops.com	N/A	We understand the need to help salmon because they do need our help. This is true up and down the Pacific Coast. Salmon and Steelhead in river systems both with dams and without dams are struggling. It is absolutely clear to us the salmon issue is much bigger than the future of the lower Snake River dams. Narrowly framing the challenge as a Hydropower problem ignores key issues associated with Harvest, Hatcheries, Habitat, Ocean Conditions and Predation.	There are many effects to salmon and steelhead populations outside the operation and maintenance of the dams (see Chapters 6 and 7 for more information). Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. While none of the Multiple Objective alternatives would affect ocean conditions or directly impact tributary habitat conditions, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of these environments in the return of adult salmon and steelhead. Many of the types of habitat improvement actions implemented by the co-lead agencies in cooperation with regional stakeholders can provide improved conditions for many fish species. Habitat mitigation program descriptions are discussed briefly in the No Action Alternative in Section 3.5.3.3 to give the reader the general information on these programs. Chapter 7 describes programs that would continue as well as new mitigation under the Preferred Alternative. Hatchery programs have long been a part of the approach for salmon recovery. Based on our analysis of fish resources in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery operations are proposed.
6447	3	gary@mtco-ops.com	N/A	We also cannot ignore the fact that we absolutely have to maintain a dependable Power System. Can you imagine our communities throughout Montana, the Northwest and the United States right now trying to address COVID-19, the biggest public health crisis of our lifetimes, without reliable electric power? This illustrates why dam-breaching must be rejected as an option to assist salmon recovery. More than doubling the risk of blackouts in the Northwest is absolutely unacceptable! The Draft EIS shows that the cost of replacing the clean energy benefits provided by the lower Snake River dams would add $1 billion annually to electricity costs. Doing this without impacting reliability would require replacing the dams with fossil fuel generation. For millions of people across the Northwest, this would result in a 25 percent increase to their monthly electric bills. Many vulnerable communities are struggling to make ends meet. We already have an affordable housing shortage and a homelessness crisis and extreme measures like dam breaching would make these problems much worse. At our co-ops across Montana, we expect that the local impact of the coronavirus crisis will become much worse in the days, weeks and months ahead. We cannot pretend that a 25 percent rate increase is something that our members will be able to afford. In closing, Montana Electric Cooperatives Association believes salmon do need our help but we also believe strongly that the lower Snake River dams are absolutely critical to our region.	The comments that breaching the four lower Snake River dams would (a) increase the frequency of power shortages unless and until replacement resources were built, and (b) would result in increased costs in the region, are both consistent with EIS findings. See EIS, section 3.7.3.5, Table 3-166; see also Appendix H, Table 2-1. The EIS also finds that Bonneville customers, such as cooperatives mentioned by the commenter, may be more directly affected by rate pressures than other regional utilities that do not purchase power directly from Bonneville. See EIS, section 3.7.3.5, Residential Effects, 3-929. The Environmental Justice analysis (Section 3.18.3 of the EIS) provides further detail on potential disproportionate effects including to tribal, low-income and minority populations. Chapter 5 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers.
6463	1	none provided no provided	Riggins, Stanley, Salmon, White Bird, and Kamiah Chambers of Commerce	I. The draft EIS does not adequately evaluate economic impacts of the Northwest salmon and steelhead fishing industry. The draft EIS fails to consider the economic impacts of the Northwests salmon and steelhead fishing industry. When evaluating the economic impacts of each alternative, the analysis completely ignored the sportfishing economy and its estimated contribution of over $757 million in Idaho alone (over $2 billion region-wide). 2 Table 1: Summary of Regional and Other Social Effects. The agencies analysis of regional and other social effects is shown in Table 1 above. The draft EIS relied solely on a qualitative, rather than quantitative analysis to evaluate impacts despite the existence of several current studies on the economic contributions of outdoor recreation and sportfishing in states with anadromous fish. This contrasts with analyses of water supply, irrigation, navigation, and hydropower generation, which were all evaluated quantitatively. At the March 5, 2020 Idaho Governors Salmon Workgroup meeting, an Army Corps of Engineer economist stated economic impacts of sportfishing were outside the scope of the EIS, despite all other resources evaluated in the analysis including quantified effects. Our collective region is overwhelmingly rural and heavily dependent on natural resource and recreational based economies. In 2001, the Spring Chinook season brought $10 million to Riggins alone, where the total spending that year was $44 million1. In the same thread, during the four-month steelhead fishing closure on the Clearwater River in 2019, the Clearwater Region missed out on $8.6 million a month ($34.4 million total), with the majority of the loss in Clearwater County2. It is unacceptable that the draft EIS did not include publicly-available data sources to quantify both the economic potential of abundant fish returns as well as the devastating financial impacts of declining salmon and steelhead populations on rural communities in Idaho and throughout the Pacific Northwest. 1 Economic data sourced from Jim Fredericks, Idaho Department of Fish & Game, Governors Salmon Workgroup Meeting. June 28, 2019. Unpublished. 2 Economic data sourced from Kathryn Tacke, Idaho Department of Labor. Unpublished. 3	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
6463	2	none provided no provided	Riggins, Stanley, Salmon, White Bird, and Kamiah Chambers of Commerce	II. The Preferred Alternative does not result in future salmon and steelhead returns necessary for harvest or recovery. The Preferred Alternative in the draft EIS does not adequately provide for salmon and steelhead population recovery because it will not improve smolt to adult turn rates (SARs) to levels identified by scientists, the Northwest Power Council, and the Columbia Basin Partnership as necessary for harvest or recovery. Harvestable populations require consistent SARs of around 4%3. Under the Preferred Alternative shown in Table 2 below, SARs for Snake River Spring Chinook will reach 2.7% at best. The predicted SAR under the Preferred Alternative, shown in Table 3, is even lower for Snake River steelhead at 2.4%. At worst, the Life Cycle Model predicts an extinction trajectory under the Preferred Alternative with a SAR below 1%, with Snake River spring Chinook SARs predicted at a troubling 0.81%. The draft EIS and the range of alternatives analyzes SARs for natural and hatchery origin fish together, rather than as separate stocks. It is troubling that this analysis does not even strive to meet the natural origin stocks SAR that is required to meet and surpass delisting criteria under the ESA. We believe the alternative should benefit and strike a balance that all users throughout the system can support, but our Chambers, communities and members cannot support implementation of river system operations that may contribute to the extinction of salmon and steelhead that we heavily rely on. Table 2: Summary of predicted annual SARs for Snake River spring Chinook, evaluated by two models. 3 Northwest Power and Conservation Council. 2014. Columbia River Basin Fish and Wildlife Program. pp. 29. https://www.nwcouncil.org/sites/default/files/2014-12_1.pdf 4 Table 3: Summary of predicted annual SARs for Snake River steelhead, evaluated by two models	The Smolt-to-Adult return (SAR) target of 4% referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on our analysis of the Preferred Alternative, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead which is within the Councils targeted range for recovery. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
6463	3	none provided no provided	Riggins, Stanley, Salmon, White Bird, and Kamiah Chambers of Commerce	III. The dEIS 45-day open comment period does not appropriately engage all affected parties with the threats of COVID-19 pandemic in our communities. Our rural towns are feeling the very real threat of the COVID-19 outbreak and are currently focused on the health of our community members. Many business owners in our membership have been forced to shut their doors to implement prevention measures during these trying times. For many of our members, the COVID-19 outbreak is one more devastating blow after two years of reduced fishing season. We believe a 45-day comment period and conference call meetings severely limited the engagement of all regional stakeholders on this critically important guiding framework.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
6464	1	richardvinh@lclark.edu	Northwest Environmental Defense Center	This comment is submitted on the behalf of the Northwest Environmental Defense Center. Thank you for your consideration. Please see attached comment.	Unfortunately, an attachment was not received from the commenter. The co-lead agencies requested the commenter resubmit via e-mail on June 25, 2020; however, the co-lead agencies did not receive a response to this request.
6467	1	N/A	N/A	EWEB receives 70 percent of its electricity from the Bonneville Power Administration (BPA). Each year, EWEB supplies on average 4.5 million megawatt-hours of electricity to customers. Prior to 2028, EWEB will need to reassemble a power generation portfolio, renewing or replacing over three quarters of the resources currently utilized, including EWEBs contract with BPA, and the Carmen-Smith hydro facility relicensing project requiring an additional $115 million investment.	The comment refers to Bonneville contracts ending in 2028 as well as other utility specific concerns. The EIS did not evaluate specific utilities and their investment decisions; however, the EIS does acknowledge competitive pressure and changes in the regional power market in Sections 3.7.2.5, pages 3-801-802 and Section 3.7.3.1, at pages 3-842-843 of the Draft EIS.
6467	2	N/A	N/A	Several public comments have suggested that BPA sells power at a loss, or that BPA is close to becoming financially insolvent. Both are inaccurate. EWEB recognizes that structural changes in electricity markets over the last decade have resulted in persistent low wholesale power prices, impacting the secondary revenues BPA receives from the sale of surplus clean energy. However, EWEB believes that BPA has made significant changes to adapt to this new paradigm, and evidence suggests that BPA is in the process of bending its cost curve towards a future in which they will remain the supplier of choice. In EWEBs judgment, although wholesale market prices are depressed in recent times, BPA rarely sells its surplus electricity for less than it costs to generate. Furthermore, as the Western US continues to adopt policies to reduce GHG emissions, including carbon pricing, it is EWEBs view that hydropower will be recognized for its positive environmental attributes, and also for its inherent operational characteristics such as flexibility and reliability, thus improving BPAs secondary revenues over time. When these externalities are accounted for in our energy future, hydropowers economic value will be greater than it is today.	The comment notes many strategic changes Bonneville has made regarding competition in the power market. Consistent with the observations, the BP-20 rate case marked an important milestone in Bonneville's implementation of its Strategic Plan. The power rate increase was zero percent. BP-18s rate increase was below the rate of inflation. Over the last four years, Bonneville has fundamentally changed course due to principled cost management. The comment about the economic value of hydropower is consistent with information presented in the EIS. For additional discussion of Bonneville competitiveness, see Sections 3.7.2.5, pages 3-801-802 in the Draft EIS and Section 3.7.3.1, at pages 3-842-843 in the Draft EIS.
6467	3	N/A	N/A	It has also been suggested that role of the Snake River Dams in regional resource adequacy has been overestimated. That is also inaccurate. In the long term it is possible that the Dams may not be needed for resource adequacy because suitable replacement generation or additional inter-regional transmission and transfer capability can eventually be constructed to replace them. However, in the near- to mid- term, the flexibility and dispatchability of the Snake River Dams play a crucial role in regional reliability. It is a simple fact that the Pacific Northwest is still a winter peaking region; from October to March, the Snake River Dams often provide more than 2000 megawatts of clean electricity, as well as roughly one quarter of the entire federal systems reserves capability, precisely when it is needed most.	The statements that the four lower Snake River dams are important for regional power reliability and offer peaking capability are consistent with the findings and discussions of the EIS. See Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907 in the draft EIS.
6475	1	debi.wilson@laneelectric.com	N/A	Cautious support for the Preferred Alternative (PA) proposed by the co-lead agencies. We support the flexible spill concept adopted by the co-lead agencies in the PA. However, we are concerned about unprecedented and untested spill to 125% Total Dissolved Gas (TDG), and its impact on Endangered Species Act-listed salmon species. In the absence of clear science around the impacts of spill to these federally protected fish, we insist on	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				robust safeguards (see next bullet). Support for fishery monitoring and adaptive management. We support the development of a robust approach to monitoring to determine how fish respond to new and significantly increased levels of spill. We also encourage the co-lead agencies to develop and improve upon an adaptive management framework to protect listed species from unintended consequences that may arise due to operations that utilize enhanced spill	The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
6475	2	debi.wilson@laneelectric.com	N/A	Support for further study regarding the socio-economic impacts of blackouts. We intuitively know that blackouts have a substantial ripple effect on communities, especially in terms of their impact on human health and welfare and economic prosperity. Almost 80% of Lane Electrics load serves rural residential members. When these members have no electricity, they also have no water because they depend on electric pumps for their wells. This is an area that could benefit from further analysis in the context of this EIS. We encourage the co-lead agencies to sharpen the analysis around the socio-economic impacts of blackouts prior to issuance of the Record of Decision.	The commenter is correct that there could be socioeconomic effects if blackouts occur. The EIS methodology includes the full incremental replacement resource cost necessary to return the region to a level where the likelihood of blackouts is equal among all the alternatives, such that comparisons can be made among the alternatives on an equal basis. The EIS assumes for each Multiple Objective alternative (MO) that sufficient resources are acquired to reduce the risk of blackouts to the level of risk that existed prior to implementation of the MO. Once replacement resources have been acquired, the risk of a blackout for each MO is effectively the same as the No Action Alternative. The EIS evaluates the costs of replacement resource portfolios that would be required to avoid increasing the risk of an outage. See Draft EIS, Section 3.7. The approach in the analysis is to first evaluate the increased risk of power outages related to an alternative, and then identify what resources are needed to avoid that increased risk of an outage. Thus instead of identifying the potential socio-economic costs of power shortage, the analysis identifies the costs of replacement resource portfolios that would be required in order to avoid increasing the risk of an outage. If the EIS had then also added to each MO the additional cost of a blackout, then the MOs would have double-counted the impact of blackout risk (i.e. the MOs would have included the cost of avoiding blackouts and the costs of blackouts). The analysis identifies that the expected outcomes of MO3 and Multiple Objective alternative 4 (MO4) would be an increase in the cost of power and not in the risk of an outage. See Draft EIS, Sections 3.7.3.5 (MO3) and 3.7.3.6 (MO4). Because of the shape of the remaining hydropower generation in the Preferred Alternative, the loss of load probability was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary.
6485	1	johns944@wwu.edu	N/A	This draft EIS fails to adequately address these values and concerns. The Endangered Species Act mandates that implicated agencies restore populations of an endangered species in all or a significant portion of the species range. Despite about $300 million spent annually on mitigation efforts to raise fish populations, wild salmon and steelhead populations in the Columbia system remain critically low. Most of the Snake River salmon and steelhead runs listed under the ESA are currently at around 1% of historic levels. Restoring anadromous salmonids to the whole Columbia system isnt feasible, or within the jurisdiction of the implicated agencies. However, significant improvements to populations of these fish are very possible in the Snake tributaries between Hells Canyon and Lower Granite. This region of the Snake contains hundreds of miles of pristine, undammed tributaries, including the Salmon, Clearwater, and others. Therefore, the co-lead agencies have a legal responsibility to restore populations to these tributaries. The Northwest Power Act is also of particular relevance to the actions of the co-lead agencies. This act directs the Administrator and other federal agencies responsible for managing, operating or regulating hydroelectric facilities on the Columbia River or its tributaries to provide equitable treatment for fish and wildlife in comparison with the other purposes of the facilities and take the [Northwest Power and Conservation Councils] program into account as much as possible at each stage of decision-making. The various stopgap mitigation programs that, again, cost about $300 million per year have not helped wild anadromous fish populations in any significant way. Salmon are not just a human food source. They feed over a hundred other species, and they are a critical link in Pacific Northwest ecology, transporting a massive amount of marine-derived nutrients upstream to feed our forests. Clearly, fish and wildlife are not getting a good deal out of current use of the Columbia River System.	Recovery efforts referenced in this comment and references to the Northwest Power and Conservation Council(Council) fish and wildlife program with associated target for broad-sense recovery are separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the analysis of the Preferred Alternative, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies used current high quality information and the best available scientific information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The agencies provide equitable treatment on a systemwide basis primarily by implementing hydrosystem management and operations identified in relevant NMFS and USFWS biological opinions, in the Columbia Basin Fish Accord agreements, and in measures included in the Northwest Power and Conservation Councils fish and wildlife program. On a systemwide basis, the co-lead agencies ongoing management of the CRS will continue to provide fish and wildlife equitable treatment with the other authorized purposes of the system.
6485	2	johns944@wwu.edu	N/A	On the other hand, the Columbia system is the most dammed river system in the world, and this EIS demonstrates the premium placed by the co-lead agencies on power generation, among other direct human services. Especially given the minimal role that the LSRDs play in our modern energy system, this treatment does not strike me as equitable. Before dams were put in place in the Columbia and Snake, juvenile salmon could travel from the headwaters of the Salmon River to the sea in about 10 days. Instead of swimming, they primarily rode the downstream flow, and their physiological transition for living in saltwater was timed for this short journey. With the dams in place, a large portion of juvenile salmon mortality occurs in the reservoirs, where slacker water forces them to expend energy, warmer water causes physiological problems, and predatory fish are more plentiful. Though predator control has been used, most of the mitigation efforts to reduce juvenile mortality are aimed simply at getting them past the dams themselves. The effect of reservoirs on salmon populations must be addressed explicitly in the alternatives considered in this EIS.	In its analysis of effects, the Draft EIS used current high quality data and best science, including models and studies published in peer review science journals. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. This analysis includes the effects of migrating through the reservoirs. Under the Preferred Alternative, Snake River Chinook juveniles will migrate from Lower Granite to Bonneville Dam in about 16 days. Efforts to reduce predation from pinnipeds, avian, and fish will continue under the Preferred Alternative, with the additional benefits expected from the Predator Disruption Operations measure. Regarding the power system, the commenters statements are inconsistent with the findings in the EIS. Specifically, the four lower Snake River dams produce upwards of 1,100 aMW of power, which is approximately 13 percent of the average power produced by the FCRPS. See EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. This amount of lost power is equivalent to the amount of power used to serve 900,000 homes in the Pacific Northwest. See EIS Section 3.7.3.5, Summary of Effect, at 9-935. To maintain regional reliability at the No Action Alternative levels, the EIS found that additional resources would be needed. See EIS Section 3.7.3.5, Potential Replacement Resources and Associated Costs, at 3-904-910.
6485	3	johns944@wwu.edu	N/A	The preferred alternative largely sticks to the status quo, continuing use of increased spill and similar measures. The same is true of all multiple objective alternatives listed, outside of MO3. The status quo clearly is not working. The preferred alternative claims to meet the improve juvenile salmon and improve adult salmon objectives. However, the best-case model output for Snake River Chinook and steelhead in the preferred alternative gives SAR increases of 35% and 28%, respectively. A 35% improvement on 1% of historic levels yields 1.35% of historic levels, which is not good enough. Under this model result, the co-lead agencies will not be fulfilling their legal duties under the ESA and the NPA. Breaching the LSRDs is the only alternative addressed that would lead to a major increase in salmon and steelhead populations. To assess the effectiveness of MO3, this draft EIS uses SARs from both the CSS model and NOAAs LCM model. However, the SARs from NOAAs LCM model only measure the percentage of fish that return from Lower Granite to Bonneville. This measure underestimates the increase in return percentage under dam breaching, since return of adults through the lower Snake is not considered; with the dams breached, lower adult mortality would be expected in this region. Furthermore, the LCM model suggests that juvenile latent mortality due to the dams could drop anywhere from 0% to 50% in the breaching scenario, with 0% as the default. While I assume that this model is factoring in a drop in mortality due to a shorter run-time (5.5 days shorter for Snake River Chinook according to table 3-85), setting a dam-related latent mortality drop of 0% from dam breaching is still unreasonable. If juveniles are passing through 4 fewer overheated reservoirs that require extra physical exertion, latent mortality from dams themselves should decrease. For these reasons, the LCM fish model under the breaching scenario underestimates the increase in Snake River salmon and steelhead population relative to other alternatives. This underestimate creates bias against MO3. The co-lead agencies must correct this bias.	The flexible spill operation in the Preferred Alternative was implemented for the first time in 2019, and active monitoring will be used to inform an adaptive management process as described in Appendix R. The commenter is correct that spill and many other measures considered in the MOs have been implemented in the last couple decades, which has provided data regarding effectiveness. In combination with hatchery supplementation and habitat restoration, adult abundances of most of the salmon ESUs in the Columbia Basin have been trending upwards in the last 20 years, although hatchery origin adults now make up a large component of many stocks. Certain wild ESUs such as Snake River fall Chinook have had a much more positive trend in recent years than other ESUs in the basin, despite their average SAR near the 1% range. High freshwater productivity rates in the early juvenile stages were necessary for this to occur. The NMFS and CSS Life Cycle models (which are both only able to model Snake River spring/summer Chinook) are able to incorporate spawner capacity and density effects in the juvenile stages, in addition to outmigration through the CRS and SAR. For the 2000 Biological Opinion, NOAA proposed estimating free-flowing Snake River survival rates by estimating survival rates of PIT-tagged smolts from both the Salmon River trap, and from the Snake River trap (at the head of Lower Granite Reservoir) to the Lower Granite bypass. The per-kilometer survival rate of the free-flowing portion of the Snake River could be inferred from these difference between these two trap-to-dam estimates (Ferguson et al (2004). For the CRSO EIS, NMFS used a similar method of estimating free-flowing survivals and travel times with their COMPASS model. PIT-based monitoring efforts have occurred at 20-plus additional hatchery and wild trap locations in the Snake and upper Columbia since the 2000 BiOp. In the appendix, NMFS carries out a sensitivity analysis for the choice of upstream trap location by comparing free-flowing survival rates estimates from the Grande Ronde, Salmon, and Imnaha traps to Lower Granite Dam to represent dam breach conditions under alternative MO3. There is a wide variance in per-kilometer travel times and survival rates to Lower Granite Dam among all of the possible hatchery release sites and screw trap locations upstream of Lower Granite Dam. The river conditions and migration behavior of fish in tributaries to the Snake River is much less representative of river conditions we expect in the Lower Snake river following dam breaching than are the river conditions in the free-flowing Snake River between the confluence of the Clearwater River and the confluence of the Salmon River. NMFS selected the three locations because each trap location was low in the tributary and are very close to the mainstem Snake River; we expect that reach of the free-flowing Snake to be very similar to what the breached lower Snake would look like in MO3. Ferguson J. (2004) Memorandum to FCRPS biological Opinion Remand Administrative Record RE: Updated estimates of free-flowing river survival. NW Fisheries Science Center.
6485	4	johns944@wwu.edu	N/A	Another downside brought up for the MO3 alternative is that reductions in hatchery fish could reduce numbers of juvenile Snake River Chinook salmon by as much as 85 percent. Hatcheries have long been used as a crutch to maintain salmon populations and mitigate the effects of dams. However, the ESA mandates that the agencies restore wild populations. While hatchery fish may reduce predation rate on wild fish by increasing sheer numbers, they also compete with wild fish. The science is quite clear that hatchery salmon are less fit than wild salmon and simply cause further harm to wild salmon populations. A resilient ecosystem requires genetically diverse salmon populations with high fitness levels. If the co-lead agencies are to follow the ESA, the goal should be to reduce reliance on hatcheries, even if total salmon passage is initially reduced.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. Hatchery programs have long been a part of the approach for salmon recovery. Based on our analysis of fish resources in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery operations are proposed. The listings of ESUs/DPSs often include fish produced in hatcheries. Hatchery origin fish are very important to Tribal and sport harvest in within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the three co-lead agencies have legal requirement to produce hatchery fish as mitigation for components of the CRS. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act.
6485	5	johns944@wwu.edu	N/A	A final form of bias that this EIS demonstrates for all salmon and steelhead populations considered is that it does not factor in climate change. Regardless of regional greenhouse gas emissions, climate change is baked into our current world order; it is happening, and it will continue to happen. Salmonids, like most species, face adverse effects from climate change. Dr. Erika Eliasons work on how increased water temperature affects Fraser River sockeye physiology is a good example. Without factoring in climate change, all population estimates of these species are overestimates. The ESA does not give anyone a pass on considering the impacts of climate change. Therefore, climate change creates an even stronger imperative for the co-lead agencies to move beyond the status quo in salmon conservation.	Regarding climate change, the climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change and, unfortunately, they have not been fully applied and validated for use with climate affected regulated flow projections for large reservoir systems. Therefore it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3). Additionally, in the cumulative effects chapter (Section 6.3.1), climate change is analyzed as one of the reasonably foreseeable future effects relevant to anadromous fish. This information is summarized in Table 6-19.
6485	6	johns944@wwu.edu	N/A	This EIS also fails to consider the southern resident orca as an affected endangered species. While it is clear that southern resident orcas do not physically reside in the Columbia River Basin, it is just as clear that the Columbia system plays a crucial role in their health. Southern resident orcas are starving to death. 80% of their diet is salmon, of which the vast majority are Chinook, and they preferentially feed on larger size classes. Todays southern residents are visibly emaciated. Lack of food leaves them particularly vulnerable to noise pollution (which makes scarce food even harder to hunt) and chemical pollution (fat soluble chemicals like PCBs are more likely to be transferred from mother to baby when the mother is starving). A small number of breeding adults also means that inbreeding depression is a growing concern. While southern resident orcas are struggling, transient orcas are thriving. These marine mammal-eaters feed even higher on the food chain and thus accumulate even higher levels of chemical pollutants. The difference is that they have a reliable food source. The Columbia system once provided more salmon than any other river system on in the region. Increased Chinook runs in other rivers would help, but without improved Chinook populations in the Columbia system, the southern residents may not survive. Given this situation, the co-lead agencies must consider impacts on southern resident orcas in their analysis of the alternatives. Breaching the LSRDs is the single biggest action that can be taken right now to help this endangered cultural icon of the Pacific Northwest.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species."The EIS analysis found a minor effect to the Southern Resident killer whale (SRKW) would result from implementing Multiple Objective 3 (MO3), which includes breaching the four lower Snake River dams. This conclusion is based on the fact that Chinook salmon available to SRKW from the lower Snake River comprises only a small percentage of their overall diet. Changes to this portion of the whales food availability of the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but will not change their overall condition or population dynamics. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).
6485	7	johns944@wwu.edu	N/A	Discussion of salmon and orcas would be incomplete without considering their critical importance to the local tribes. The executive summary of the EIS describes tribal loss well in the following paragraph: Many of the tribes have not only lost access to traditional places, but have lost access to the one thing that all these places on the river had in common, which bound them together - the salmon. The loss of these foundational aspects of tribal culture has manifested itself across tribal communities in very tangible ways. The tribes cope with levels of poverty, ill health, and unemployment at significantly higher proportional rates than any other ethnic group in the country, which in turn leads to significantly higher mortality rates in comparison to non-native communities. (pg 12) Unfortunately, this apparent understanding hardly makes its way into the discussion of MO3.	Tribal input, concerns, treaty rights, and interests were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon and other natural resources to Tribes in a number of sections throughout the EIS. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Additional information regarding tribes is discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections, including the Vegetation, Wildlife, Wetlands, and Floodplain section within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by resource. Multiple Objective alternative 3 is noted as being preferred by many tribes.
6485	8	johns944@wwu.edu	N/A	Instead, the EIS executive summary states that MO3 could result in additional major adverse effects to archaeological sites due to potential exposure of 14,000 acres that are currently inundated (pg 28). Framing loss of underwater cultural preservation as adverse effects suggests that the tribes are somehow a relic of the past, which is not at all accurate.	The co-lead agencies disagree that the impact analysis to submerged cultural resources suggests that Tribes are not living communities. Section 3.16.3.6 in the Draft EIS provides an impact analysis of Multiple Objective alternative 3 to all of the cultural resources identified within the study area, including archaeological sites, traditional cultural properties (TCPs), and the historic built environment. In pages 3-1390 through 3-1391 of the Draft EIS, the co-lead agencies noted the exposure of TCPs would allow a resumption of traditional uses that have not been possible since the dams were constructed and this is viewed as a beneficial effect. The co-lead agencies are aware of continuing traditional uses and engage in coordination with the tribes on a frequent, if not daily basis.
6485	9	johns944@wwu.edu	N/A	By far the most important cultural resources are the ones that are currently being withheld by the hydroelectric system on the lower Snake: healthy salmon populations, and a free-flowing river. In fact, the destruction of Kettle Falls, Celilo Falls, and salmon runs is in violation of treaty rights, which supersede congressional law. In his independent assessment almost 20 years ago, Army Corps engineer Jim Waddell came to the conclusion that breaching the 4 lower Snake River dams made the most economic sense among the alternatives available. As an engineer who was not from the region, Waddell was relatively unbiased and reached this conclusion simply from weighing the evidence provided in the mostly complete EIS. However, due to entrenched support for dam retention, his conclusion was rewritten to favor the opposite approach.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes the measure to breach the four lower Snake River dams. However, the Preferred Alternative meets other objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and met only a subset of objectives. Thus, the co-lead agencies did not recommend the measure to breach the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as cooperating agencies, and over 30 of those invited agreed to participate. Staff from the cooperating agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation and configuration of the dams in the CRS. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The Draft EIS was subject to two internal agency reviews by Corps of Engineers reviewers not involved in the development of the document. Then the document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process. An independent panel of experts reviewed and provided feedback on the EIS and models used in the analysis. The final IEPR report will be publicly available.
6485	10	johns944@wwu.edu	N/A	In the last 20 years, the economic case for retaining the LSRDs has only gotten worse. With west coast states rapidly bringing on other renewables, the LSRDs make less sense than ever. An independent study by ECONorthwest, Lower Snake River Dams: Economic Tradeoffs of Removal, was completed in July 2019. They estimate a net benefit of 8.65 billion dollars for dam removal. I do acknowledge that there are costs to breaching the LSRDs. Though BPA is currently selling power at a much lower price than the cost of production, sometimes even paying California to take its excess power, there may be peak production situations where the extra power is needed. The increase in power shortages from once every 15 years to once every 7 years is something, though a shortage once every 7 years (with no replacement power source) is still quite infrequent, and again, non-hydroelectric renewables continue to increase in capacity in west coast states. Even assuming no new power sources are added to the region, roughly one extra power shortage every 15 years (over the no action alternative) seems like a small price to pay for giving salmon and southern resident orcas a real chance at recovery (see my comments on the NPA).	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. The EIS does not employ a cost-benefit framework for decision-making. This is consistent with NEPA guidance, which describes that the EIS should not be a cost-benefit analysis if there are important tradeoffs that are not quantified. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. A summary table in Section 7.4 has been added to provide a concise description of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a number of resources. The Vulcan Report employs a cost-benefit framework. Consequently, a focus solely on the monetized economic costs and benefits would exclude important tradeoffs associated with the alternatives communicated in the EIS, including effects on fish. Regarding passive-use values, Section 3.15.2.2 of the EIS describes the recent ECONorthwest study, highlighting the objective and approach to estimating willingness-to-pay for salmon restoration. The ECONorthwest analysis and the EIS employ different analytical frameworks and rely on different findings with respect to the outcomes of breaching the four lower Snake River dams. First, the ECONorthwest report applies a cost-benefit analysis framework, emphasizing monetization of all categories of impacts. Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on fish are not quantified as monetized economic values does not mean that they were not considered in the context of the analysis. Second, the findings of the ECONorthwest report that the benefits outweigh the costs of breaching the dams rely on the implicit assumption that breaching would result in restoration of salmon populations. The fish effects analysis in Section 3.5 of the EIS does not find that Multiple Objective alternative 3 would result in recovery of salmon or steelhead populations or in restoring the populations to historical levels. Thus, the values presented in the ECONorthwest report should not be considered as representative of the benefits of MO3. However, the results from the ECONorthwest study contribute to the overarching conclusion of Section 3.15.2.2 that describes that the literature consistently demonstrates that people hold passive use values for salmon.
6485	11	johns944@wwu.edu	N/A	Additionally, the analysis suggesting increased greenhouse gas emissions under MO3 does not consider the methane emitted in dam reservoirs; this data must be included. As stated previously, multiple independent analyses suggest that breaching would be a net economic benefit. Certainly, there would be regional changes.	Appendix G, Chapter 5 of the EIS details the assessment of reservoir methane emissions from the CRS dam and reservoir projects. The findings are summarized in Section 3.8. While the assessment acknowledges uncertainty related to the level of methane emissions across the CRS project reservoirs, it relies on the highest quality information to evaluate the potential impacts of the alternatives. Specifically, a 2017 Northwest Power and Conservation Council evaluation of available information found that data on these sites were insufficient to estimate the reservoir methane emissions specifically for the CRS, but described that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies would allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams. Additionally, as the commenter requests, the Corps' Walla Walla District conducted a study in 2016, which concluded that for the relatively clean reservoirs of the Federal CRS, which include the lower Snake River dams, conditions for low dissolved oxygen concentrations are not prevalent; thus methane gas is generally not an issue.
6485	12	johns944@wwu.edu	N/A	Though transportation by barge is currently federally subsidized to make it competitive with rail, increasing rail transportation would be expected to increase rail costs. However, with savings from areas like fish passage programs and federal barging subsidies, efforts could (and probably should) be made to provide financial support for local agricultural transportation.	Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Pacific Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS described in Section 3.10.3.5. The EIS finds that transportation of freight that is currently barged on the Lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. Financial support for local agriculture transportation increased costs is not within the action agencies' current authorities. Chapter 5 in the EIS describes the framework and assumptions for mitigation measures under each of the MOs. Fish program costs and navigation O&M costs are included in the cost analysis in Section 3.19.
6485	13	johns944@wwu.edu	N/A	Similarly, irrigation is a solvable problem. The EIS executive summary states that assuming 47,926 acres were no longer irrigated, the present value of the lost social welfare benefit under the MO3 alternative is $458 million (pg 28). However, we do not have to assume that the 47,926 acres would no longer be irrigated. Simply extending the water withdrawal pipes, which can be done at reasonable cost, would solve the issue.	This EIS discusses engineering solutions (pipeline extensions for example) in Section 3.12.3 Environmental Consequences - Specifically under Region C under the MO3 alternative (see page 3-1267, line 3244, in the Draft EIS) and in Appendix N. The report which this EIS draws upon, as discussed, concluded that modifying the existing pump system was cost prohibitive. In Region C under the MO3 alternative this analysis assumes that pumps are unable to deliver water to estimated at 48,000 acres.
6485	14	johns944@wwu.edu	N/A	The co-lead agencies have a responsibility to reduce bias against MO3 by including in their analysis shifting federal subsidies toward rail and mitigating irrigation impacts by extending water pipes.	This EIS discusses engineering solutions (pipeline extensions for example) in Section 3.12.3 Environmental Consequences - Specifically under Region C under the MO3 alternative (see page 3-1267, line 3244 in the Draft EIS) and in Appendix N. The report which this EIS draws upon, as discussed, concluded that modifying the existing pump system was cost prohibitive. In Region C under the MO3 alternative this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres. This is discussed in Section 3.12.3 under Region C and the MO3 alternative. NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide mitigation for the effects to private infrastructure such as irrigation pumps, wells, or private docks.
6488	1	darlene.chirman@gmail.com	N/A	The Executive Summary includes eight Resource Purposes, including: Provide for the conservation of fish and wildlife resources, including threatened, endangered, and sensitive species throughout the environment affected by System operations. The Columbia River System Operations Objectives include improving survival of juvenile, adult salmon. Given the mandate for federal project to recover endangered and threatened species, this conservation purpose for the 13 runs of threatened and endangered salmon and steelhead is inadequate. The DEIS states the 4% Smolt-to-Adult returns ratio (SAR) regional goal for recovery; this goal should be incorporated in the resource purpose/goal. Even the conservation goal is not assured under the Preferred alternative. The CSS model predicts less than 1% SAR. This survival rate, combined with climate change impacts, may result in extinction of some of these T&E populations. The Preferred Alternative fails to provide for the long term survival and recovery of threatened and endangered (T&E) runs of salmon and steelhead. This alternative is a modest modification of the current Flexible Spill operational experiment. The timing of the spills appear to benefit power generation over fish survival. As stated above, this alternative does not ensure the survival of the T&E fish populations. Despite the expenditures of $15-17 billion on fish management measures over decades, not one of these populations have recovered and removed from the Endangered Species List. In the Snake River, these fish populations have continued to decline.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call however is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the purpose and need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management and water supply, while minimizing adverse impacts to communities and the economy. It should be noted that the 4% Smolt-to-Adult return (SAR) target referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the Preferred Alternative analysis, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The co-lead agencies conclude the expected outcomes for salmon and steelhead associated with MO3 are appropriately acknowledged and framed appropriately with impacts to other authorized purposes. The comments suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
6488	2	darlene.chirman@gmail.com	N/A	The DEIS describes the Multiple Objective Alternative 3 (MO3) as developed the evaluate the effects of breaching the four lower Snake River dams: Lower Granite, Little Goose, Lower Monumental ad Ice Harbor. MO3 would also include spring juvenile fish passage spill with a target 120% Total Dissolves Gases (TDG) in the tailrace of the four lower Columbia River projects Executive Summary p24). Both models show the highest benefit to juvenile and adult salmon attributed to this alternative. The highest predicted potential smolt-to-adult returns resulted in the MO3 alternative. Given this analysis, it appears the MO3 Alternative would be selected as the Environmentally Superior Alternative and would be the Preferred Alternative recommended for implementation. The DEIS failed to make this recommendation. The rationales for not recommending MO3 as the Preferred Alternative are unsupported, in my view. The fish depend on the river for survival. There are other options for other services provided by the 4 dams.	The EIS set forth eight objectives which, in tandem with the Purpose and Need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. As described in Chapter 7 of the FEIS, the preferred alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective Alternative 3 (MO3), which includes breaching the four lower Snake River dams. The preferred alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply and greenhouse gas emissions, while minimizing adverse impacts to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Section 3.5 provides a summary of the fish analysis for the No Action Alternative and four of the multiple objective alternatives. Chapter 7 provides a summary of the fish analysis for the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets.
6488	3	darlene.chirman@gmail.com	N/A	The electricity generated in average water years is 1,100 aMW. This is a small portion of the overall power provided by the Columbia River System. The surplus power each year is more than provided by these 4 dams, and the income for sale of surplus power had decreased. This income is likely less than the cost of operating these dams, when the fish management costs are included (which are ineffective in maintaining T&E fish populations). Energy efficiencies in the region have decreased the power demand. It may be possible that no additional generating capacity would be needed to effect breaching the dams. The costs of other renewable energysolar and windhas come down dramatically, and planned projects in the region may meet any demand deficit. Greenhouse gas emissions need not rise, if any lost power generation is replaced by energy efficiency and other renewable energy generation.	While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. As described in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are among the most valuable projects in the FCRPS. These dams provide approximately 1,000 aMW of carbon-free energy on average and 2,000 MW of sustained peaking capacity at certain times of the year. See draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. The dams also provide important ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907 and Table 3-160. In addition, the EIS finds that, even assuming renewable resources replace the reduction in capacity under MO3, there would be an increase in regional greenhouse gas emissions because existing fossil-fuel plants would increase generation. See Section 3.8.3.5,at pages 3-1009-1010 in the Draft EIS. Under MO3, on average, the region has surplus generation leading to export sales during certain periods and water years. Nevertheless, to maintain regional reliability at the loss-of-load probability (LOLP) levels of the No Action Alternative, replacement resources would be needed. This is driven by the timing and magnitude of changes in hydropower generation analyzed in the EIS. As shown by the analysis of the LOLP, in some years and times of the year, particularly winter and later in the summer of drier years, without the four lower Snake River dams there would be insufficient power supply in the region leading to power emergencies and blackouts. Specifically, without replacing the power from the four lower Snake River dams, the LOLP of the region would more than double to 14 percent, which is equivalent to one year with one or more blackouts every seven years. See page 3-903 in the Draft EIS; see also Appendix H, Power and Transmission, at Table 2-1. The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options; however, to avoid speculation, the EIS analysis focuses on primary technologies identified by the Council in their 7th Power Plan (7th Power Plan page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821 in the Draft EIS; see also Appendix H, Power and Transmission, at Section 2.2. Regarding the potential for additional efficiency, the EIS included all cost-effective conservation identified by the Northwest Power and Conservation Council in the 7th Power Plan. See Appendix H, Power and Transmission, Section 2.2, H-2-3. Cost effective conservation in the region would be acquired pursuant to current law regardless of the status of the four lower Snake River dams. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four lower Snake River dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the FCRPS and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. Footnotes: 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRPS capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecast direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct fund operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric..
6488	4	darlene.chirman@gmail.com	N/A	Barge transport is another reason given in the DEIS to keep the 4 dams and their locks in operation. Other analyses show that barge transport has been declining dramatically over the past 20 years, a trajectory that is likely to continue even if the locks remain functional. Rail transport upgrades would aid the transition if the dams are breached. This appears to be inadequately analyzed in the DEIS.	Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Pacific Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS shows. It is true that barge movements on the Snake/Columbia river system have declined somewhat over the past 20 years, though the decline has stabilized over the past 10 years. The EIS discusses improvements in rail infrastructure that may be required in Section 3.10.3.5
6488	5	darlene.chirman@gmail.com	N/A	Benefits of MO3 dam breaching do not appear to be given sufficient weight in the calculus of rejecting this alternative as the Preferred Alternative. The DEIR acknowledges the major benefits for fish with this alternative. But it does not sufficiently value the increase in economic and cultural benefit of revival of the fishing communities and cultural heritage of salmonids to the Native American communities. Commercial and recreational fishing can regain their regional importance with the recovery of fish populations.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial although quantitative impacts from fish modeling results are limited. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The EIS recognizes the importance of salmon to Tribes in a number of Sections throughout the document. The Fisheries Section 3.15 as well as Section 3.17, in particular, include discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries Section 3.15.2.1, which includes sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries. The co-lead agencies also considered the information in the Tribal Perspectives that were submitted by several tribes during the drafting and evaluation of the EIS.
6488	6	darlene.chirman@gmail.com	N/A	The recovery of the riverine habitat on 140 river miles as the slackwater reservoirs drain, and the recovery of 15,000 acres currently inundated is mentioned but not given sufficient weight. Instead, the DEIS discusses the loss of reservoir recreation, and exposure of archeological sites. The recreational potential of the riverine habitat is not really addressed, and a mention is made of the cultural important of Native American sites that will no longer be inundated. While the river cruise ships will no longer be able to navigate this reach of the Snake River, local opportunities for river recreation while visitors stay in local accommodations has the potential to invigorate the local economies. These potential benefits are not sufficiently explored in the DEIS.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. The co-lead agencies are engaging in government-to-government consultation with the Tribes, and several Tribes are cooperating agencies on the CRSO EIS. Section 3.11.3.7 describes the potential economic impacts to Tribes. Discussion of Tribal community concerns and Tribal treaty rights were considered and are discussed in a number of sections throughout this EIS. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Tribal interests in fisheries are described in Section 3.15.4. Additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis in Section 3.11, including Tribal interests in Section 3.11.3.7. Many sections of Chapter 3 include a Tribal Interests sub-section at the end that attempts to summarize tribal issues by topic and Chapter 7 also includes additional information on the Preferred Alternative's impacts on these resources.
6488	7	darlene.chirman@gmail.com	N/A	Southern Resident Orcas, or Southern Resident Killer Whales (SRKW) are listed as federally endangered. Snake River Chinook are a major food source. The DEIS erroneously states The Snake River spring/summer Chinook salmon is a negligible portion of their overall diet. The DEIS is also flawed in that it utilizes outdated population data for SRKW. Fisheries scientists recommend the breaching of the 4 lower Snake River dams as the best chance of survival of the orcas 1. The DEIS cites inaccurately that the SRKW are found in the spring, summer and fall in the inland waters of Puget Sound and nearby, commonly known as the Salish Sea. However scientists have found that: this genetically distinct population of killer whales has spent more than half their time swimming back and forth throughout their known range as far south as Monterey, CA and as far north as Southeast Alaska. Their visits to the coastal waters off Westport, Washington and the mouth of the Columbia River coincide with high concentrations of spring Chinook salmon. 2 Thus the DEIS is flawed in not acknowledging the importance of the Snake River Chinook salmon in the survival and recovery of the Southern Resident Killer Whales.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
6488	8	darlene.chirman@gmail.com	N/A	Water Temperature. The DEIS does present data that the water temperature, especially in the slackwater reservoirs behind the dams, is at times in the summer above the safe temperature for salmonid survival. A press release from 55 fisheries and natural resource scientists to Northwest Policymakers3 describes the harm to survival of salmonids of temperatures over 68 degrees F, and presents data that this is now normal for extend periods in July, August, and September in the lower Snake River. This is expected to be exacerbated by the changing climate. The DEIS is deficient in that it neglects to include data from EPA modeling (2003) that the 4 lower Snake River dams collectively contribute up to 12 degrees of temperature elevation. The scientists state that breaching the 4 lower Snake River dams, MO3, would lower the temperature for the best habitat available for recovery of the salmonid populations. The recent 9th Circuit Court of Appeals requires the EPA to develop TMDLs for temperatures above 68o. The Final EIS needs to include recommendation of a plan that will address this critical issue.	The CRSO EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives effects on salmon and steelhead, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Water temperatures under MO3, which includes breaching the four Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the lower Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during high air temperature events. The models showed minor changes in the Columbia River under this alternative. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. The Comparative Survival Study (CSS) model indicates the Preferred Alternative would result in increased SARs of Snake River salmon and steelhead. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. With respect to the Preferred Alternative, the fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals. Regarding climate change, the climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at this time at the resolution required (river vs. region or global). Therefore, it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3). Regarding predicted water temperatures under MO3, as compared to the results documented by Schultz and Johnson (2017) and derived from past EPA analysis, there are a few key differences between EPA's RBM-10 model and the models used in the development of this EIS that should be made clear. First, the RBM-10 (TMDL) model predicts a daily average water temperature, while the CE-QUAL W2/RAS (EIS) model predicts a daily maximum value. The co-lead agencies chose the daily maximum water temperature metric since most water quality standards are based on this metric. Second, the RBM-10 model uses weather data from airport weather stations with the longest records, whereas the co-lead agencies used weather stations with the most spatial coverage and spatial representation (airport and AgriMet weather stations). Lastly, RBM-10 was utilized for a free-flowing scenario. The free-flowing scenario includes the absence of Grand Coulee, Chief Joseph, the five mid-Columbia PUD dams, the lower four Columbia River and the lower four Snake River dams. Dworshak Dam, however, was included in EPA's "free-flowing" scenario as a boundary condition and uses observed flows and temperatures. 2010 channel bathymetry is utilized throughout the system. The TMDL assessment focused on quantifying the thermal load of the dams by comparing existing conditions to a "free-flowing" scenario where Dworshak Dam is still in place. The co-lead agencies used HEC-RAS (1-dimensional model)for MO3 for the lower Snake River; CE-QUAL W2 (2-dimensional model) was used for the other mainstem CRS dams. MO3 includes breaching the four lower Snake River dams in which the earthen embankments of each dam are removed, leaving the concrete sections in place. All other CRS dams remain in place. Dworshak Dam uses modeled flows and temperature. 1934 (pre-dam) channel bathymetry is utilized throughout the lower Snake River; 2010 geomorphology used for elsewhere in the system. The CRSO EIS assessment focused on predicting water temperature and TDG conditions under MO3 . Given the differences between efforts, direct comparisons between the two assessments are not appropriate. The USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). The water temperature analysis specific to MO3 utilized the Dworshak CE-QUAL W2 (2-dimensional model) and the lower Snake River HEC-RAS (1-dimensional models) to predict water temperatures under a dam breach scenario, while incorporating operations at Dworshak Dam for downstream water temperature management. Specifically, 2016 No Action Alternative Dworshak operations were used in the MO3 analysis. The co-lead agencies agree with your concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used current high quality information and best resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. The study results indicate that the operations of the CRS do impact water temperature but the CRS has limited ability to reduce temperatures in the lower Snake and Columbia rivers outside of Dworshak operations. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool.
6495	1	president@visitlcvalley.com	N/A	Visit LC Valley strongly recommends expansion of the analysis of impacts behind MO3 because, while this is not the preferred option, there is tremendous attention being paid to it and the final EIS will set a foundation for future analysis.	The co-lead agencies agree that the analysis included to describe the effects of MO3 provides important information that may be referenced in the future. A sufficient level of detail has been provided on direct, indirect, and cumulative effects to form a scientific and analytic basis to compare alternatives as required the Council on Environmental Quality's Regulations for Implementing the Procedural Provision of the National Environmental Policy Act (40 C.F.R. Section 1502.14).This analysis will be used by the co-lead agency decisionmakers to make an informed decision in the Record of Decision and may be used by other decisionmakers in the future.
6495	2	president@visitlcvalley.com	N/A	SPECIFIC COMMENTS Impact on cruise boat industry: On page 3-1214, the CRSO DEIS correctly identifies that the cruise boat industry will no longer be able to operate under MO3. What it does not recognize that there is a yacht industry involving affluent people who rent large passenger vessels and crew to bring them through the locks and into the LC Valley. (They, like cruise boats, typically moor at the Port of Clarkston docks because they are too largedraft and size-wiseto fit into regular marina moorage slots.) For the cruise industry on the Columbia & Snake Rivers, the 2002 Lower Snake River Juvenile Salmon Mitigation Feasibility Report and EIS came up with an annual impact. I couldnt find that in the CRSO DEIS. In 2018, for the first time, passenger counts on the Columbia and Snake Rivers exceeded that on the Mississippi and that continued into 2019. In the LC Valley, since 2014, we	Cruise line visitation is characterized in Section 3.10, including a description of its economic contribution to the region. Section 3.10.3.5 describes the contribution of cruise ships as supporting approximately 230 jobs in the region, $6.2 million in labor income, and $17.8 million in annual output (sales). Section 3.10.3.5 describes the adverse effects to cruise line operations under MO3. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				have seen a 6.5% annual growth in visitation year after year. In 2019, the Valley was poised for much greater numbers, but Bonneville Dam had 5-weeks of closure to fix an infrastructure problem that curtailed visitation. America Cruises Lines, until COVID-19, has plans to add two additional boats on the Columbia and Snake, bringing the number of boats they had visiting the LC Valley up to 5 cycling through regularly. (NOTE: We saw a downturn in 2007 from a bad economy, but this industry recovered because the demand is there. This industry will recover from COVID-19, but we will not see that recovery if MO3 occurs and dams are removed.) The demand in the LC Valley has been exceeding the capacity, and 27 community partners combined resources to provide match on a study funded by EDA to help project growth and thus identify the future amenities that would be necessary to help meet the demand. AARP is giving us free press, as you can see from the attached February/March 2020 article attached. Impact on Hells Canyon National Recreation Area: Privately funded studies have pointed to growth of numbers of visits to Hells Canyon National Recreation Area, a boat-access only canyon which is North Americas deepest gorge. They incorrect point to recreation recovery because there is demonstrated interest in the form of increased numbers. What they dont realize is that 100% of the growth in number of visits to Hells Canyon is attributable to cruise boat passengers that take day cruises into the canyon by jet boat. Without the cruise industry partner, thousands of 70, 80, and 90-year-old mobility constraints citizens of the United States will not experience this end-of-life bucket list opportunity. Cruise lines solve huge access challenges for those individuals. Cruise lines also create critical mass such that a number of jet tour boat companies are in operation and market forces keep pricing down so that it is reasonable for all. If the cruise boat industry goes away, access to Hells Canyon National Recreation Area will be severely impacted, and one of the nations greatest treasures will be exceedingly hard to reach. Impact on sport fishing: It is difficult to comment on this issue because it is inconsistently handled throughout the report.	average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region.
6495	3	president@visitlcvalley.com	N/A	In Chapter 2, p. 36, it starts with Closure of the hatcheries funded by BPA will result in a loss of 19 million salmon, steelhead and resident rainbow trout being cultivated and released to the Snake River on an annual basis. The 2002 Lower Snake River Juvenile Salmon Mitigation Feasibility Report and EIS did not project increases in recreational fishing, likely because 80-90 percent of all juvenile Snake River fish passing CRS projects will be gone,	Hatchery contributions are considered in the analysis. As described in Section 3.5, the co-lead agencies anticipate that changes in hatchery funding may occur as needs and obligations shift. The co-lead agencies do not anticipate that hatchery operations would be shuttered. As noted in Section 3.5, the co-lead agencies also recognize that there would be transitional needs that would be addressed in the additional mitigation measures for MO3 discussed in Chapter 5. Additionally, the Bonneville F&W Program funding for offsite mitigation projects in the Snake River Basin, implemented by local, state, Tribal, and Federal entities, would be reviewed, and potentially adjusted. Any changes of this nature would be implemented over time as the effectiveness of dam breaching is observed and would be done in consultation with fish and wildlife managers, regulatory agencies, and the Northwest Power and Conservation Council. Consistent with this, offsite mitigation projects for the other CRS dams would be reviewed and could be adjusted as operations change over time. Proposed project modifications would be coordinated with project sponsors and regional stakeholders to determine appropriate funding levels." Although Bonneville's funding of the Lower Snake River Compensation Plan hatcheries would no longer be authorized, remaining fish hatcheries would continue to produce fish and other Federal or state entities may continue funding the hatcheries. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multiple objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
6495	4	president@visitlcvalley.com	N/A	Chapter 3, p. 548. COMPASS and CSS models to not account for this potential major reduction in juvenile fish production. So, both fish models project higher number of returns. Also projected, in the long term, under this CRSO DEIS is increased recreational fishing. VLCV would like to know how the loss of 80-90% of hatchery fish can still result in recreational fishing. Will fishers be able to take wild fish? The answer to this question will be key to VLCVs response, as promotion of recreational fishing is one of the important marketing activities in which we engage every year.	Regarding hatchery impacts associated with MO3, as described in Section 3.5, the co-lead agencies anticipate that changes in hatchery funding may occur as needs and obligations shift. The co-lead agencies do not anticipate that hatchery operations would be shuttered. As noted in Section 3.5, the co-lead agencies also recognize that there would be transitional needs that would be addressed in the additional mitigation measures for MO3 discussed in Chapter 5. Additionally, the Bonneville F&W Program funding for offsite mitigation projects in the Snake River Basin, implemented by local, state, Tribal, and Federal entities, would be reviewed, and potentially adjusted. Any changes of this nature would be implemented over time as the effectiveness of dam breaching is observed and would be done in consultation with fish and wildlife managers, regulatory agencies, and the Northwest Power and Conservation Council. Consistent with this, offsite mitigation projects for the other CRS dams would be reviewed and could be adjusted as operations change over time. Proposed project modifications would be coordinated with project sponsors and regional stakeholders to determine appropriate funding levels. Although Bonneville's funding of the Lower Snake River Comp Plan hatcheries would no longer be authorized under MO3, remaining fish hatcheries would continue to produce fish and other Federal or state entities may continue funding the hatcheries. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. For MO1, MO2, MO4, and the Preferred Alternative (PA), the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the PA and MO4 (i.e., models show either beneficial or adverse effects on anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term.
6495	5	president@visitlcvalley.com	N/A	Impact on golf courses: In the Lewis Clark Valley, given mild winters, golfing is year-round. One of the most frequently used packages VLCV puts together is hotel rooms and golfing. People from Spokane, Montana, Canada and other locations come here in the late fall, winter and early spring to golf. The 2002 Lower Snake River Juvenile Salmon Mitigation Feasibility Report and EIS recognizes that both the Lewiston Country Club Golf Course and the Clarkston Golf and Country Club rely on the Snake River as a source of water to keep their amenities. There is no discussion in the CRSO DEIS about how those golf course will continue to access surface water. It is important that they be allowed to do so.	As described in Section 3.12.3.4 Multiple Objective Alternative 3, Municipal and Industrial (M&I) water supply intakes in the Lewiston, ID area would likely be impacted by a dam breach scenario. Modifications to M&I systems would be required under MO3 increaing costs for supplying water to local communities and related industries like golf courses. NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. However, the co-lead agencies do not have the authority to provide mitigation for the effects to private infrastructure such as M&I systems.
6495	6	president@visitlcvalley.com	N/A	Impact on recreational trails including Clearwater Snake National Recreation Trails, the trail system at Hells Gate State Park, and other recreational amenities which are part of the 26 recreational facilities for which the Corps has ownership and management responsibilities: High school, college and middle competitive school track meets take place on the Clearwater Snake National Recreation Trail, bring participants and spectators from outside the area. Dozens of fun runs and marathons bring visitors to the LC Valley. Sometimes, people from a distance come to shop and enjoy the recreational amenities we have in the form of the trail, parks and other features on which the Corps has ownership and management responsibilities.	The co-lead agencies have included a discussion of community concerns about the potential impacts of MO3 in the navigation Section in Section 3.10.3.5, in subsection under Regional Economic Effects called "City/Local Effects Associated with Changes in Commercial Navigation, Cruise Lines, and Ferry Operations" as well as under the Other Social Effects subsections. These sections describe potential regional economic as well as social and community impacts associated with dam breach. The EIS recognizes the short-term adverse effects to recreation visitation and values, including cruise and tour boats, and the associated impacts to the regional economy under MO3, which includes the dam breach measure, which are described in Sections 3.10.3.5 and 3.11.3.5.
6495	7	president@visitlcvalley.com	N/A	Chapter 3, page 1213, discusses the uncertainty of who would own and manage the lands, recreational facilities and more in the lower Snake River under MO3. VLCV supports Corps continued ownership and maintenance of recreational amenities along the Snake and Clearwater rivers, in part because the Corps can access surface water to irrigate these amenities, which is not an option for most municipalities.	Since the lower Snake River projects would be deauthorized, the co-lead agencies would no longer operate the project lands for recreation. After project lands have been transferred to other agencies and/or entities, recreational sites and associated facilities could be modified as determined by others. Chapter 5 in the EIS describes the proposed mitigation measures under each of the MOs. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3 dam breaching. Mitigation by the co-lead agencies is not anticipated under MO3 to maintain access to the river. However, if breaching were to be selected as the Preferred Alternative, further evaluation, studies, and NEPA would be required along with congressional authorization and appropriations to implement the alternative. At this time, it is assumed that the co-lead agencies would no longer operate the project lands after the projects are deauthorized.
6495	8	president@visitlcvalley.com	N/A	SUMMARY As shown above, VLCV believes the negative impacts to the Lewis-Clark Valley in the CRSO DEIS are understated and requests modification by BPA, BLM and the Corps to better quantify and mitigate impacts.	If breaching were to be selected as the Preferred Alternative, further evaluation, studies, and NEPA would be required along with congressional authorization and appropriations to implement the alternative. At this time, it is assumed that the co-lead agencies would no longer operate the project lands after the projects are deauthorized.
6506	1	Columbia River Keepers	Columbia River Keepers	Riverkeepers comments1 on the DEIS will focus largely on water temperature, dams and dam removal, climate change, and the implications for fish survival and recovery.2 High summer and fall water temperatures already limit the survival of some salmon runs and significantly threaten the future of many Columbia and Snake river salmon fisheries. In 2015, for instance, more than 250,000 adult sockeye died in the Columbia and Snake rivers because warm water prevented them from successfully migrating upstream, trapping them in lethal conditions. In response to temperature-driven fish kills, the Environmental Protection Agency (EPA) noted that [t]he need to lower water temperatures becomes more critical as the Pacific Northwest Region continues to address and mitigate climate change.3 The Fish Passage Center similarly concluded that under a climate change scenario, the long-recognized and largely unaddressed problem of high water temperatures in the [Columbia and Snake rivers] becomes an ever-increasing threat to the survival of salmon . . . .4 Unfortunately, the DEIS overall narrative about water temperature, dams and dam removal, and climate change is incomplete,	The co-lead agencies have used the best information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. As stated in the comment, predicted water temperatures under MO3, which includes breaching the four Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action Alternative conditions in the Snake River. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times, especially during hot weather events. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. Therefore it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3 and Section 7.8.4).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				occasionally misleading, andperhaps worst of alllargely divorced from the context of salmon migration, survival, and recovery. Despite its many defects, the DEIS does admit that dam removal would significantly improve the water temperature regime and migration conditions for salmon and steelhead in the Lower Snake River. For instance, the DEIS states that dam breaching would have moderate to major beneficial effects on water quality in [the Lower Snake River] through the restoration of natural, river, and water quality processes; a substantial cooling effect in the fall; greater nighttime cooling[;] and respite from warm water temperature conditions in the summer.5 As explained below, this and similar admissions are greatly overshadowed by the DEISs general narrative implying that Lower Snake dam removal would not significantly influence water temperatures.	
6506	2	Columbia River Keepers	Columbia River Keepers	I. Breaching the Four Lower Snake River Dams Should be Part of the Final Preferred Alternative in the DEIS. Riverkeeper joins the Nez Perce Tribe, Shoshone Bannock Tribe, the Upper Snake River Tribes (USRT), Oregons Governor Kate Brown, and hundreds of thousands of people and organizations from across the Pacific Northwest and the United States in calling for the restoration of the Lower Snake River. Snake River sockeye and steelhead are perilously close to extinction now, and it is widely acknowledged that Snake River Chinook are unlikely to survive coming decades without significant changes to the status quo.6 With these risks in mind, the small, incremental improvements7 touted by the action agencies are legally,8 ecologically, and morally untenable. After twenty years of failed incrementalism, the action agencies should do what they have long resisted: recommend the removal of the Lower Snake River dams. Even the DEIS shows that Lower Snake River dam removal is the best way to avoid extinction and recover Snake River salmon and steelheadalthough a combination of the DEIS alternatives 3 (dam removal) and 4 (increased spill) would be even more effective. The Fish Passage Centers modeling of Snake River steelhead and spring/summer Chinook survival shows that the action agencies preferred alternative would not meet the criteria for recoverybut dam removal will.9 NMFS own survival model also shows that dam removal would have the most significant benefit to Snake River salmon and steelhead.10, 11 Setting aside disagreements 6 See New York Times, How Long Before These Salmon Are Gone? Maybe 20 Years (September 16, 2019) (quoting U.S. Forest Service fisheries research scientist Russ Thurow as saying that wild Snake River Chinook may go extinct in four generations or 20 years); see also The Lewiston Tribune, Simpson offers critical remarks on river study (March 12, 2020) (quoting Idaho Congressman Mike Simpson as saying in the next 15 years, if something isnt done, [Snake River salmon] will be extinct. There is no doubt about that, they will be extinct.). 7 DEIS, p. 7-89. 8 Riverkeeper reiterates, and incorporates by reference, Earthjustices comment that mere improvement or benefit to salmon and steelhead is a legally insufficient purpose and need statement under the National Environmental Policy Act (NEPA). 9 See Fish Passage Center, Comparative Survival Study of PIT-tagged Spring/Summer/Fall Chinook, Summer Steelhead, and Sockeye: 2019 Annual Report, Chapter 2 (December 2019). 10 DEIS, Executive Summary, p. 25. 11 Importantly, neither survival model appears to account for the benefits of decreased exposure to warm water and increased adult survival that would likely result from Lower Snake River dam removal. Pers. Comm. with Margaret Filardo, ret. Fish Passage Center staff (March 26, 2019). Accordingly, these models are likely underestimating the improvements to SARs that could result from Lower Snake River dam removal. Columbia Riverkeepers FCRPS DEIS Comments - 4 between (and about) the models, the difference in survival between stocks that traverse the Lower Snake, and the mid-Columbia stocks that do not, strongly suggests that the Lower Snake River dams are preventing the recovery of Snake River salmon and steelhead. As the Columbia River Inter-tribal Fish Commission (CRITFC) pointed out, salmon and steelhead in the John Day, Deschutes, Yakima, and Umatilla rivers consistently survive the hydrosystem well enough to meet recovery goals. Snake River stocks consistently fail to meet these same goals. From a fishs perspective, the difference is four dams and 140 miles of warm, slack water in the Lower Snake. The DEIS does not seriously dispute this conclusion. The action agencies fundamental mistake is believingdespite nearly 100 years of evidence to the contrarythat engineered solutions can replace or improve upon the productivity of the Columbia basins natural conditions. This preference for engineered solutions over ecological systems is central to the culture and identity of the Army Corps and BOR. But this paradigm for managing our river has failed; it defies common sense, over a century of EuroAmerican experience, the Traditional Ecological Knowledge of cultures that sustainably managed these fisheries since time immemorial,12 and scientific findings prepared for the Northwest Power and Conservation Council.13 As Idaho Congressman Mike Simpson succinctly stated, Salmon need one thingthey need a river.14 The preferred alternative in the final EIS should depart from action agencies failed paradigm and recommend the measure most likely to restore healthy runs of salmon to the Snake River basin.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the draft EIS, the co-lead agencies did not recommend MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws, including those pertaining to natural and cultural resources. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The co-lead agencies used high quality information in the EIS analysis. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Council recovery targets for the region) increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets. Moreover, the co-lead agencies disagree the Preferred Alternative is a continuation of the status quo. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The Preferred Alternative also includes other operational, structural and mitigation measures to improve conditions for ESA-listed salmon and steelhead. Additionally, the EIS evaluates the impacts to water temperature from MO3 and acknowledges long-term major beneficial effects on water quality, including major reductions in TDG and nighttime and fall water temperatures. The EIS does recognize, however, temperatures would still exceed water temperature standards in the summer during hot weather events. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The Preferred Alternative also includes other operational, structural and mitigation measures to improve conditions for ESA-listed salmon and steelhead.
6506	3	Columbia River Keepers	Columbia River Keepers	II. The Alternatives Analysis Violates NEPA. NEPA requires that every EIS analyze a reasonable range of alternatives and take a hard look at the environmental consequences of each alternative so that decision-makers and the public can readily understand the implications of the choices before the agency. For the following reasons, the DEIS does not meet these requirements. A. Maintaining the status quo means extinction for Snake River sockeye and steelhead. The DEIS fails to take a hard look at the consequences of the No Action Alternative (NAA) by failing to explain that maintaining the current status quo will likely lead to the extinction of Snake River sockeye and steelhead in the near term. The DEIS describes the measures included in the NAA and models their implications for fish survival. These models indicate that the smolt-to-adult return rates expected under the NAA will not lead to recovery.15 12 See, e.g., Shoshone-Bannock Tribes, CRSO Tribal Perspectives Document, p. 10 (DEIS, Appendix P). 13 See generally, The Independent Scientific Group, Return to the River: Restoration of Salmonid Fishes in the Columbia River Ecosystem, Chapter 2 (September 10, 1996). 14 The Lewiston Tribune, Simpson offers critical remarks on river study (March 12, 2020). 15 See DEIS, pp. 3-387, 3-384 (using Snake River spring/summer Chinook survival rates as a proxy for Snake River sockeye survival rates), 7-100, 7-102. Columbia Riverkeepers FCRPS DEIS Comments - 5 What the DEIS does not explain is that Snake River sockeye and steelhead stocks are in a state of collapse and that failure to substantially recover in the near term will very likely lead to extinction. This critical omission obscures the consequences of the NAA, especially when accounting for intensify climate change, and does not constitute the hard look that NEPA requires.	The Co-Lead Agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws, such as the Endangered Species Act (ESA), to evaluate impacts to listed species such as sockeye and steelhead. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of the National Marine Fisheries Service and the US Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally-authorized purposes while minimizing impacts to affected ESA species and their habitats. Both human-caused and natural factors that are outside the responsibility and control of the co-lead federal agencies, also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the Columbia River System requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a substantial contribution towards recovery.
6506	4	Columbia River Keepers	Columbia River Keepers	B. The DEIS multiple objectives approach to fails to present a reasonable range of alternatives. The alternatives presented in the DEIS violate NEPA because they are not distinct enough to present decision-makers and the public with realistic and intelligible choices. The point of NEPAs alternatives requirement is to describe the range of options before the agency and the corresponding range of environmental consequences that could flow from the decision. Unfortunately, the action agencies use of so-called multiple objective alternatives makes this impossible. The DEIS should have presented a suite of true alternatives that reflect a reasonable range of potential FCRPS operations and the consequences. Instead, the DEIS proposed five multiple objective alternatives that are, with the exception of Lower Snake River dam removal, so similar as to prevent meaningful comparison. Further, the multiple objective alternatives contain competing or contradictory measures that often obscure the potential environmental benefit of measures disfavored by the action agencies, such as Lower Snake River dam removal or increased spill. To address this problem, the final EIS should abandon the multiple objectives approach and analyze alternatives focused on maximizing different benefits of hydrosystem operations, including fish survival. This approach will allow decision-makers and the public to understand the true range of outcomes that could be achieved.	The Co-Lead Agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. The approach allows the co-lead agencies to understand the trade-offs of different measures to benefit the system operations. The co-lead agencies disagree the analysis in for the multiple objective alternatives is obscured. The effects analysis is clearly presented in Chapters 3, 4, 6, and 7 and relevant appendices.
6506	5	Columbia River Keepers	Columbia River Keepers	C. The EIS should consider profound changes to the status quo. The DEIS should have analyzed removing the lower four Columbia River dams. The Yakama and Lummi Nations, Columbia Riverkeeper, and many others have called for the removal of these dams to restore Columbia River fisheries and Southern Resident orcas, honor treaty commitments, and improve ecosystem function to mitigate for the negative impacts of climate change. Additionally, analyzing lower Columbia dam removal would give DEIS readers a better sense of the benefits of a more natural river system, which the action agencies illegal and myopic focus on dam operations obscures. Lower Columbia dam removal (like Snake River dam removal) is not beyond the action agencies existing authority and, even if it were, that would not preclude its consideration in a NEPA analysis. These dams were not built to last forever; one is approaching 90 years old. The four lower Columbia dams may be part of the action agencies cultures and identities but they have significantly disrupted the culture, identity, and economy of many others throughout the Northwest. In the mid-term, their electricity is not irreplaceable, or even particularly significant, given the energy revolution necessary to achieve deep decarbonization goals in the Pacific Northwest. This EIS process is a rare opportunity to Columbia Riverkeepers FCRPS DEIS Comments - 6 weigh real changes to the status quo. As we enter the 21st century, the action agencies should reconsider the value and trade-offs of their 19th century technology.	The co-lead Agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. As described in Chapter 2, many alternatives were considered and then eliminated from further consideration for the reasons described therein. An alternative breaching the four lower Columbia River dams was not analyzed because it is not a reasonable alternative due to its unreasonable impacts to public health and safety (e.g. power and transmission reliability events and flood risk management issues) and would not meet the Purpose and Need Statement or many objectives. Recovery of ESA species is the purview of the National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their habitats. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					As required by NEPA, the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapter 3, summarized by resource and alternative in Table 3-1, and once again presented for comparison in Tables 7-1 and 7-55. The EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. As for mitigating for climate change, while the Draft EIS contains analysis in regards to climate change (Chapter 4), the co-lead agencies are not charged with mitigating the effects of climate change within this Draft EIS – that is outside the co-lead agencies' authorities and outside the scope of this EIS.
6506	6	Columbia River Keepers	Columbia River Keepers	The DEIS should also have analyzed of the impacts of summertime reservoir draw-downs on temperature and salmonid survival in the Lower Snake River as well as at McNary and John Day dams. As explained below, these reservoirs significantly increase water temperatures and impair fish migration and survival. Drawing down these reservoirs to the spillway crest during certain times has the potential to decrease water temperature due to smaller reservoir surface area and decreased water residence times. While this level of draw-dawn could require modification to fishways and other dam structures, the cost of such modifications should be compared to other measures under contemplation to improve fish survivalincluding dam removal and the concurrent permanent loss of electric generating capacity. Given the ongoing search for regional solutions to the fish passage problems caused by these dams and reservoirs, the action agencies should have modeled the water temperature impacts of reservoir draw-downs and discussed the implications for salmon and steelhead migration survival and recovery.	The purpose of this EIS is to assess impacts from the continued operation and maintenance of the existing projects of the Columbia River System and not to assess pre-project conditions The alternatives analysis did contemplate changes to pool elevations in some projects, for example at John Day, and these results were integrated into the water quality results summarized in Section 3.4 and Appendix D.
6506	7	Columbia River Keepers	Columbia River Keepers	D. The DEIS discussion of dam removal in MOA3 is arbitrary and capricious. First and most importantly, Riverkeeper is appalledbut not surprisedby BPAs continued attempts to leverage fish mitigation in the Snake River basin against Lower Snake River dam removal. The DEIS implies that Snake River dam removal would necessarily result in the immediate termination of the LSRCP, soon followed by significant reductions in fisheries mitigation work throughout the Snake basin.16 Given ongoing legislative efforts to resolve the deep-seated problems with the FCRPS, and the action agencies own assertions that dam removal would require additional legislation, BPAs attempt to couch its threat as an unavoidable legal consequence of lower Snake dam removal does not hold water. After decimating the fisheries resources of the Snake River basin, BPA blithely proposes to bulldoze holes in the four Lower Snake dams and walk away from the mess it createdleaving states, tribes, and stakeholders to rebuild what the action agencies destroyed. Moreover, the DEIS overtly transactional tone is a wholly inappropriate when addressing the tribal and state sovereigns whose fisheries resources have been degraded or eliminated and who effectuate BPAs mitigation obligations on the ground. The Northwest Power Act and the Endangered Species Act obligate BPA to mitigate some of the damage caused by the FCRPS. The discretion afforded BPA in deciding how to carry out this mitigation should never be used as a carrot or wedge to influence regional policy choices.	Breaching the embankments accomplishes the purpose of opening the river for unencumbered fish migration. Full removal of dam components is a larger and more costly construction project, including additional siting and disposal of materials. It would result in a greater cost both in adverse environmental effects and Federal appropriations without any significant benefit to fish. The Draft EIS acknowledges that with the breaching of the four lower Snake River dams in MO3, there would no longer be an obligation to fund the Lower Snake River Compensation Plan, which accounts for much of the hatchery production in the basin and other mitigation activities could be adjusted. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. The fish models are based upon data collected from past fish runs and there is no data available to inform a quantitative analysis for wild fish in the absence of hatchery fish. Over time, increased returns of wild fish would be expected as wild fish replace hatchery fish, and the Snake River resident fishery would improve as the reservoir habitats transition to riverine. The long term overall effect of MO3 would be beneficial for Snake River salmon and steelhead as well as resident fish, so no mitigation for this effect was identified. Additional hatchery production would be in place for limited years to offset the short term dam breaching and construction effects. Mitigation measures were proposed for both anadromous and resident fish for a transitional period for the breaching of the four lower Snake River dam embankments, as described in Sections 5.4.3.2 and 5.4.3.3. Proposed mitigation includes two years of hatchery production along with trap and haul operations for the anadromous fish during this period. These mitigation measures would reduce adverse effects to resident and anadromous fish in Region C. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic.
6506	8	Columbia River Keepers	Columbia River Keepers	Similarly, it is duplicitous and unscientific for the action agencies to repeatedly reference pre-dam water temperature observation in the Lower Snake River when describing the consequences of Lower Snake River dam removal and Alternative 3. Even if those measurements were reliable or representative, once-daily surface temperature samples are not 16 DEIS, pp. 1-45, 3-250, 3-548. Columbia Riverkeepers FCRPS DEIS Comments - 7 particularly helpful for understanding how the Lower Snake Rivers water temperature regime influenced fish passage and survival17 (a mistake perpetuated by the DEIS singular focus on current daily maximum water temperatures). Furthermore, the DEIS steadfastly ignores other pre-dam conditionsespecially conditions that show the dams deleterious impact or undermine the action agencies long-held policy preferences. For instance, the DEIS does not present predam water temperature or flow data for the main-stem Columbia or the estuary. And the DEIS fails to mention that Snake River coho were historically abundant, went extinct after the construction of the Lower Snake River dams, and were only recently re-introduced by the Nez Perce Tribe. Presenting questionably relevant data on pre-dam conditions only where it appears to support a long-established policy preference is arbitrary and capricious and only serves to highlight the action agencies bias.	Historical water temperature measurements were collected from 1955 to 1958, which are reported in the EIS. This information helps to build historical context and provide an idea of what water temperatures would have looked like prior to the construction of the lower Snake River and Hells Canyon Complex dams, as breaching the lower Snake River dams was analyzed extensively in this EIS and pre-dam temperatures are relevant to the analysis. The lower Snake River dams include Lower Granite Dam (constructed in 1975), Little Goose Dam (constructed in 1970), Lower Monumental Dam (constructed in 1969) and Ice Harbor Dam (constructed in 1961), while the Hills Canyon reach dams include Brownlee (constructed in 1959), Oxbow Dam (constructed in 1961) and Hells Canyon Dam constructed in (1967). No Corps dams existed on the Snake River prior to 1961. The fish benefits of breaching the Snake River dams is discussed in the analyses of Snake River salmon and steelhead in the EIS. Faster travel times, among other parameters such as temperature differences, under a breach scenario was incorporated into both models that were used to estimate juvenile survival and, as reported in the EIS, both indicated higher juvenile survival than the No Action Alternative. For Snake River spring/summer Chinook Salmon, decreased travel time of 4.5 days and 5.5 days, respectively, were indicated by CSS and NMFS COMPASS models, compared to the No Action Alternative. The water temperature model used to analyze all EIS alternatives underwent significant review by experts outside of the co-lead agencies, including scientists from the USEPA, USGS, and Portland State University. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the EIS (see EPA review comment letter # 16-0059).
6506	9	Columbia River Keepers	Columbia River Keepers	Finally, the DEIS discussion of Alternative 3 should explain that Lower Snake River dam removal could enhance the benefit of cold-water releases from Dworshak Reservoir.18 The DEIS concedes that, with the Lower Snake dams in place, the cooling effect of Dworshaks water diminishes significantly downstream of Lower Granite dam. However, the DEIS does a poor job of explaining that, without the four dams, the cold water from Dworshak could meaningfully and quickly decrease water temperatures throughout entire the Lower Snake River. Both HEC-RAS and RBM-10 models predict that daily average temperatures in a freeflowing Lower Snake River at Ice Harbor Dam would have significantly declined following a major increase in Dworshak water releases in late June 2015and significantly increased just after Dworshak releases were curtailed at the beginning of August 2015. The two figures below describe the daily average temperatures in the Lower Snake at Ice Harbor in 2015, both as observed temperatures and temperatures predicted without the dams. Both figures predict that the 17 See Exhibit 4. Margaret Filardo et al., Letter to Gene Spangrude re: historic Snake River water temperature observations (November 13, 2019). 18 See Exhibit 5, EPA, Draft Assessment of Impacts to Columbia and Snake River Temperatures using the RBM10 Model, pp. 3940 (December 19, 2018) (predicting lower monthly average temperatures in July, August, and September in the Lower Snake River if the dams were breached and Dworshak releases continued.) Columbia Riverkeepers FCRPS DEIS Comments - 8 average temperature of the free-flowing Snake River at Ice Harbor would have declined sharply in early July and risen sharply again in early August of 2015. What could explain these significant changes in temperature? The next figure shows water releases from Dworshak Dam over the same period. The hydrograph above shows that cold water releases from Dworshak more than doubled in late June of 2015just before the Corps and Riverkeepers modeling both predicted a significant decline in the free-flowing rivers temperature at Ice Harbor. Similarly, the hydrograph shows that Dworshak water releases decreased sharply at the beginning of August 2015and the models predicted significant temperature increases at Ice Harbor shortly thereafter. In contrast, the temperatures observed in the dammed river at Ice Harbor in 2015 showed no noticeable reaction to Dworshak operations. This anecdotal evidence supports the commons-sense conclusion that breaching the Lower Snake River dams would allow Dworshak releases to significantly and quickly influence water temperaturesand improve fish migrationthroughout the entire Lower Snake River. Instead of ignoring and obscuring19 this important point, the DEIS should have investigated how to optimize Dworshak releases to regulate water temperature and improve fish survival in a free-flowing Lower Snake. For instance, Alternative 1 proposes releasing more Dworshak water in June/July, less in August, and more again in September/October. This schedule would release cold water during the peak of the sockeye and spring/summer Chinook migrations in June/July and again during the peak of fall Chinook and 19 As explained in Section IV and V, below, focusing exclusively on daily maximum temperatures obscures important information about how dam removal would affect water temperatures and fish survival. Columbia Riverkeepers FCRPS DEIS Comments - 9 steelhead migrations in September/October. Because Alternative 1 does not include Lower Snake dam removal, temperature modeling of this alternative showed (unsurprisingly) that an early summer/early fall Dworshak release schedule would have little to no impact on water temperatures or fish survival in the	The water temperature analysis specific to MO3 (which contains the dam breaching measure) utilized the Dworshak CE-QUAL W2 (2-dimensional model) and the lower Snake River HEC-RAS (1-demesional models) to predict water temperatures under a dam breach scenario, while incorporating operations at Dworshak Dam for downstream water temperature management. Specifically, from the 2016 No Action Alternative were used in the MO3 analysis. Results were provided to the fish team for incorporation into COMPASS and CSS modeling and other analysis to evaluate the impacts to anadromous fish. Future dam breaching analysis may provide an opportunity to investigate Dworshak Dam operations further, but this would need to occur outside of the EIS process and under a more appropriate study framework.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Lower Snake River. A much more interesting and revealing question would be: how would the Alternative 1 (or other) Dworshak release schedule influence temperature and fish migration in a free-flowing Snake River? The DEIS should have investigated how the combination of Snake River dam removal and different Dworshak dam release patterns could provide the most benefit for fish survival.	
6506	10	Columbia River Keepers	Columbia River Keepers	The DEIS conceals the hydrosystems significant impact on water temperature in the lower Columbia River. Recent modeling by EPA (below) shows that the summer water temperatures at John Day dam are significantly warmer because of the John Day pool and upstream reservoirs.20 EPA modeling also shows that John Day and McNary dams together raise the temperature of the Columbia an average of 0.5 and 0.6 degrees C in August and September, respectively.21 While these results show significant temperature increases due to the dams, Riverkeeper notes that EPAs modeling only examines river temperature with and without dams under current flow conditions. Modeling temperature under a natural (i.e. pre-FCRPS and Columbia River Treaty) hydrograph where the freshet was more pronounced and lasted longer into the summer would 20 Exhibit 6, EPA, Columbia River Temperature TMDL: State and Tribal Meetings PowerPoint Presentation, Slide 33 (January 2020). 21 See Exhibit 5, pp. 2829. 10 12 14 16 18 20 22 24 90 140 190 240 290 deg C Julian Day John Day Tailrace RBM10 2007-2016 Dams No Dams AUG July SEPT Columbia Riverkeepers FCRPS DEIS Comments - 10 show the true extent of the FCRPS temperature impacts. The action agencies refusal to discuss pre-dam conditions or consider alternatives that meaningfully depart from the status quo results in a DEIS that conceals the hydrosystems significant impact on water temperature in the lower Columbia River and its implications for salmon survival.	As stated in the Purpose and Need Statement in Section 1.2, the ongoing action that requires evaluation under NEPA is the long-term coordinated operation and management of the CRS projects for the multiple purposes. As mentioned in the Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations, in the case where there is an ongoing management program or plan, the No Action Alternative would be "no change" from current management program or plan. The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 C.F.R. 1502.14) and provides a benchmark for comparing environmental effects of the other alternatives. The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change. Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). Please note that model calibration reports were developed for all water quality models and are available by request.
6506	11	Columbia River Keepers	Columbia River Keepers	Furthermore, the DEISs reliance on EPAs unpublished temperature refuges study and temperature TMDL is misplaced, cynical, and incorrectly implies that the action agencies can foist the main-stem Columbia water temperature problems onto EPA. First, temperature refuges will not address many of the temperature-related fish passage problems in the lower Columbia because temperature refuges do not: address the cause of, or solutions to, high water temperatures; address temperature barriers at fishways; benefit adult sockeye or spring/summer Chinook; benefit out-migrating juvenile salmonids experiencing high water temperatures, or; exist in the mainstem Columbia or Snake rivers upstream of John Day dam.22 Second, the action agencies and federal government should not pretend to rely on a currently non-existent temperature TMDL that they have actively, and successfully, resisted for the last 20 years. A temperature TMDL could provide a meaningful plan to reduce water temperature in the Columbia and the Lower Snake. Unfortunately, the action agencies have worked to prevent and undermine the development of such a plan for the past two decades. When EPA put forth a draft temperature TMDL in 2002, the action agencies convinced the Bush administration to shelve that plan. When it appeared the TMDL might go forward anyway, the action agencies pressured EPA to ignore the impacts of the dams on temperature and pressured Oregon and Washington to exempt the dams from the Clean Water Act using a process called a Use Attainability Analysis. After the Ninth Circuit recently ordered EPA to produce the TMDL, the federal government took the extraordinary measure of asking that court to re-consider its opinion en bancbut not a single Ninth Circuit judge thought the case worthy of rehearing. It is cynical in the extreme for the federal government to imply that a currently non-existent temperature TMDL will help address water temperature problems. Regardless of the status of EPAs TMDL and thermal refuges work, the DEIS should realistically and clearly analyze whether the hydrosystem is causing or contributing to compliance with the water quality standards.23	The co-lead agencies have used the best information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. The study results indicate that the alternatives considered in the EIS have limited ability to reduce temperatures in the lower Snake and Columbia rivers compared to the No Action Alternative. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool. Temperature in the Snake River upstream of the confluence with the Clearwater River often exceeds state water quality standards. Drier and warmer years such as 2015, as summarized in NOAAs 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) point out that tributary temperatures in the Okanogan and Salmon rivers were above 25C. The EPA is the lead agency on developing the temperature TMDL, and in doing so will evaluate the impact of all anthropogenic and natural sources of heat in the Columbia and Snake rivers. In contrast, the Draft EIS evaluated the impact of several actions the co-lead agencies could take and their impact on river temperatures as they relate to current and historic river temperatures. In addition to investigating the operational impacts on water temperature, the co-lead agencies have taken other actions to address water temperature impacts on fish passage. Cooling water pumps have been installed at Lower Granite and Little Goose adult passage ladders to reduce temperature differentials between ladder and river and to reduce thermal stress during upstream passage. In addition, the co-lead agencies are actively working on implementing the recommendations identified in NMFS' 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) to improve management decision making and reduce, to the extent practicable, the negative impacts of high summer temperatures on migrating salmon, including adult sockeye salmon.
6506	12	Columbia River Keepers	Columbia River Keepers	IV. The DEIS Overall Narrative About Temperature in a Free-flowing Snake River is Misleading and Incorrect. Overall, the DEIS gives the incorrect impression that dam removal would cause the Lower Snake River to warm earlier in the spring, have no effect on temperature in the summer, and cool earlier in the falland that the spring and fall effects are equivalent in magnitude and 22 See, generally, Exhibit 7, Northwest Environmental Advocates, Comments on Draft Columbia River Cold Water Refuges Plan (November 19, 2019). 23 See Exhibit 1, pp. 23. Columbia Riverkeepers FCRPS DEIS Comments - 11 counterbalance each other in terms of benefits to fish. For instance, the DEIS says that dam breaching: . . . is expected to result in warmer water temperature in the spring, similar water temperatures in the summer, and cooler water temperatures in the fall . . .24 This oft-repeated narrative leaves readers with the impression that Lower Snake River dam removal would not substantially improve water temperatures or fish migration conditions. This is untrue. A. The free-flowing Lower Snake would not be meaningfully warmer in the spring. Contrary to the DEIS general narrative, the DEIS data show that the free-flowing Lower Snake would not be meaningfully warmer in the spring (e.g. March, April, and May) than the dammed river. When ranges of uncertainty were incorporated into the models results, springtime temperatures in the free-flowing river almost never exceed the dammed river.25 In March and April, the DEIS modeling does predicts that the monthly average temperature at Ice Harbor could be one or two degrees F warmer in the free-flowing river.26 But in March and April, the free-flowing Lower Snake River would almost never be warmer that 56 degrees F27 and therefore would remain well below the temperature thresholds known to impair salmon and steelhead migration.28 The small temperature difference resulting from Lower Snake dam removal in March and April is, therefore, not relevant to the fisheries resource. And in May, the DEIS actually predicts that snowmelt runoff would cause the free-flowing Lower Snake to be colder than the dammed river.29 Accordingly, the federal agencies long-time narrative that the free-flowing Lower Snake would be warmer in the spring is not scientifically viable; irrelevant and misleading (with respect to March and April); and untrue (with respect to May).	The EIS documents that the spring warming is less than extreme than the fall cooling when comparing MO3 (dam breach) to the No Action Alternative. Regarding water temperatures in the lower Snake River, it is well known that reservoirs create a lag in the thermal response to environmental conditions, leading to colder conditions in the spring and warmer conditions in the fall as compared to unregulated systems. Breaching the dams would reverse these effects. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO EIS numerical water quality modeling. The EIS has undergone a third party neutral Independent Expert Peer Review on the tools used, as well as the assumptions and conclusions in the EIS.
6506	13	Columbia River Keepers	Columbia River Keepers	B. The summer water temperature regime in the free-flowing Lower Snake River would not be similar to that of reservoirs. The DEIS oft-repeated claim that water temperatures in June, July, and August would be similar30 with or without the dams is misleading and incorrect, even assuming that the Corps modeling of temperature in the free-flowing Lower Snake river is reliable. This claim appears to 24 DEIS, p. 4-32; see also id. at 1-45, 3-551, 6-42, 7-19, D-6-25, D-6-71. 25 DEIS Appendix D, Annex A, p. A-2-5. 26 DEIS Appendix D, p. D-6-31; see also id. at D-A-1-28 (showing even smaller differences when comparing monthly averages of daily average water temperatures). 27 DEIS Appendix D, p. D-6-36. 28 See, generally, Exhibit 8, EPA, Issue Paper 1: Salmonid Behavior and Water Temperature (2001). 29 DEIS Appendix D, p. D-6-25 (Explaining that During [May], total river flows are highest due to snowmelt (i.e. spring freshet), resulting in overall cooler water temperatures throughout the [free-flowing] lower Snake River as compared to the No Action Alternative.); see also id. at D-6-31. 30 DEIS, p. 4-32; see also id. at 1-45, 3-551, 6-42, 7-19, D-6-25, D-6-71. Columbia Riverkeepers FCRPS DEIS Comments - 12 be based exclusively on the Corps projections of daily maximum temperatures in the dammed and free-flowing Lower Snake River. Daily maximum temperature is just one of several water temperature parameters that influence how well adult salmon and steelhead migrate and survive. As detailed in Section V, below, other temperature parameters and metricsincluding average temperature, diel cooling, and inter-day variabilitywould all be different, and more favorable to salmon and steelhead, in the free-flowing river. Accordingly, dam removal would meaningfully improve the temperature profile of the Lower Snake in the summertime in ways that benefit salmon and steelhead. The DEIS blanket assertion that summer temperatures in the Lower Snake would be similar after dam removal is therefore misleading and incorrect.	The water temperature regime in the lower Snake River under a dam breach scenario would differ from the No Action Alternative. To evaluate the effects of water temperatures for each of the alternatives, the co-lead agencies used the daily maximum water temperature metric in the analysis because most state water quality standards are based on this metric. The water temperature analysis specific to MO3 (the dam breaching scenario) utilized the Dworshak CE-QUAL W2 (2-dimensional model) and the lower Snake River HEC-RAS (1-dimensional models) to predict water temperatures under a dam breach scenario, while incorporating operations at Dworshak Dam for downstream water temperature management. Specifically, Dworshak operations in 2016 (No Action) were used in the MO3 analysis. Results were utilized in the NMFS COMPASS and CSS modeling and other analysis to evaluate the impacts to anadromous fish. They were also used to qualitatively examine effects to fish species based upon known relationships between water temperatures and fish responses specifically for stocks such as sockeye salmon and fall Chinook salmon where quantitative models were not available. In this way, the co-lead agencies discussed the effects on time and locality scales that may not be detected by the models. Breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3 of the Draft EIS. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. The lower Snake River dams increase water particle travel times, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. The operation of Dworshak Dam may help to ameliorate some of the warm water temperatures in the lower Snake River. Regarding the assertion that the co-lead agencies ignore the fact that breaching the dams would improve fish migration is puzzling. Both models showed faster travel time and higher survival for outmigrating juveniles, while adult return abundance varied by model. Also, major increase in fall Chinook spawning habitat, and improved upstream migration conditions for all adults would be realized under a dam breaching scenario.
6506	14	Columbia River Keepers	Columbia River Keepers	Furthermore, the temperature model used to assess dam breaching appears to overestimate summer temperatures in the Lower Snake River.31 Problems and uncertainty with the Corps modeling further undercut the DEIS central narrative [e.g. that summer water temperatures would be the same with and without the Lower Snake dams] because the DEIS appears to over-estimate how hot the Lower Snake would be without the dams. The HEC-RAS model habitually over-predicts summer temperatures in the Lower Snake.32 But the Corps nevertheless asserts, without any real justification, that it expects HEC-RAS to accurately predict water temperatures without the dams.33 This makes no logical sense, and some important sources of modeling uncertainty contradict the Corps hope that HEC-RAS will somehow begin accurately predicting summer water temperatures under a dam-breach scenario. For instance, wind- and temperate-driven evaporative cooling is an important source of heat loss from the river, but the HEC-RAS model has no way to adjust the wind-sheltering coefficients or change evaporation rates seasonally.34 These limitations on the HEC-RAS model would likely still cause this model overpredict summer water temperatures in the free-flowing Lower Snake.35 Another indication that the Corps may be over-estimating summer temperatures in the free-flowing Lower Snake is that the Corps HEC-RAS model over-predicts summer water temperatures in the Lower Snake when compared to EPAs RBM-10 model.36 Accordingly, summer daily maximum temperatures in the free-flowing Lower Snake may actually be lower than the DEIS predicts. //// 31 See Exhibit 1, pp. 12. 32 DEIS Appendix D, Annex A, p. A-1-16 (the HEC-RAS representation of the current [i.e. dammed] system overpredicts mid-summer temperatures); id. at p. A-1-18 (explaining that HEC-RAS underpredicts [reservoir] water temperature consistently throughout the year except during the summer, at which time the temperature is overpredicted). 33 DEIS Appendix D, Annex A, p. A-1-18. (The WQ team believes these results corroborate the 360 HEC-RAS heat balance routines and the parameter set for a one-dimensional representation of 361 dam breach of the lower Snake River.); id. at p. A-1-16. 34 Exhibit 1, p. 1. 35 Id. 36 DEIS Appendix D, Annex A, p. A-1-28 (comparing results of HEC-RAS and RBM-10 modeling on free-flowing Lower Snake water temperatures). Columbia Riverkeepers FCRPS DEIS Comments - 13 C.	The commenter has not provided sufficient justification to support the assertion that "the temperature model used to assess dam breaching appears to overestimate summer temperatures in the Lower Snake River" or "the HEC-RAS model habitually over-predicts summer temperatures in the Lower Snake" and assertions in the paragraph are incorrect. Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). Please note that model calibration reports were developed for all water quality models and are available by request. In regards to HEC-RAS, this model does have a way to adjust the wind-sheltering coefficients but uses different terminology: wind coefficients a, b, and c. HEC-RAS does change evaporation rates seasonally because evaporation rates depend on temperature and wind speed, similar to the approach used in CE-QUAL-W2. As stated above, the co-lead agencies and USEPA worked collaboratively to compare RBM-10 and the CRSO EIS water temperature models and concluded that the temperature predictions by both models are within a reasonable estimate of the uncertainty bounds. Differences between model estimates should be viewed as a reflection of the uncertainty in the predictive accuracy of the available tools.
6506	15	Columbia River Keepers	Columbia River Keepers	C. Fall cooling in the free-flowing Snake River would be far more significant than spring warming, both in terms of absolute temperature differences and benefits to fish survival. The DEIS narrative incorrectly implies that predicted fall cooling in the free-flowing Snake River would roughly mirror, and offset, spring warming. This is misleading. The magnitude, duration, and ecological impact of predicted cooling in September, October, and November is far greater than the impact of any warming that might occur in March or April. In contrast to the spring months, when ranges of uncertainty are incorporated into the models results, fall temperatures in the free-flowing river are almost always lower than the dammed river.37 Furthermore, in	The EIS documents that the spring warming is less than extreme than the fall cooling when comparing MO3 (dam breach) to the No Action Alternative. Regarding water temperatures in the lower Snake River, it is well known that reservoirs create a lag in the thermal response to environmental conditions, leading to colder conditions in the spring and warmer conditions in the fall as compared to unregulated systems. Breaching the dams would reverse these effects. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO EIS numerical water quality modeling. The EIS has undergone a third party neutral Independent Expert Peer Review on the tools used, as well as the assumptions and conclusions in the EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				contrast to the minor differences between the dammed and free-flowing Lower Snake predicted for March and April, the significant differences in water temperature predicted in September and October would occur when the dammed river would be warm enough to cause migrating salmon and steelhead thermal stress. Steelhead and fall Chinook attempt to migrate through the Lower Snake mostly in September and October. According to EPA, migration temperatures for adult steelhead and fall Chinook are 1013 C and 10.619.4 C, respectively.38 Temperatures in the dammed Lower Snake are often above, or at the high end, of these ranges in September and October. Therefore, significant temperature reductions in September and October provided by dam removal would meaningfully improve migration conditions for steelhead and fall Chinook. Dam removal would also improve spawning temperatures, and success, for fall Chinook in the Lower Snake, especially in October and early November when the dammed river is often significantly warmer than the 10 C optimum spawning temperature or even the 15 C level considered stressful for spawning.39 In sum, the fall cooling predicted in a free-flowing Lower Snake River significantly exceeds the magnitude, and benefit to salmonids, of any spring warming that might occur due to dam removal; the EIS and, more broadly, the action agencies and NMFSshould stop implying that these two effects are equivalent and counterbalancing.	
6506	16	Columbia River Keepers	Columbia River Keepers	V. The DEIS Does Not Take a Hard Look at the Impacts of Lower Snake River Dam Removal on Water Temperature, Fish Migration, and Salmon Recovery. The DEIS blanket assertion that Adult upstream passage through the CRS projects on the lower Columbia and lower Snake Rivers is generally safe and effective40 is incorrect and deeply irresponsible. Columbia and Snake river dams routinely and significantly impair the upstream migration of adult salmon and steelhead, in large part due to the dams impacts on water temperatures in fishways and reservoirs. 37 DEIS Appendix D, Annex A, p. A-2-5. 38 Exhibit 9, EPA, Summary of Temperature Preference Ranges and Effects for Life Stages of Seven Species of Salmon and Trout, pp. A-3, A-4 (1998). 39 Exhibit 8, p. 17. 40 DEIS, p. 3-301 (note that the pagination of the DEIS erroneously jumps from 3-304 to 3-285 and then repeats upward, meaning that duplicate page numbers exist in that range). Columbia Riverkeepers FCRPS DEIS Comments - 14 The eight dams on the lower Columbia and Snake rivers have caused significant mortality of returning adult endangered Snake River sockeye41 in four of the past five years. The catastrophic and well-known fish kill in 2015 destroyed an estimated 96% of the endangered Snake River sockeye before they passed Lower Granite Dam, and EPA admitted that the death of these fish was attributable primarily to warm water.42 Unfortunately, subsequent years have shown that adult Snake River sockeye frequently die in significant numbers in the hydrosystem. In 2017, NMFS estimated that passage through the hydrosystem killed 43% of returning adult endangered Snake River sockeye.43 In 2018, NMFS estimated that 15% of adult Snake River sockeye died between the Bonneville and McNary dams;44 and ladder counts suggested that 28% of the remaining fish died in the Lower Snake.45 In 2019, ladder counts suggested 75% mortality for sockeye in the Lower Snake: 320 sockeye were observed at Ice Harbor Dam ladder, but only 81 were observed in the ladder at Lower Granite Dam.46 Unhelpfully, the DEIS only presents information on adult Snake River sockeye survival from 2012 through 201647 even though the current BiOp requires the action agencies to collect and report such reach mortality data every year.48 The overwhelming evidence suggests that the hydrosystem has caused very significant mortality on endangered Snake River sockeye in recent years particularly in the Lower Snake River. Adult Snake River steelhead and Chinook also suffer significant mortality from the hydrosystem. The DEIS suggests that (when eliminating other sources of mortality) only 85% of these fish survive their journey past the 8 dams.49 The DEIS does not explain why the action agencies believe that killing 15% of all pre-spawn adult fish from populations that are not meeting recovery objectives is safe and effective, or whether this level of mortality is acceptable, sustainable, or likely to lead to extinction. As explained below, these estimates of out-right fish mortality in hydrosystem do not capture the effects of chronic or cumulative thermal stress that may contribute to additional mortality or reproductive failure upstream of Lower Granite dam. The DEIS explicit dismissal of the impacts of the dams, and water temperatures, on adult salmon and steelhead survival and recovery constitutes a failure to take a hard look at an important problem. The following subsections provide a more thorough review of why the DEIS discussion of water temperature and salmonid migration is inadequate. 41 The DEIS uses the modeled SAR for Snake River spring/summer Chinook as a proxy for Snake River sockeye survival. This is inappropriate given the differences in return timing, temperature sensitivity, and conversion rates between adults of these two species. 42 Columbia Riverkeeper v. Pruitt, Case No. 2:17-cv-00289-RSM, Defendants Answer, 3 (May 15, 2017). 43 Exhibit 10, NMFS, 2019 adult survival estimates for distribution spreadsheet; SR Sockeye tab (2019) (excerpted from original). 44 Id. 45 Fish Passage Center, Adult Returns for Columbia & Snake River Dams Webpage (queried April 5, 2020). 46 Id. 47 DEIS, Table 3-113 on p. 3-302 (this table is mis-labeled). 48 NMFS, 2019 CRS Biological Opinion, p. 877 (March 29, 2019). 49 DEIS, p. 3-302. Columbia Riverkeepers FCRPS DEIS Comments - 15	The four lower Snake River and four lower Columbia River dams are equipped with adult fish ladders which are safe and effective for passing adult fish upstream, and adult salmon and steelhead passage is generally considered good through the lower Snake and Columbia rivers. For example, adult survival rates (adjusted to account for reported harvest and typical straying rates) for Snake River spring/summer Chinook salmon are relatively high, averaging about 89 percent between Bonneville and McNary Dams and 83 percent between Bonneville and Lower Granite Dams. These survival rates include "natural" mortality as well as any mortality associated with injuries incurred from predators because mortality cannot currently be assigned to a source. The co-lead agencies worked with cooperating agencies when developing strategies to utilize surrogate species when sufficient data was not available for life cycle modeling. Chapter 3 section 5 and Appendix E have more detail on the use of surrogate species. The co-lead agencies agree with your concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used current high quality information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. It is well understood that the CRS dams have an impact on natural riverine processes as well as anadromous fish migration. This is discussed throughout the EIS document. A system water quality model was developed to analyze water temperature and TDG effects throughout the Columbia River System for this EIS. Breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. The models showed minor changes in the Columbia River under this alternative, indicating that the operations of the CRS dams have a limited ability to reduce temperatures in the lower Columbia River. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. With respect to the Preferred Alternative, the fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals.
6506	17	Columbia River Keepers	Columbia River Keepers	A. The DEIS singular focus on daily maximum temperature, and 68 F, ignores many important, and complex, relationships between salmonids and water temperature. Although the DEIS focus on daily maximum water temperature, and particularly on the 68 F (20 C) mark, is appropriate for evaluating the water quality standards, it oversimplifies a multifaceted relationship between fish migration, fish health, and water temperature. Because the DEIS water quality modeling only predicted daily maximum temperatures, the DEISs analysis and discussion of those modeling results overlooks many of the differences in the temperature regimes that would occur in a dammed and free-flowing Lower Snake River. While instantaneous daily maximum temperature is relevant to salmonid survival (and can be controlling if, temperatures are extreme), the daily maximum is just one of several important temperature metrics that influence how well salmonids can migrate through the Lower Snake River.50 Furthermore, focusing on days above and below 68 F oversimplifies the state water quality criteria that the DEIS is purporting to address.51 The DEIS focus on daily maximum temperature obscures important consequences of Lower Snake River dam removal and does not constitute the hard look that NEPA requires. The DEIS singular focus on 68 F daily maximum temperatures is inappropriate because many negative impacts to salmonids occur at temperatures well below 68 F. These chronic temperature impacts can, and often do, lead to migration failure and premature mortality. As EPA explained with regard to sockeye, migration blockages, susceptibility to disease, impaired maturation, increases to stress parameters, reduced efficiency of energy use, and reduced swimming performance are all more common as daily mean temperatures exceed 62.6 F (17C).52 Similarly, NMFS noted that, At water temperatures above 64.4 F, [Snake River] sockeye salmon display increases in fallback and straying, and decreases in survival.53 In laboratory tests, all sockeye held at 68 F died after 12 days; but even sockeye held at 61 F showed significant thermal stress (weight loss, absence of fat reserves, enlarged liver, and reduced egg size) when compared to fish held at lower temperatures.54 Temperature impacts below 68 F are not limited to sockeye. Adult Chinook survive better when water temperatures remain below 57.2 F,55 and EPA found 66.9 F to be the upper feasible limit for fall Chinook 50 See Exhibit 11, EPA, Issue Paper 5: Summary of Technical Literature Examining the Physiological Effects of Temperature on Salmonids, p. 74 (2001) (Even if a free-flowing river experienced a maximum daily temperature that impeded upstream migration, it would not have continuous temperatures beyond the migration threshold, nor would they be present for many consecutive days.) 51 See Exhibit 1, pp. 23 (explaining how the DEIS approach to addressing state water quality criteria for temperature ignores the states natural conditions criteria, which limit additional thermal loads from anthropogenic sources, including dams, when waterways exceed the numeric temperature criteria). 52 See Exhibit 11, p. 74. 53 NMFS, 2019 CRS Biological Opinion, p. 600 (March 29, 2019). 54 See Exhibit 11, p. 78; see also Crossin, et al., Exposure to high temperature influences the behaviour, physiology, and survival of sockeye salmon during spawning migration, Canadian J. of Zoology, 86:12740 (2008) (explaining that wild adult sockeye collected and held for 24 days at 18 C were roughly twice as likely to die both during holding and during their subsequent spawning migration as sockeye held at 10 C). 55 See Exhibit 11, p. 76. Columbia Riverkeepers FCRPS DEIS Comments - 16 migration.56 Accordingly, the DEIS singular focus on 68 F as a proxy for adult salmonid migration success ignores the well-documented negative impacts of water temperature below this threshold and therefore does not constitute a hard look at an important problem. The DEIS singular focus on 68 F daily maximum temperature is also inappropriate because it does not address the negative impacts to reproductive success from warm water that occur well below 68 F. Even for salmon and steelhead that survive their migration through the hydrosystem, the extended exposure to elevated temperatures can compromise their ability to reproduce successfully for a wide variety of reasons, from pre-spawning mortality to poor fry condition in the next generation. As EPA explained regarding sockeye, [e]levated but sublethal temperatures are known to negatively affect secretion of the hormones controlling sexual maturation . . . [and t]he likely physiological consequences of these reduced hormone levels are poor spawning success, poor egg quality and viability, and senescent death prior to spawning.57 Hatchery observations of O. mykiss and Chinook also showed a variety of negative impacts on reproductive success (e.g. increased pre-spawn mortality; decreased sperm volume and viability; decreased egg size, fertility, and survival; and decreased embryo and juvenile survival) that generally intensified as pre-spawning water temperatures increased from 50 to 68 F.58 Observations of wild coho salmon also showed decreased egg viability and hatching rates for fish that encountered water above 59 F during their spawning migration.59 By focusing almost exclusively on the 68 F mark, the DEIS fails to explain, much less attempt to quantify, how the combination of sustained warmer water and increased migration time in the Lower Snake River reservoirs likely harms the reproductive success of all stocks of Snake River salmon and steelhead. The DEIS singular focus on 68 F daily maximum temperature also obscures the importanceto adult salmonid migration and, ultimately, reproductionof the increased daily temperature fluctuations that would occur in a free-flowing lower Snake River. The DEIS does admit that summertime daily temperature fluctuations would be roughly two to six times greater in a free-flowing	The co-lead agencies chose to use the daily maximum water temperature metric in the analysis because most state water quality standards for water temperature are based on this metric. The water temperature analysis used CE-QUAL W2 (2-dimensional model) and HEC-RAS (1-demesional models) to predict water temperatures under all alternatives. Results were provided to the fish team for incorporation into NMFS COMPASS and CSS modeling and other analysis to evaluate the impacts to anadromous fish. The fish team also used water quality outputs to qualitatively examine effects to fish species based upon known relationships between water temperatures and fish responses where quantitative models were not available. In this way the team was able to discuss effects on time and locality scales that may not be detected by the models. Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). The co-lead agencies and USEPA concluded that the temperature predictions by both models (CE-QUAL W2/RAS and RBM-10) are within a reasonable estimate of the uncertainty bounds. Differences between model estimates should be viewed as a reflection of the uncertainty in the predictive accuracy of the available tools.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Lower Snake River: modeling predicts that daily low temperatures in the freeflowing Lower Snake would be 2.5 to 3.5 F less than daily maxima, whereas daily cooling in the reservoirs would be just 0.5 to 1.0 F.60 However, the DEIS does not really describe the implications of this admissionnamely that, assuming similar daily maxima, the free-flowing Lower Snake would, throughout much of each summer day, be significantly cooler than dammed river. This severely undercuts the DEIS central narrative that summer water temperatures in the Lower Snake would be similar61 with or without the four dams. At most, the daily maximum summer temperatures in the Lower Snake with and without dams might be 56 See id. 57 Id. 58 See, generally, id. at pp. 7677. 59 See id. at p. 77 (May 2001). 60 DEIS, p. 3-270; see also id. at D-6-37 (Figure 6-29, showing modeled daily temperature fluctuations that would occur without the four Lower Snake Reservoirs). 61 DEIS, p. 4-32; see also id. at 1-45, 3-551, 6-42, 7-19, D-6-25, D-6-71. Columbia Riverkeepers FCRPS DEIS Comments - 17 similar. But the temperature regime that fish experience throughout each day in the dammed versus free-flowing Lower Snake would be quite different, and more favorable to migration, because the undammed river would often cool 2 to 3 F throughout each 24-hour period.62 As EPA noted, even if the free-flowing [Lower Snake] river experienced a maximum daily temperature that impeded upstream migration, it would not have continuous temperatures beyond the migration threshold, nor would they be present for many consecutive days.63 By overemphasizing daily maximum temperatures and largely ignoring the much greater daily cooling that would occur in the free-flowing Lower Snake, the DEIS incorrectly concludes that summer temperatures, and salmon migration conditions, would be similar in the dammed and freeflowing rivers. The DEIS singular focus on daily maximum temperature also obscures the significant differences between average summer water temperatures in the dammed and free-flowing Lower Snake. Contrary to the DEIS repeated assertion that summer temperatures in the Lower Snake would be similar64 with or without the four dams, modeling by Columbia Riverkeeper using the EPAs RBM-10 temperature model (below) shows that daily average temperatures in the Lower Snake River during the summer of 2015 would have actually been significantly lower than daily average temperatures in the dammed river.65 The Corps HEC-RAS model produced similar results for summer 2015.66 The Corps could and should have used HEC-RAS, which uses an hourly timestep, to comprehensively to model the daily minimum and daily average temperatures that would result from dam removalalongside the daily maxima. The results of such a modeling effort would have given readers of the DEIS a much more robust and 62 DEIS, pp. 3-270, D-6-37. 63 See Exhibit 11, p. 74. 64 DEIS, p. 4-32; see also id. at 1-45, 3-551, 6-42, 7-19, D-6-25, D-6-71. 65 Exhibit 12, Columbia Riverkeeper, White Paper: Computer modeling shows that Lower Snake River dams caused dangerously hot water for salmon in 2015, p. 4 (2017). 66 DEIS, Appendix D, Annex A, p. A-1-28. Columbia Riverkeepers FCRPS DEIS Comments - 18 meaningful picture of how dam removal would impact temperature and salmonid migration. Instead, the Corps focused its modeling effort exclusively on daily maximum temperatures, an oversight that led directly to the DEIS misleading narrative that summer water temperatures would be similar in the dammed and free-flowing Lower Snake. Compounding this error, the DEIS provides almost no explanation of how the lower average and minimum daily temperatures that would occur in the free-flowing Lower Snake would benefit survival and reproductive success of summer-migrating adult salmonids. Altogether, the Corps singular focus on modeling daily maximum temperatures results in a DEIS that gives the incorrect impression that Lower Snake Dam removal would not improve summer water temperatures or migrating conditions for adult salmonids.	
6506	18	Columbia River Keepers	Columbia River Keepers	B. Lower Snake River dam removal could decrease cumulative thermal stress on adult salmon and steelhead by shortening migration times. The DEIS should have examined how removing impediments to migration in the Lower Snake River could decrease cumulative thermal stress and improve adult salmon migration, survival, and reproduction. Even if the DEIS narrative that summer water temperatures would be similar with and without the Snake River dams was true (and it is not), salmon and steelhead migrating through the dammed and undammed rivers would likely experience significantly different amounts of thermal stress. This is because migrating adult salmon and steelhead experience thermal stress cumulatively,67 and the dams, fishways, and reservoirs create migration blockages that likely cause adult fish to spend more days lingering in warm water.68 Fish forced to hold in warm water expend significantly more metabolic energy just to survive, and, because migrating adult salmon do not feed and have a finite amount of stored body energy,69 increasing the duration of exposure to warm water can drain energy stores and lead to negative outcomes for survival and reproduction.70 Accordingly, the DEIS should have compared adult fish passage times through the dammed Lower Snake River to projected passage times through the free-flowing river and discussed the implications for migration, latent mortality, and reproductive success. The discussion of temperature is incomplete without an acknowledgement 67 See Exhibit 13, Lisa Crozier, Impacts of Climate Change on Salmon of the Pacific Northwest, p. 18 (2015) (explaining that cumulative thermal stress is the primary predictor of migration survival in endangered Snake River sockeye adults). 68 See Exhibit 11, p. 78 (Explaining that [f]orced delays in spawning, such as are frequently caused by difficulties in passing dams, can cause decreases in reproductive success.); see also NMFS, 2019 CRS Biological Opinion, p. 601 (noting high rates of sockeye fall back and consequent migration delays at Lower Granite, The Dalles, and Bonneville dams); see also Exhibit 14, David Cannamela et al., Letter to Northwest Policymakers re: Science-based solutions are needed to address increasingly lethal water temperatures in the lower Snake River (October 22, 2019). 69 See, Exhibit 11, p. 75. 70 Exhibit 15, Keefer, et al., Thermal exposure of adult Chinook salmon and steelhead: Diverse behavioral strategies in a large and warming river system, PLoS ONE 13(9), pp. 1617 (2018) (Warm conditions more rapidly exhaust finite energetic reserves, which salmon and steelhead are simultaneously re-allocating to sexual maturation and depleting during migration, holding, and spawning. At the same time, stress hormone production surges, organs atrophy, and immune function is substantially reduced. These co-occurring processes allow the proliferation of parasites and pathogens, many of which become more virulent as temperatures rise, significantly increasing the likelihood of premature mortality.). Columbia Riverkeepers FCRPS DEIS Comments - 19 that the dams and fishways create migration delays that likely subject migrating adults to more cumulative thermal stress than they would experience in a free-flowing river. This is another example of how the DEIS singular focus on daily maximum water temperature obscures and minimizes the benefits of Lower Snake River dam removal for water temperature and salmon recovery.	It is well known that reservoirs create a lag in the thermal response to environmental conditions, leading to colder conditions in the spring and warmer conditions in the fall as compared to unregulated systems. Breaching the dams would reverse these effects. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. The co-lead agencies agree that reductions in fall water temperatures under MO3 would be beneficial and more significant than any early spring warming that would occur. Water temperature reductions in September and October would meaningfully improve migration conditions for steelhead and fall Chinook in the lower Snake River. These considerations are reflected in the modeling results for steelhead and are discussed qualitatively for Snake River Fall Chinook salmon. The Draft EIS (Page 3-567) concludes that the temperature differences under MO3 would reduce straying and migration delays and disease susceptibility that would improve survival and spawning success of Fall Chinook and coho salmon. Likewise, the analysis for sockeye salmon (Page 3-565) discusses the trade-offs between increased stress potential with warmer spring/summer daytime temperatures and the potential benefits from reduced delays, decreased thermal exposure, reduced straying and fallback due to not being transported as adults, and reduced fallback due to fish ladder temperature differentials. This information was incorporated into the cumulative effects analysis for MO3, which includes the breaching the four lower Snake River dams. See Section 6.3.1.3 for Water Quality impacts under MO3 and 6.3.1.4 for Anadromous Fish impacts under MO3.
6506	19	Columbia River Keepers	Columbia River Keepers	VI. The DEIS does not take a hard look at the implications of climate change for water temperatures and salmonid survival. The DEIS does not take a hard look at how impending climate change will impact river temperatures.71 Climate change has led to increased water temperatures throughout the hydrosystem;72 various studies show that the monthly average August temperature of the Columbia at Bonneville Dam is increasing at .2 to .4 C per decade73 and could warm by a cumulative 1.7 to 2 C by the end of the century.74 Despite this significant threat to water quality and fisheries, the DEIS does not take the logical step of modeling how climate change will impact river temperatures at various points throughout the hydrosystem in coming decades. Indeed, the RMJOC model that the DEIS uses to discuss climate change could have produced the necessary inputs (i.e. predicted air temperate, precipitation, streamflow, etc.) to run the water temperature models under predicted climate conditions for the coming decades.75 The failure to model potential future water temperatures throughout the hydrosystem not only prevents the DEIS from taking a hard look at a looming problem, it cuts short any discussion of what measures might be necessary to ensure that salmon and steelhead can still endure their migration through the warming rivers in coming decades.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4).
6506	20	Columbia River Keepers	Columbia River Keepers	The DEIS should have considered new strategies to mitigate the effects of climate change on river temperatures. Not only is new temperature mitigation necessary to ensure that salmon and steelhead can safely migrate through the hydrosystem as climate change intensifies, it is appropriate because the reservoirs actually intensify the water temperature increases caused by changing climate.76 In other words, the impacts of climate change on water temperature (and, by extension, fish survival77) in the current hydrosystem are worse than they would be in a freeflowing river. Nevertheless, the DEIS does not explore or recommend strategies to deal with increasing water temperatures under climate change. An appropriate exploration of temperature mitigation actions would have included, at least, studying: increased summer flow from Canadian storage reservoirs; increased and/or variable-depth releases from Grand Coulee dam; 71 See, e.g., DEIS, p. 4-31; see also Exhibit 1, pp. 34. 72 See generally Exhibit 16, EPA, Draft Assessment of Climate Change Impacts on Temperatures of the Columbia and Snake Rivers (2018). 73 Exhibit 17. EPA, Columbia & Snake River Temperature TMDL: Preliminary Technical Information PowerPoint Presentation, Slide 28 (August 29, 2018). 74 Exhibit 6, Slide 53. 75 See Exhibit 1, pp. 34. 76 Exhibit 17, Slide 31 (showing that average August temperatures at John Day dam are increasing faster in the dammed river than they would without the dams). 77 See, generally, Exhibit 13. Columbia Riverkeepers FCRPS DEIS Comments - 20 summer-time drawdown of McNary and John Day pools or the removal of these dams; and the draw-down or removal of Snake River dams coupled with optimizing Dworshak cold water releases to enhance fish migration. The failure to contemplate, much less recommend, any mitigation for the intensifying water temperature problems caused by the dams and climate change (especially in the main-stem Columbia River) is inexcusable and short-sighted.	The Draft EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives' effects on Snake River stocks, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Regarding climate change, the climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at the resolution required at this time. Therefore it was not possible to reliably model water temperature changes under climate change for this EIS (river vs. regional or global scale). In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3). Regarding water temperatures under dam breach scenarios, the analysis of MO3, which includes breaching the four lower Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action Alternative conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The models showed minor changes in the Columbia River under this alternative. The fish benefits of breaching the Snake River dams is discussed in the analyses of Snake River salmon and steelhead in the Draft EIS. Faster travel times, among other parameters such as temperature differences, under a breach scenario were incorporated into both models that were used to estimate juvenile survival and, as reported in the Draft EIS, both indicated higher juvenile survival than the No Action Alternative. For Snake River Spring/Summer Run Chinook Salmon, decreased travel time of 4.5 days and 5.5 days, respectively, were indicated by CSS and COMPASS models, compared to the No Action Alternative. The Preferred Alternative includes a combination of measures that meet the Purpose and Need and objectives of the Columbia River System Operations (CRSO) EIS, while balancing the authorized purposes of the 14 Federal dam and reservoir projects that make up the CRS. The temporal scope of the EIS is assumed to be 25 years from the signing of the Record of Decision (ROD) in order to have a similar period of analysis for comparison of effects across resources for all multiple objective alternatives. While the Preferred Alternative was developed largely focused on the analysis based on historical and synthetic hydrology, climate change data was also considered. Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for the Preferred Alternative. With the uncertainty associated with climate change, it is important that we establish methods for adapting and increasing flexibility on the system. There are measures in the Preferred Alternative that are adaptive to emerging changes in climate and ensure there is flexibility to respond to future changes. One example of this is the habitat restoration program that counters increased stream temperature with deeper pools and more shaded areas.
6506	21	Columbia River Keepers	Columbia River Keepers	Scientific basis of modeling 1. CE-QUAL-W2 (W2) is an appropriate and robust model for modeling reservoirs. Unfortunately, there are significant gaps in information regarding how the model was developed for the DEIS. a. I have been unable to find any information or citations to the calibration of the	Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				model or other model quality assessment analyses. The DEIS provides one calibration statistic, but the method of calculation is not provided. Typically, model quality assessment is demonstrated with a detailed analysis of calibration metrics and other methods such as validation, uncertainty analysis, and sensitivity analysis. b. It is unclear how model output was structured, or how results were averaged or analyzed in other ways. c. CE-QUAL-W2 can be used for free-flowing rivers. It is unclear how much effort went into testing W2 for this application before it was abandoned in favor of HEC-RAS. 2. The modeling of the Snake River with HEC-RAS for the MOS3 free-flowing scenario is described in Annex A of Appendix D. This model appears to have significant flaws for modeling the Snake River. I have several concerns about the information provided and appropriateness of the analysis. a. The DEIS provides inadequate information about the framework or calibration of the HEC-RAS model. Again the DEIS should provide more detailed information about parameter selection and model quality metrics. b. The report points out several problems with the use of HEC-RAS for the Snake River. They admit that the model calibrates poorly and point to several causes. First, unlike W2, HEC-RAS has no wind sheltering coefficient. Wind-driven evaporation can be a major factor in accurately describing temperature regimes in reservoirs and wide rivers. HECRAS has several other wind coefficients, and the sensitivity analysis they provide indicates that this is a critical parameter. Yet it is unclear how the coefficients are used in calibration and the difference between these coefficients and a wind-sheltering coefficient. DRAFT - CRSO DEIS Comments Page 2 of 4 Paul Pickett, 8 April 2020 Second, HEC-RAS has no method to adjust evaporation seasonally. As a result, water temperatures in the model results are too high in summer and too low in winter. The report states that the HEC-RAS model is believed to corroborate the HEC-RAS heat balance routines and the parameter set for a one-dimensional representation of a dam breach bathymetry. However, the problems they identify earlier in the discussion contradicts this statement. If the problems with evaporation and wind sheltering are seen with the reservoirs, they will likely affect the free-flowing too. The free-flowing river is still wide, and will still have seasonal variation. They are hopeful that uncertainty swings their way, but the evidence they supply does not support their statement. c. To summarize the problems with model uncertainty: 1) The HEC-RAS undammed river model calibrates poorly, so the results are uncertain. The evidence provided suggests that it might be overpredicting water temperatares in summer. 2) The W2 model also has inherent uncertainty, and how results are averaged for comparison to the HEC-RAS model adds to uncertainty. 3) The uncertainty of both models is compounded when they are compared to each other. If HEC-RAS is overpredicting temperature, then the impacts of the impoundments on water temperature may be worse than the DEIS estimates. For the protection of the environment, this uncertainty should be evaluated, a range of impacts estimated, and conclusions drawn from the more severe estimates of impacts.	models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). Please note that model calibration reports were developed for all water quality models and are available by request. In regards to HEC-RAS, this model does have a way to adjust the wind-sheltering coefficients but uses different terminology: wind coefficients a, b, and c. HEC-RAS does change evaporation rates seasonally because evaporation rates depend on temperature and wind speed, similar to the approach used in CE-QUAL-W2.
6506	22	Columbia River Keepers	Columbia River Keepers	Use of the model to assess Water Quality Standards (WQS) 3. The DEIS is inconsistent in identifying where Section 303d impairments exist and where draft TMDLs have or will be developed. These facts are noted in some sections but not in others. This creates confusion and seems to misstate the relationship of the DEIS to the Clean Water Act and State water quality programs. 4. The DEIS misstates and misuses the Water Quality Standards (WAC 173-201A in Washington). a. Some of this confusion is indicated by the misuse of the term standards when actually referring to the criteria in the standards. The Water Quality Standards are the entire regulation, with a variety of elements such as criteria, designated uses, anti-degradation, natural conditions. b. Compliance with the criteria is only on part of compliance with the WQS. For rivers like the Columbia and Snake, the natural conditions provisions often apply. Natural conditions is defined in the standards as absent human-caused pollution, and in the case of this DEIS is represented by the free-flowing river modeling scenario. For temperature, either the criteria should be met, or if natural conditions are within 0.3 degrees C of the criterion or higher, thermal load cannot be added to the river that increases temperatures by more than 0.3 degrees C. 5. The effects of the dams are only illustrated at the dams themselves. The DEIS should show an analysis that evaluates all parts of the river and identifies the locations that have the greatest temperature impairment. 6. Just as the DEIS should identify actions that need to be taken to restore endangered species, actions should also be identified to comply with water quality standards. The analysis of water quality that compares the No Action Alternative (NAA) to other alternatives is not a valid assessment of DRAFT - CRSO DEIS Comments Page 3 of 4 Paul Pickett, 8 April 2020 compliance with the standards. At best this approach only shows if alternatives allow greater or lesser impairment, not the level of compliance with the standards. 7. This shortcoming is particularly evident in the Impact Framework and Decision Criteria. The narrative and illustrations provide little explanation of how criteria were developed, and overall appear to be arbitrarily chosen. They do not align with water quality standards, and no information is provided to demonstrate that they are significant from the perspective of salmon biology.	The EIS focused on the numeric water temperature criteria (20c) as a method to determine how alternatives would impact river temperature as compared to the No Action Alternative in accordance with NEPA regulations. The effects of the dams are specifically discussed in the affected environment sections of the EIS and are part of the existing condition. The temperature TMDL is being developed by the USEPA, as per their authority under the CWA, will include a full analysis of the impact of all anthropogenic and natural impacts on river temperatures, with the CRS dams being a part of that analysis. The TMDL will determine what temperature reductions are needed to meet state water quality standards across the basin. For more information on the newly issued TMDL for temperature for the Columbia and lower Snake rivers can be found at https://www.epa.gov/columbiariver/tmdl-temperature-columbia-and-lower-snake-rivers. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species' survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species.
6506	23	Columbia River Keepers	Columbia River Keepers	8. Comparing temperature and DO levels in a free-running river to those in a reservoir is challenging. Robust methods have been developed to compare conditions in the two water bodies using cumulative frequency distributions. Examples can be found in Willamette River TMDLs and the draft Pend Oreille River TMDL. These methods avoid errors in comparing scenarios with different travel times, while also pooling data in a way that is relevant to salmon habitat.	The co-lead agencies chose to use a process-based model to predict impacts to dissolved oxygen rather than empirical models that may have little relevance to the system. When applied correctly, process or physically based models better capture impacts from changing conditions than empirical models that are developed based on existing conditions.
6506	24	Columbia River Keepers	Columbia River Keepers	9. The comparison of the W2 modeling in the NAA to the HEC-RAS model in MO3 may introduce biases that downplay the differences. Annex A notes that HEC-RAS tends to over predict temperature. At the same time, its unclear how W2 analyzes temperature for comparison. If the W2 analysis provides water temperature results that vary in accuracy, and these are then compared to HEC-RAS results that overpredict temperatures, the result would be an inaccurately low difference between the two scenarios. a. Running the HEC-RAS for the reservoirs and comparing results with W2 for the reservoirs should suggest ways to account quantitatively for these differences. Also, statistical tools like cumulative distributions might be useful.	The reference to the HEC-RAS overprediction of water temperatures (in Annex A) was part of an evaluation of the use of a one-dimensional model under current conditions and is not related to the accuracy of the MO3 water temperature predictions. There is no evidence that HEC-RAS overpredicts water temperatures for the MO3 Alternative. Additionally, both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059).
6506	25	Columbia River Keepers	Columbia River Keepers	Characterization of the rivers with model results 10. The DEIS makes broad statements about water quality in the study area, but rarely do they provide quantitative evidence or citations to back the statements. This falls short of the level of scientific communication that one would expect from a document of this significance and technical detail. 11. Evidence or citations should be provided to show that data and modeling information used in the DEIS met data quality standards. Quality assurance and quality control (QAQC) plans are typically required of federal studies (they certainly are for State studies). The absence of QAQC information is at best poor science communication, and may also represent a violation of federal laws for data quality.	The level of detail provided in the EIS is sufficient to adequately describe the effects of the alternatives on water quality in comparison to the No Action Alternative, as required in the NEPA regulations. In addition to the information contained in Section 3.4 and Section 7.7.3 pertaining to water quality, additional information can be found in Appendix D. Model calibration reports were developed for all water quality models and are available by request. Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). The co-lead agencies developed a Quality Assurance Project Plan related to the models used in the EIS. The EIS has also undergone third party neutral Independent External Peer Review.
6506	26	Columbia River Keepers	Columbia River Keepers	Evaluation of Climate Change 12. Its good to see the discussion of the RMJOC-II Part 1 findings. However, the footnote on page 4-2 is disturbing (The co-lead agencies expect this study [Part 2] to be published in spring 2020 after release of the draft EIS and will review the study to determine if any information presented in the draft EIS needs to be updated.) The Part 2 study provides projections for flows in the current system for future climate change scenarios. If the Part 2 study is close to being published, preliminary results should be available. With the huge investment in RMJOC-II, and the quality and significance of the results, its essential that the Part 2 results be included in the DEIS. It is of vital importance to evaluate the relative impacts of climate change on the existing system of Snake River dams versus the MO3 option of dam breaching using the best available science. Both the RMJOC-II DRAFT - CRSO DEIS Comments Page 4 of 4 Paul Pickett, 8 April 2020 Part 1 and Part 2 results must be applied to the water quality modeling to evaluate future water temperatures for all Alternatives. 13. Results presented in the DEIS from the RMJOC-II Part 1 report are not consistent with the information found in the Part 1 report. Either the DEIS is in error, or different results have been selected for the DEIS than were published in the Part 1 report. Without explanation, this opens the DEIS to the appearance of cherry-picking data to support a preferred message. 14. The discussion in Section 4.2.3.3 regarding climate impacts on the MO3 alternative (Snake River dam breach) is inadequate and misleading. Little evidence is provided to support their assertion about climate impacts on the free-flowing river, and the discussion points to the effect of climate change on the free-flowing river while saying little about the relative impact of climate change on MO3 versus the other alternatives. This is all the more reason that the RMJOC-II results from both Part 1 and 2 need to be applied to water quality models to quantify impacts of all alternatives in a warming future.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS.
6506	27	Columbia River Keepers	Columbia River Keepers	Comparison of HEC-RAS to RBM10 free-flowing model 15. The comparison of these two models in Annex A suggests some differences that affect the temperature results: a. The channel geometries and flow characteristics are different. HEC-RAS directly models flow, and they altered the geometry to 1934 conditions. RBM10 used 2010 geometry and they note that they did not alter geometry to the likely change to free-flowing conditions. This could affect temperatures from differences in water depth and width. b. RBM10 uses regional meteorology data from major airports. HECRAS uses local met data. This may be a significant source of error. The airport met stations are far from the river, and data from these locations may be different from local temperatures and wind velocities along the Snake River. This would be especially significant for wind, since that drives evaporation and is a major factor on large rivers and reservoirs.	Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). Please note that model calibration reports were developed for all water quality models and are available by request. In regards to HEC-RAS, this model does have a way to adjust the wind-sheltering coefficients but uses different terminology: wind coefficients a, b, and c. HEC-RAS does change evaporation rates seasonally because evaporation rates depend on temperature and wind speed, similar to the approach used in CE-QUAL-W2. As stated above, the co-lead agencies and USEPA worked collaboratively to compare RBM-10 and the CRSO EIS water temperature models and concluded that the temperature predictions by both models are within a reasonable estimate of the uncertainty bounds. Differences between model estimates should be viewed as a reflection of the uncertainty in the predictive accuracy of the available tools.
6506	28	Columbia River Keepers	Columbia River Keepers	Global 1) Throughout the EIS and appendices, the term standards is misused. The standards are the entire state regulation. Often the text refers to the criterion, but calls it the standard. Please revise the document to make sure that standard only applies to references to the entire rule, while criterion refers to the specific numeric target.	The co-lead agencies used the numeric criteria as short-hand to refer to the standard criteria that applies to the specific geography, time period, etc. specified in the water quality standard. This short-hand does not include antidegradation or natural condition. The co-lead agencies chose to use the daily maximum water temperature metric in our analysis because most state water quality standards for water temperature are based on this metric. The document was revised for clarity.

6506	29	Columbia River Keepers	Columbia River Keepers	Appendix D - Body 1) Lines 1085-1086: Numerical modeling is needed to quantify temperature impacts from the dams addressed in this DEIS. According to a footnote in Chapter 4, a Part 2 study is close to being published. If so, preliminary results should be available. With the huge investment in RMJOC-II, and the quality and significance of the results, its essential that the Part 2 results be used to develop water temperature models of the Alternatives. The RMJOC-II Part 1 results are already available and could be applied to the modeling described in Annex A. However, for comparison, all of the Alternatives should be modeled for future impacts under climate change scenarios. It is of vital importance to evaluate the relative impacts of climate change on the existing system of Snake River dams versus the MO3 option of dam breaching using the best available science. Both the RMJOC-II Part 1 and Part 2 results must be applied to the DEIS analysis to provide an analysis that is comprehensive and up-to-date.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS.
6506	30	Columbia River Keepers	Columbia River Keepers	2) Lines 1136: list the Tribes with water quality standards in the Study Area (Spokane, Colville, Nez Perce)	Tribal Water Quality Standards are noted throughout the EIS where applicable.
6506	31	Columbia River Keepers	Columbia River Keepers	3) Lines 1138-1194: although the models used for this analysis (CE-QUAL-W2 and HEC-RAS) are described in a general way, no information or references are provided to describe the model development. This is a serious flaw information on the parameterization of the model and model quality assessment (calibration, validation, uncertainty or sensitivity analysis) is inadequate. As a result, there is no way to assess the quality and credibility of the modeling. This is both inconsistent with scientific modeling principles and likely also not in compliance with state and federal laws for the use of credible data in environmental decision-making.	Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). The co-lead agencies and USEPA concluded that the temperature predictions by both models are within a reasonable estimate of the uncertainty bounds. Differences between model estimates should be viewed as a reflection of the uncertainty in the predictive accuracy of the available tools. Please note that model calibration reports were developed for all water quality models and are available by request.
6506	32	Columbia River Keepers	Columbia River Keepers	4) Lines 1170, 1174, 1182: temperature metrics air or water temperature? Please clarify.	As described in the sentence preceding these lines, a five-year period (20112015) that represent a wide range of environmental response to hydrology (wet, dry, average) and weather conditions (hot, cold, average) were selected to model each EIS alternative against. Temperature metrics in this section refer to the weather conditions (hot, cold, average air temperatures). This has been added to the text for additional clarification.
6506	33	Columbia River Keepers	Columbia River Keepers	5) Lines 1177, 1180: water temperature response was near average unclear, response to what? How analyzed model or statistical?	Water temperature response was near average as compared to the period of record data that was used to select the five-year data set to run through the water quality model. The water temperature analysis used CE-QUAL W2 (2-dimensional model) and HEC-RAS (1-dimensional models) to predict water temperatures under all alternatives. Additional information can be found in the model calibration report, which is available upon request.
6506	34	Columbia River Keepers	Columbia River Keepers	6) Lines 1199-1201: Using CE-QUAL-W2 for free-flowing rivers is possible but difficult. But it would be better to use the same model for comparison of undammed to dammed.	The co-lead agencies evaluated the possibility of using CE-QUAL W2 for MO3, but concluded that HEC-RAS was an appropriate approach for water temperature modeling under a dam breach scenario and free-flowing river system. W2 captured the thermal dynamics of the reservoirs quite well under most CRSO alternatives but became quite unstable when applied to the lower Snake River as a riverine reach; and, due to the fact that well-mixed thermal conditions would be expected under a dam breach scenario, using a 2-dimensional model like W2 was not as necessary.
6506	35	Columbia River Keepers	Columbia River Keepers	7) Lines 1213 (Table 2-1): a) Hourly time step and daily maximum is more appropriate for assessing compliance with the WQS. b) Was channel geometry changed between free-flowing and dam scenarios? This introduces an additional source of uncertainty that should be checked. Differences in depth and velocity could affect temperature predictions.	The co-lead agencies used hourly timesteps to evaluate daily maximum water temperature for comparison to water quality standards. For MO3, the co-lead agencies used pre-dam channel bathymetry to predict water temperatures under a dam breach scenarios. The quantification of uncertainty due to bathymetry is beyond the scope of this EIS.
6506	36	Columbia River Keepers	Columbia River Keepers	8) Lines 1287: Why were these temperature change values chosen?	The co-lead agencies offer one way of organizing the EIS water temperature and TDG results, but other techniques could be used. The methodology the co-lead agencies chose was used to designate results into negligible, minor, moderate or major categories based on the absolute change in water temperature, number of days that water temperatures exceeded state water quality standard, and seasonality of change (based on whether anadromous fish are present or not). This methodology was reviewed by NMFS. In general, metrics were chosen based on: (1) absolute change in water temperature that the team considered to be measurable; (2) change in the days that water temperature standards were exceeded that was determined to be more related to the EIS Alternatives than seasonal/climatic variability. Hourly water temperature results for each five-year simulation are also provided in Appendix D.
6506	37	Columbia River Keepers	Columbia River Keepers	9) Lines 1288-1290: changes in days of non-compliance, pooled by month or season, is a reasonable metric. However the seasons chosen are not described.	Season are defined as: winter = December - February; spring = March - May; summer = June - August; and fall = September - November. This information has been added to Appendix D for clarity.
6506	38	Columbia River Keepers	Columbia River Keepers	10) Lines 1306 (Figure 2-3): a) The Impact Framework and Decision Criteria seem arbitrary. b) The criteria for negligible, minor or moderate is unclear and seems arbitrary. c) The key metric for the assessing the temperatures should be applying by the State water quality standards: the number of days and magnitude of increases over the criterion when natural (free-flowing) is below the criterion, or greater than 0.3 over natural when natural is above or within 0.3 of the criterion.	As is typical in NEPA documents, the co-lead agencies described effects as negligible, minor, moderate or major categories. These descriptions were based on the absolute change in water temperature, number of days that water temperatures exceeded state water quality standard and seasonality of change (based on whether anadromous fish are present or not). In general, metrics were chosen based on: (1) absolute change in water temperature that the team considered to be a measureable; (2) change in the days that water temperature standards were exceeded that was determined to be more related to the EIS alternative than seasonal/climatic variability. Hourly water temperature results for each five-year simulation are also provided in Appendix D.
6506	39	Columbia River Keepers	Columbia River Keepers	11) Lines 1293-1301: TDG decision criteria seem arbitrary and inappropriate. TDG hurts fish on a short time scale, not as a five year average. Change in the number of days with values over 115, 120, and 125 would be more appropriate.	Change in the number of days that TDG results exceed specific thresholds (110%, 115%, 120%, etc.) can be found in Appendix D for each EIS alternative. Our summary metrics are documented as well to provide a single impact level summary for the system. As is typical in NEPA documents, the co-lead agencies described effects as negligible, minor, moderate, or major. This was based on the absolute change in TDG per season and per year and then averaged for all five years. Hourly TDG results for each five-year simulation are also provided in Appendix D.
6506	40	Columbia River Keepers	Columbia River Keepers	12) Lines 1307-1331: Discussion of uncertainty is fairly general, but descriptions of issues seem appropriate.	Thank you for your comment.
6506	41	Columbia River Keepers	Columbia River Keepers	13) Lines 1335-1338: DO and pH can have a significant effect on metals in sediment. Whether this is minor is debatable, and depends on the ranges of those values occurring in the reservoirs.	Yes, this is true; such processes can be very complex and difficult to predict.
6506	42	Columbia River Keepers	Columbia River Keepers	14) Lines 1418-1421: There is also a draft TMDL for temperature in the Pend Oreille River, which is affected by Albeni Falls Dam operations.	This list included in the text is not intended to be a full, complete list of all TMDLs. The co-lead agencies mention the Albeni Falls water temperature TMDL in Appendix D, Section 3.1.1.2.
6506	43	Columbia River Keepers	Columbia River Keepers	15) Lines 1440-1444: there are court decisions related contributing or increasing a contribution to 303d impairments. This paragraph is not an accurate description of the situation (problems would continue until the sources of impairment are addressed.) The dams have been identified as sources of impairment, and the EIS should address whether the alternatives increase or decrease impairment.	The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 C.F.R. 1502.14) and is used for comparing the environmental effects of the other alternatives. The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change from 2016, which was the start of the EIS. The EIS focused on the numeric water temperature criteria (20c) as a method to determine how the alternatives would impact river temperature when compared to the No Action Alternative. The effects of the dams are specifically described in the Affected Environment sections of the EIS as required by NEPA. The temperature TMDL that was recently issued by the USEPA, as per their authority under the CWA, will include a full analysis of the impact of all anthropogenic and natural impacts on river temperatures, with the CRS dams being a part of that analysis. The TMDL will determine what temperature reductions are needed to meet state water quality standards across the basin. For more information on the TMDL for temperature for the Columbia and lower Snake rivers can be found at https://www.epa.gov/columbiariver/tmdl-temperature-columbia-and-lower-snake-rivers.
6506	44	Columbia River Keepers	Columbia River Keepers	16) Lines 1586-1598: The discussion of stratification (and other discussions that follow) should provide citations and quantitative metrics to back the descriptions provided.	The co-lead agencies added citation to the document to address this comment.
6506	45	Columbia River Keepers	Columbia River Keepers	17) Lines 1599-1603: The changes in temperature from tailwater to tailwater are not a useful or valid assessment of temperature impacts. Temperatures should be compared to a free-flowing river model to quantify the impacts of the NAA.	As stated in the Purpose and Need Statement in Section 1.2, the ongoing action that requires evaluation under NEPA is the long-term coordinated operation and management of the CRS projects for the multiple purposes. As mentioned in the Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulation, in the case where there is an ongoing management program or plan, the No Action Alternative would be "no change" from current management program or plan. The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 C.F.R. 1502.14) and provides a benchmark for comparing environmental effects of the other alternatives. The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change from operations in 2016 at the start of the EIS. The co-lead agencies used the standard points of compliance (fixed monitoring stations) that are located in the forebay and tailwater of each dam for the analysis, as these are the monitors used to guide real-time operations and ensure compliance with water quality standards.
6506	46	Columbia River Keepers	Columbia River Keepers	18) Lines 1599-1625: a) The entire river should be assessed, including the reservoirs, not just the dam locations. b) Data could be pooled by reservoir reaches and by month to compare with cumulative distributions.	The co-lead agencies agree and did evaluate the reservoirs. The co-lead agencies used the up-to-date, high quality information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. Water quality analysis completed for this EIS used a combination of numerical models (CE-QUAL W2 and HEC-RAS), past studies and expert knowledge to predict the impacts of the EIS alternatives on water quality. The co-lead agencies used standard points of compliance (fixed monitoring stations) that are located in the forebay and tailwater of each dam. These are the monitors we use to guide realtime operations and ensure compliance with water quality standards.
6506	47	Columbia River Keepers	Columbia River Keepers	19) Lines 1602-1603: Its good that the 303d listing for temperature is mentioned. However, a more detailed analysis of temperatures in Lake Roosevelt is needed.	Each alternative was evaluated to determine the change of temperature compared to No Action Alternative due to Lake Roosevelt at Grand Coulee's tailwater. This is the appropriate level of detail for an EIS. It is not clear what additional analysis the commenter is requesting for Lake Roosevelt, or the reason why additional analysis may be needed.
6506	48	Columbia River Keepers	Columbia River Keepers	20) Lines 2043-2048: As noted for other sections, compliance with the standard should be assessed by comparison to the free-flowing river scenario. Exceedance of criteria indicate impairment, which is important to describe, but comparison to natural conditions (absent the dams) is necessary to fully evaluate compliance with standards.	As stated in the Purpose and Need Statement in Section 1.2, the ongoing action that requires evaluation under NEPA is the long-term coordinated operation and management of the CRS projects for the multiple purposes. As mentioned in the Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulation, in the case where there is an ongoing management program or plan, the No Action Alternative would be "no change" from current management program or plan. The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 C.F.R. 1502.14) and provides a benchmark for comparing environmental effects of the other alternatives. The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change from 2016, which was the start of the EIS.
6506	49	Columbia River Keepers	Columbia River Keepers	21) Lines 2055-2061, Figures 3-12 and 3-13: a) The entire river should be assessed, not just the dam locations. Data could be pooled by reservoir reaches and by month to compare with cumulative distributions. b) Cumulative distributions are a powerful tool to assess temperature differences between dams and reservoirs. The percent of time and space that temperatures are at different levels has more relevance to salmon habitat.	The regional geographic scope of this EIS is broken down by reach, per resource for which effects are disclosed throughout the EIS and is much broader than just the dam locations. Please see Section 3.4.2 for the Water Quality Study Area Map for all of the river reaches studied. Water temperature, total dissolved gas and other physical, chemical and biological conditions comprise the parameters for water quality in the EIS.
6506	50	Columbia River Keepers	Columbia River Keepers	22) Lines 2205-2232: The lower Snake River is also listed on the 303d list for dissolved oxygen, pH and total phosphorus. The EIS should discuss these parameters in more detail. The effect of the dams on these parameters should be quantitatively evaluated. The lack of information is curious, given the information in Appendix C.	The EIS references the 303(d) list for the lower Snake River. However, there is no requirement for an EIS to quantitatively evaluate all parameters on the 303(d) list. The effects of the alternatives for water quality parameters other than temperature and total dissolved gas are describe qualitatively in Section 3.4 Water Quality under the headings titled Other Physical, Chemical, and Biological Processes.
6506	51	Columbia River Keepers	Columbia River Keepers	25) Lines 2268-2273: a) The entire river should be assessed, not just the dam locations. Data could be pooled by reservoir reaches and by month to compare with cumulative distributions. b) Cumulative distributions are a powerful tool to assess temperature differences between dams and reservoirs. The percent of time and space that temperatures are at different levels has more relevance to salmon habitat.	See response to Comment 6506-49.
6506	52	Columbia River Keepers	Columbia River Keepers	26) Lines 2698-2701: assertions are made about temperatures in Lake Roosevelt, but no citation or data are provided to support this narrative.	The document has been revised to add citations to address the comment.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6506	53	Columbia River Keepers	Columbia River Keepers	III. Appendix D Annex A 1) Lines 305-339, 1.3.4 Heat Flux and Model Parameterization Discussion: a) Although a table of parameters are provided, no reference is provided for the model framework. This makes it very difficult to interpret the discussion of the model development. b) The information provided suggests that the development of the 1-D free-flowing Snake River model was reasonable. However, the lack of a wind-sheltering coefficient appears to be significant. When comparing W2 results to HEC-RAS results to evaluate free-flowing conditions (MO3), this could introduce a bias into results. c) The discussion identifies the lack of a seasonal evaporation coefficient for the HEC-RAS model as a potential weakness of the model. The seasonal bias introduced by this short-coming is likely to occur both for the impounded model and the free-flowing model. d) If the 1-D model for the impounded system overpredicts temperature, its likely that the 1-D free-flowing model also overpredicts temperature. If so, when used as the basis for assessing impacts the 1-D model would tend to reduce the relative impact of the impounded system. e) The analysis should implement some methodology to address this potential bias. One approach would be to use sensitivity results to develop a range of values, and base the assessment probabilistically, such as through a Monte Carlo analysis or uncertainty analysis. Using this analysis, the potential for impacts on water quality should be viewed from a lens of conservative assumptions, such as a 95th percentile impact.	Model calibration reports were developed for all water quality models and are available by request. In addition, the commenter has not provided sufficient justification to support the assertion that the HEC-RAS model over-predicts summer temperatures in the Lower Snake and assertions in the paragraph are incorrect. The HEC-RAS model does have a way to adjust the wind-sheltering coefficients but uses different terminology: wind coefficients a, b, and c. HEC-RAS does change evaporation rates seasonally because evaporation rates depend on temperature and wind speed, similar to the approach used in CE-QUAL-W2. The co-lead agencies and EPA worked collaboratively to compare RBM-10 and the CRSO EIS water temperature models and concluded that the temperature predictions by both models are within a reasonable estimate of the uncertainty bounds. Differences between model estimates should be viewed as a reflection of the uncertainty in the predictive accuracy of the available tools. It should also be noted that both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. Additionally, as noted above, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059).
6506	54	Columbia River Keepers	Columbia River Keepers	2) Lines 408-409, Tables 1-7 and1-8: the results of the sensitivity to wind coefficients suggests that the limitations of HEC-RAS in modeling wind effects may have a strong influence on its accuracy.	The co-lead agencies disagree with this comment. Sensitivity is not a direct indication of model accuracy.
6506	55	Columbia River Keepers	Columbia River Keepers	3) Lines 467-482, Table 1-11, Figure 1-22: A comparison of the two models suggests some differences that affect the temperature results: a) The channel geometries and flow characteristics are different. HEC-RAS directly models flow, and they altered the geometry to 1934 conditions. RBM10 used 2010 geometry and they note that they did not alter geometry to the likely change to free-flowing conditions. This could affect temperatures from differences in water depth and width. b) RBM10 uses regional meteorology data from major airports. HECRAS uses local met data. This may be a significant source of error. The airport met stations are far from the river, and data from these locations may be different from local temperatures and wind velocities along the Snake River. This would be especially significant for wind, since that drives evaporation and is a major factor on large rivers and reservoirs.	Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). Please note that model calibration reports were developed for all water quality models and are available by request. In regards to HEC-RAS, this model does have a way to adjust the wind-sheltering coefficients but uses different terminology: wind coefficients a, b, and c. HEC-RAS does change evaporation rates seasonally because evaporation rates depend on temperature and wind speed, similar to the approach used in CE-QUAL-W2. As stated above, the co-lead agencies and USEPA worked collaboratively to compare RBM-10 and the CRSO EIS water temperature models and concluded that the temperature predictions by both models are within a reasonable estimate of the uncertainty bounds. Differences between model estimates should be viewed as a reflection of the uncertainty in the predictive accuracy of the available tools.
6506	56	Columbia River Keepers	Columbia River Keepers	4) Lines 536-567, 1.3.10.2 Temperature Comparison to No Action Alternative: These results are key to the analysis, but the presentation is confusing. a) Its not clear how NAA results were analyzed for comparison. Were these depth averaged, tailwater values, or some other value? b) Table 1-14 is not a useful way to present results. Data has been lumped into a single average and the two extremes are shown, along with pooled statistics. This reports very little information about temperatures in the two scenarios.	The No Action Alternative results are the CE-QUAL W2 water temperature output that represents fully mixed conditions at the dam locations, in the tailwater location of each CRS project. These results were compared to the cross section of the HEC-RAS MO3 model that is representative of the same tailwater locations (HEC-RAS results are always depth averaged). The data shown in Table 1-14 represents annual information and is not broken down into year type analysis. This is a sufficient way to compare the two models. The statistics shown are calculated using the same methodology that were used to analyze each EIS alternative.
6506	57	Columbia River Keepers	Columbia River Keepers	c) One of the challenges of comparing a reservoir to a free-flowing river is that the travel time changes and time lags can create difficulty comparisons. The analysis should evaluate whether changes in travel time are affecting results. d) Travel time can also affect fish exposure to temperatures, and this should be assessed and reported as well.	The co-lead agencies agree with the information contained in this comment. The impact of travel time cannot be evaluated independently from other hydraulic factors like depth. Changes in hydrology and flow have been captured in CSS and NMFS COMPASS fish modeling and analysis.
6506	58	Columbia River Keepers	Columbia River Keepers	e) The water quality standards are based on daily maximum values. If comparisons are made at a specific location (each dam) then the daily maximums should be compared.	The EIS analysis compares the daily maximum temperatures at each location, as the comment suggests.
6506	59	Columbia River Keepers	Columbia River Keepers	f) The entire river should be assessed, not just the dam locations. Data could be pooled by reservoir reaches and by month to compare with cumulative distributions. g) Cumulative distributions are a powerful tool to assess temperature differences between dams and reservoirs. The percent of time and space that temperatures are at different levels has more relevance to salmon habitat.	See response to Comment 6506-49.
6506	60	Columbia River Keepers	Columbia River Keepers	IV. DEIS Chapter 4 1) Lines 52-62: Its good to see the discussion of the RMJOC-II Part 1 findings. However, the footnote on page 4-2 is disturbing (The co-lead agencies expect this study [Part 2] to be published in spring 2020 after release of the draft EIS and will review the study to determine if any information presented in the draft EIS needs to be updated.) If the Part 2 study is close to being published, preliminary results should be available. With the huge investment in RMJOCII, and the quality and significance of the results, its essential that the Part 2 results be presented and included in the analysis. It is of vital importance to evaluate the relative impacts of climate change on the existing system of Snake River dams versus the MO3 option of dam breaching using the best available science, and both the RMJOC-II Part 1 and Part 2 results must be applied to the DEIS analysis to provide an analysis that is comprehensive and up-todate.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS.
6506	61	Columbia River Keepers	Columbia River Keepers	2) Lines 97-149, Sections 4.1.2.3 and 4.1.2.4: Loss of snowpack at all but the highest elevations in Canada, and the decline in summer and falls streamflow have enormous implications. More information on the RMJOC-II results in these areas should be provided. What are the magnitude of the changes expected? How does it affect the Alternatives? Does it suggest other alternatives, such as summer and fall drawdown, or partial breach with low level gates for split-season operation?	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). Streamflow changes at Grand Coulee that are quantitatively described in Section 4.1 are indicative of changes in Canada.
6506	62	Columbia River Keepers	Columbia River Keepers	3) Lines 214-246: The pattern shown of increased flows for future scenarios for the 5th percentile at Ice Harbor Dam should be explored further, especially when flows at Dworschak Dam decrease across the board. The graphs for this information found in RMJOC-II Part 1 report (pp 89-91) show different information from the graphs in the DEIS. The RMJOC-II Part 1 report shows flows shifting earlier and lower, while the DEIS shows flows about the same and with little temporal shift. The differences in this information should be evaluated and either corrected or explained.	The drainage area above Dworshak Dam is a small fraction of the drainage area above Ice Harbor. The hydroclimatology of flows at these two locations are likely to be different. The presentation of streamflow projections in the Draft EIS is different than in RMJOC-II Part 1, however, the underlying data are the same. The Draft EIS presented the range of two emissions scenarios and describes the range statistically. RMJOC-II Part 1 only showed the range of projections from the RCP 8.5 scenario. Additionally, the Draft EIS used more extreme flow percentiles, 5th and 95th, as opposed to 10th and 90th as used in RMJOC-II Part 1. The analysis referenced in RMJOC-II Part 1 presented daily data. The Draft EIS presents data at a monthly time interval. These differences in analyses contribute to some visual differences between the presentation of projections in the two reports, however, the overall patterns and magnitude of projected changes are consistent.
6506	63	Columbia River Keepers	Columbia River Keepers	4) Lines 351-355: Although the question posed is important, since it points to methods for adapting to climate change impacts, it is not the only question that should be evaluated. Another key question is: How will future climate change increase or decrease the projected impacts for each scenario? This would be consistent with the purpose of an Environmental Impacts Statement.	The approach for Section 4.2 was to1) identify potential impacts of climate change to the No Action Alternative and 2) evaluate how each alternative could influence those effects. Where possible, this includes describing how climate change could increase or decrease effects of the measures to resources.
6506	64	Columbia River Keepers	Columbia River Keepers	5) Lines 492-493: The statement that the effect of climate change on the MO3 flows will be similar to the NAA is unsupported and contrary to the significant change in river conditions absent the impoundments in the lower Snake River. The impact on the hydrology and hydraulics of other Alternatives will be fundamentally different from the impacts on a free-flowing Snake River in MO3. For the lower Snake Reservoirs flow changes affect reservoir elevations, power generation, navigation and fish flows. For MO3 the impacts would be felt on summer and fall flow volumes, velocities, and time of travel. The effect on the free flowing river will be different, and may be much smaller than the effect on an impounded river. The implications of climate change on flows in the lower Snake in MO3 should be discussed explicitly and in detail, especially focused on summer and fall flow volumes, velocities, and time of travel.	The changes to hydrology and hydraulics described in this section are limited to the effects of climate change and the resolution of the future projections. Section 4.1 reports changes in monthly flow volumes and timing. MO3 is not expected to alter flow volume and timing at this scale. More detailed analyses of the effects of a free-flowing river and hydraulics are provided in Chapter 3.
6506	65	Columbia River Keepers	Columbia River Keepers	6) Lines 539-541, Table 4-8: include a row for forest fire impacts, which would have significant impacts on erosion.	Wildfire and its effects on erosion is included in the "vegetation" row.
6506	66	Columbia River Keepers	Columbia River Keepers	7) Lines 607-610: This discussion should also make the point the free-flowing river would produce a cleansing of sediments in this reach that would be an environmental benefit to salmon habitat in this reach.	This effect is described in the context of spawning habitat in the anadromous and resident fish sections of Chapter 3. The Aquatic Invertebrate section of Chapter 3 describes the effect of a transition from silt and sand to more gravel and cobble.
6506	67	Columbia River Keepers	Columbia River Keepers	8) Lines 677-733: no discussion is provided of the impacts of climate change on Albeni Fall dam and the Pend Oreille River.	Climate change impacts can be found throughout Chapter 4. Climate change effects on Albeni Falls water quality are described in the first paragraph under Section 4.2.3.1.
6506	68	Columbia River Keepers	Columbia River Keepers	9) Lines 776-778: why only surface water temperature? Given the weak stratification and passage through multiple dams, it is likely to increase temperatures throughout the water column. This statement should be corrected.	In this context, surface water temperature refers to the distinction between surface and groundwater, not the lake surface as distinct from other points in a column of surface water.
6506	69	Columbia River Keepers	Columbia River Keepers	10) Lines 805-818: a) The discussion in this section is inadequate and misleading. The results from RMJOC-II Part 2 are needed here for a quantitative assessment that links those results to water quality modeling. b) This section provides no evidence to support the assumption that spring temperatures will be higher, including a quantitative assessment is provide to calculate the effects. A shallower, swifter river will have more cooling from surface radiation and bed conduction at night. Time of travel will also allow spring flows from snowmelt to move more quickly through the system with less time to warm. So the effect of climate change on spring temperatures may be less for MO3 than for the NAA c) This section provides no evidence of similar water temperatures in the summer. The pattern of temperatures are likely to be quite different. For the same reasons as noted for the spring, the overall effect of climate change on summer temperature may be less for MO3 than for the other alternatives. Wider daily swings in temperature are likely, but the heat mass of a reservoir may tend to promote a steady increase in temperature rather than relatively quick dissipation of temperatures at night for a free-flowing river. At mid-day temperatures may be higher, but at night they may be cooler. Since modeling of average temperatures shows a significant increase in reservoirs versus the free-flowing river, its quite possible that the change in average temperatures under climate change will be less in MO3 than in the other scenarios. d) Although this section provides no evidence of cooler water temperatures in the fall, this is the most likely outcome that available evidence suggests. The free-flowing river will respond more quickly to longer night and shorter days in the fall, as compared to the months required to dissipate the thermal mass of the reservoirs.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS. The climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). These analyses are documented in Section 4.2.3 for the MO Alternatives and Section 7.8.4 for the Preferred Alternative. Overall, the Preferred Alternative is expected to result in benefits to anadromous salmon and steelhead. The analysis in Section 7.8.4 recognizes that some of the benefits to fish from the Preferred Alternative could be offset by the effects of climate change. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges.
6506	70	Columbia River Keepers	Columbia River Keepers	11) Lines 1033-1034, Potential increased water temperature from MO3 in the spring could be further amplified by warming from climate change: Again, this statement is not supported by any evidence, and qualitative arguments suggest that spring temperature may be less affected by climate change under a free-flowing situation. A quantitative analysis with RMJOC-II Part 2 results is needed.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia Basin in still under development and was not available for us in this study. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS. The climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). These analyses are documented in Section 4.2.3 for the MO Alternatives and Section 7.8.4 for the Preferred Alternative. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges.
6506	71	Columbia River Keepers	Columbia River Keepers	12) Lines 1035-1038: this sentence is misleading. Although climate change may make habitat conditions worse in a freeflowing scenario, they are likely to be far worse in the impounded Alternatives, and the overall effect of climate change will be less on a free-flowing river than in an impounded river.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). Breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges.
6506	72	Columbia River Keepers	Columbia River Keepers	13) Lines 1972-1980: This section ignores the likely shift in recreational activities that could occur. Rafting of the Snake River above the Clearwater River is very popular, and there would likely be an economic boost from an expanded rafting industry. This section should explore the possibilities of this alternative recreation industry.	The Recreation Section 3.11.3.5 describes the potential social welfare and regional economic benefits to river-recreation, including recreational activities, such as drift boating, rafting, and kayaking, in the long-term under MO3.
6506	73	Columbia River Keepers	Columbia River Keepers	V. DEIS Chapter 5 1) A global comment for this section is the absence of discussion of the unique requirements of Section 303d of the Clean Water Act. A section should be added similar to Section 5.3 to discuss the compliance requirements for the CWA. In general this chapter need a more detailed an accurate of CWA requirements. The CWA does not allow mitigation standards must be met. Therefore, a discussion should be provided regarding how CRSO will meet the standards.	Sections 3.4 Water Quality and 7.7.3 Water Quality present the water quality analysis for all the alternatives. In addition, Chapter 8 describes compliance with all applicable laws, including the Clean Water Act. However, NEPA does not require an EIS to quantitatively evaluate all parameters on the 303d list.
6506	74	Columbia River Keepers	Columbia River Keepers	VI. DEIS Chapter 7 1) Lines 585-589, Table 7-1, Part 3: Environmental: use of Standards misused a) Water quality standards compliance discussed briefly under MO4, very briefly under a few, but not under others. All misstate or provide incomplete assessments of compliance with WQS (e.g. mitigate standards).	The co-lead agencies used the numeric criteria as short-hand to refer to the standard criteria that applies to the specific geography, time period, etc. specified in the water quality standard. This short-hand does not include antidegradation or natural condition. The co-lead agencies chose to use the daily maximum water temperature metric in the analysis because most state water quality standards for water temperature are based on this metric. The document was revised for clarity.
6506	75	Columbia River Keepers	Columbia River Keepers	2) Lines 1998-2015, p 7-80, Section 7.7.3.1: no mention of temperature impairment in Pend Oreille River. No change from NAA does not constitute compliance with clean water act.	The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 C.F.R. 1502.14), to provide a benchmark for comparing environmental effects of the other alternatives. The No Action Alternative considers what would happen if the Columbia River System continued to be operated, maintained, and configured with no change from 2016 at the start of the EIS. The EIS focused on the numeric water temperature criteria (20c) as a method to determine how a proposed action would effect river temperature as compared to the No Action Alternative. The effects of the dams are specifically analyzed in the EIS as required by the NEPA process. The temperature TMDL includes a full analysis of the impact of all anthropogenic and natural impacts on river temperatures, with the CRS dams being a part of that analysis.
6506	76	Columbia River Keepers	Columbia River Keepers	3) Lines 2072-2091, p 7-82, Section 7.7.3.2: misstatement and misinterpretation of standards for upper Columbia River	The co-lead agencies used the numeric criteria as short-hand to refer to the standard criteria that applies to the specific geography, time period, etc. specified in the water quality standard. This short-hand does not include antidegradation or natural condition. The co-lead agencies chose to use the daily maximum water temperature metric in the analysis because most state water quality standards for water temperature are based on this metric. The document was revised for clarity.
6506	77	Columbia River Keepers	Columbia River Keepers	4) Lines 2134-2158, p 7-84, Section 7.7.3.3: misstatement and misinterpretation of standards for the lower Snake River	The co-lead agencies used the numeric criteria as short-hand to refer to the standard criteria that applies to the specific geography, time period, etc. specified in the water quality standard. This short-hand does not include antidegradation or natural condition. The co-lead agencies chose to use the daily maximum water temperature metric in the analysis because most state water quality standards for water temperature are based on this metric. The document was revised for clarity.
6506	78	Columbia River Keepers	Columbia River Keepers	5) Lines 2195-2215, p 7-85 & 86, Section 7.7.3.4: misstatement and misinterpretation of standards for lower Columbia River.	The co-lead agencies used the numeric criteria as short-hand to refer to the standard criteria that applies to the specific geography, time period, etc. specified in the water quality standard. This short-hand does not include antidegradation or natural condition. The co-lead agencies chose to use the daily maximum water temperature metric in the analysis because most state water quality standards for water temperature are based on this metric. The document was revised for clarity.
6506	79	Columbia River Keepers	Columbia River Keepers	6) Lines 1997-2268, Section 7.7.3, general: The Columbia and Snake Rivers are listed as impaired under C=CWA 303d. This is not mentioned. Saying it is no worse under PA than under NAA, is saying that the PA does nothing to improve temperature impairments.	The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality NEPA regulations (40 C.F.R. 1502.14), and provides a benchmark for comparing environmental effects of the other alternatives. The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change from 2016, which was the start of the EIS. The EIS focused on the numeric water temperature criteria (20c) as a method to determine how a proposed action would impact river temperature as compared to the No Action Alternative. The effects of the dams are specifically analyzed in the EIS as required by the NEPA process. The temperature TMDL being developed by the USEPA, as per their authority under the CWA, will include a full analysis of the impact of all anthropogenic and natural impacts on river temperatures, with the CRS dams being a part of that analysis. The TMDL will determine what temperature reductions are needed to meet state water quality standards across the basin. The 303(d) listings of the Columbia and Snake rivers is mentioned in Section 3.4, Affected Environment, which is relied upon for the analysis of the Preferred Alternative in Chapter 7. The 303(d) listing are also discussed in Appendix D.
6506	80	Columbia River Keepers	Columbia River Keepers	7) Lines 2269-3158, Section 7.7.4, general: There is very little discussion about temperature effects. The DEIS makes little mention of current research on temperature impacts on migration and the use of cold water refuges, even though it is mentioned in Appendix D.	Studies related to water temperature and its effects on fish are referenced throughout Chapter 7 (which builds on the analysis through the previous chapters) and Technical Appendices D and E. As mentioned in the comment, EPA's Cold Water Refugia report is referenced in the EIS document, along with a list of other water quality actions.
6514	1	fraxinus@reachone.com	N/A	Scientific basis of modeling 1. CE-QUAL-W2 (W2) is an appropriate and robust model for modeling reservoirs. Unfortunately, there are significant gaps in information regarding how the model was developed for the DEIS. a. I have been unable to find any information or citations to the calibration of the model or other model quality assessment analyses. The DEIS provides one calibration statistic, but the method of calculation is not provided. Typically, model quality assessment is demonstrated with a detailed analysis of calibration metrics and other methods such as validation, uncertainty analysis, and sensitivity analysis. b. It is unclear how model output was structured, or how results were averaged or analyzed in other ways. c. CE-QUAL-W2 can be used for free-flowing rivers. It is unclear how much effort went into testing W2 for this application before it was abandoned in favor of HEC-RAS.	Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). Please note that model calibration reports were developed for all water quality models and are available by request. In regards to HEC-RAS, this model does have a way to adjust the wind-sheltering coefficients but uses different terminology: wind coefficients a, b, and c. HEC-RAS does change evaporation rates seasonally because evaporation rates depend on temperature and wind speed, similar to the approach used in CE-QUAL-W2.
6514	2	fraxinus@reachone.com	N/A	2. The modeling of the Snake River with HEC-RAS for the MOS3 free-flowing scenario is described in Annex A of Appendix D. This model appears to have significant flaws for modeling the Snake River. I have several concerns about the information provided and appropriateness of the analysis. a. The DEIS provides inadequate information about the framework or calibration of the HEC-RAS model. Again the DEIS should provide more detailed information about parameter selection and model quality metrics.	Model calibration reports were developed for all water quality models and are available by request. Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). The co-lead agencies and USEPA concluded that the temperature predictions by both models are within a reasonable estimate of the uncertainty bounds. Differences between model estimates should be viewed as a reflection of the uncertainty in the predictive accuracy of the available tools. In addition, the EIS and the supporting models underwent a third party, neutral Independent External Peer Review by well respected scientists who concluded that the analysis was appropriate.
6514	3	fraxinus@reachone.com	N/A	b. The report points out several problems with the use of HEC-RAS for the Snake River. They admit that the model calibrates poorly and point to several causes. First, unlike W2, HEC-RAS has no wind sheltering coefficient. Wind-driven evaporation can be a major factor in accurately describing temperature regimes in reservoirs and wide rivers. HEC-RAS has several other wind coefficients, and the sensitivity analysis they provide indicates that this is a critical parameter. Yet it is unclear how the coefficients are used in calibration and the difference between these coefficients and a wind-sheltering coefficient. Second, HEC-RAS has no method to adjust evaporation seasonally. As a result, water temperatures in the model results are too high in summer and too low in winter. The report states that the HEC-RAS model is believed to corroborate the HEC-RAS heat balance routines and the parameter set for a one-dimensional representation of a dam breach bathymetry. However, the problems they identify earlier in the discussion	Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). Please note that model calibration reports were developed for all water quality models and are available by request. In regards to HEC-RAS, this model does have a way to adjust the wind-sheltering coefficients but uses different terminology: wind coefficients a, b, and c. HEC-RAS does change evaporation rates seasonally because evaporation rates depend on temperature and wind speed, similar to the approach used in CE-QUAL-W2.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				contradicts this statement. If the problems with evaporation and wind sheltering are seen with the reservoirs, they will likely affect the free-flowing too. The free-flowing river is still wide, and will still have seasonal variation. They are hopeful that uncertainty swings their way, but the evidence they supply does not support their statement.	
6514	4	fraxinus@reachone.com	N/A	c. To summarize the problems with model uncertainty: 1) The HEC-RAS undammed river model calibrates poorly, so the results are uncertain. The evidence provided suggests that it might be overpredicting water temperatares in summer. 2) The W2 model also has inherent uncertainty, and how results are averaged for comparison to the HEC-RAS model adds to uncertainty. 3) The uncertainty of both models is compounded when they are compared to each other. If HEC-RAS is overpredicting temperature, then the impacts of the impoundments on water temperature may be worse than the DEIS estimates. For the protection of the environment, this uncertainty should be evaluated, a range of impacts estimated, and conclusions drawn from the more severe estimates of impacts.	The reference to the HEC-RAS overprediction of water temperatures (in Annex A) was part of an evaluation of the use of a one-dimensional model under current conditions and is not related to the accuracy of the MO3 water temperature predictions. There is no evidence that HEC-RAS overpredicts water temperatures for the MO3 Alternative. Additionally, both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059).
6514	5	fraxinus@reachone.com	N/A	Use of the model to assess Water Quality Standards (WQS) 3. The DEIS is inconsistent in identifying where Section 303d impairments exist and where draft TMDLs have or will be developed. These facts are noted in some sections but not in others. This creates confusion and seems to misstate the relationship of the DEIS to the Clean Water Act and State water quality programs.	The EIS does not include an exhaustive list of all 303d or draft TMDLs that exist in the basin, but rather discusses those impairments applicable to the water quality discussion. The importance of the Clean Water Act and comparison to State water quality standards is discussed throughout the document and is by no means ignored.
6514	6	fraxinus@reachone.com	N/A	4. The DEIS misstates and misuses the Water Quality Standards (WAC 173-201A in Washington). a. Some of this confusion is indicated by the misuse of the term standards when actually referring to the criteria in the standards. The Water Quality Standards are the entire regulation, with a variety of elements such as criteria, designated uses, anti-degradation, natural conditions.	The co-lead agencies used the numeric criteria as short-hand to refer to the standard criteria that applies to the specific geography, time period, etc. specified in the water quality standard. This short-hand does not include antidegradation or natural condition. The co-lead agencies chose to use the daily maximum water temperature metric in the analysis because most state water quality standards for water temperature are based on this metric. The document was revised for clarity.
6514	7	fraxinus@reachone.com	N/A	b. Compliance with the criteria is only on part of compliance with the WQS. For rivers like the Columbia and Snake, the natural conditions provisions often apply. Natural conditions is defined in the standards as absent human-caused pollution, and in the case of this DEIS is represented by the free-flowing river modeling scenario. For temperature, either the criteria should be met, or if natural conditions are within 0.3 degrees C of the criterion or higher, thermal load cannot be added to the river that increases temperatures by more than 0.3 degrees C. 5. The effects of the dams are only illustrated at the dams themselves. The DEIS should show an analysis that evaluates all parts of the river and identifies the locations that have the greatest temperature impairment.	The scope of the EIS is described in Section 1.3 of the EIS. The effects of the dams are described in the EIS as part of the Affected Environment sections in accordance with NEPA regulations. The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 C.F.R. 1502.14) and is used for comparing the environmental effects of the other alternatives. The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change from 2016, which was the start of the EIS. A comprehensive analysis of the river temperature will be completed by USEPA's temperature TMDL analysis. The temperature TMDL being developed by the USEPA, as per their authority under the CWA, will be conducting a full analysis of the impact of both anthropogenic and natural impacts on river temperatures, which will include the CRS dams. The TMDL will determine what temperature reductions are needed to meet state water quality standards by all sources of heat in the river. For more information on the TMDL for temperature for the Columbia and lower Snake rivers can be found at https://www.epa.gov/columbiariver/tmdl-temperature-columbia-and-lower-snake-rivers
6514	8	fraxinus@reachone.com	N/A	6. Just as the DEIS should identify actions that need to be taken to restore endangered species, actions should also be identified to comply with water quality standards. The analysis of water quality that compares the No Action Alternative (NAA) to other alternatives is not a valid assessment of compliance with the standards. At best this approach only shows if alternatives allow greater or lesser impairment, not the level of compliance with the standards. 7. This shortcoming is particularly evident in the Impact Framework and Decision Criteria. The narrative and illustrations provide little explanation of how criteria were developed, and overall appear to be arbitrarily chosen. They do not align with water quality standards, and no information is provided to demonstrate that they are significant from the perspective of salmon biology.	The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 C.F.R. 1502.14) and is used for comparing the environmental effects of the other alternatives. The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change from 2016, which was the start of the EIS. For water temperature analysis, the co-lead agencies chose to use the daily maximum water temperature metric because most state water quality standards for water temperature are based on this metric. In addition, this information was used to summarize results into a negligible, minor, moderate or major category, based on the number of days that results are above or within the water quality standard, as compared to the No Action Alternative. This is described in the Impact Framework and Decision Criteria in Section 3.4.3.2 and Appendix D, Section 2.6.
6514	9	fraxinus@reachone.com	N/A	8. Comparing temperature and DO levels in a free-running river to those in a reservoir is challenging. Robust methods have been developed to compare conditions in the two water bodies using cumulative frequency distributions. Examples can be found in Willamette River TMDLs and the draft Pend Oreille River TMDL. These methods avoid errors in comparing scenarios with different travel times, while also pooling data in a way that is relevant to salmon habitat.	The co-lead agencies chose to use a process-based model to predict impacts to dissolved oxygen rather than empirical models that may have little relevance to the system. When applied correctly, process or physically based models better capture impacts from changing conditions than empirical models that are developed based on existing conditions.
6514	10	fraxinus@reachone.com	N/A	9. The comparison of the W2 modeling in the NAA to the HEC-RAS model in MO3 may introduce biases that downplay the differences. Annex A notes that HEC-RAS tends to over predict temperature. At the same time, its unclear how W2 analyzes temperature for comparison. If the W2 analysis provides water temperature results that vary in accuracy, and these are then compared to HEC-RAS results that overpredict temperatures, the result would be an inaccurately low difference between the two scenarios. a. Running the HEC-RAS for the reservoirs and comparing results with W2 for the reservoirs should suggest ways to account quantitatively for these differences. Also, statistical tools like cumulative distributions might be useful. Characterization of the rivers with model results	The reference to the HEC-RAS overprediction of water temperatures (in Annex A) was part of an evaluation of the use of a one-dimensional model under current conditions and is not related to the accuracy of the MO3 water temperature predictions. There is no evidence that HEC-RAS overpredicts water temperatures for the MO3 Alternative. Additionally, both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059).
6514	11	fraxinus@reachone.com	N/A	10. The DEIS makes broad statements about water quality in the study area, but rarely do they provide quantitative evidence or citations to back the statements. This falls short of the level of scientific communication that one would expect from a document of this significance and technical detail.	The level of detail provided in the EIS is sufficient to adequately describe the effects of the alternatives on water quality in comparison to the No Action Alternative, as required in the NEPA regulations. In addition to the information contained in Section 3.4 and Section 7.7.3 pertaining to water quality, additional information can be found in Appendix D.
6514	12	fraxinus@reachone.com	N/A	11. Evidence or citations should be provided to show that data and modeling information used in the DEIS met data quality standards. Quality assurance and quality control (QAQC) plans are typically required of federal studies (they certainly are for State studies). The absence of QAQC information is at best poor science communication, and may also represent a violation of federal laws for data quality. Evaluation of Climate Change	Model calibration reports were developed for all water quality models and are available by request. Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). The co-lead agencies and USEPA concluded that the temperature predictions by both models are within a reasonable estimate of the uncertainty bounds. Differences between model estimates should be viewed as a reflection of the uncertainty in the predictive accuracy of the available tools. Typically, QAQC plans are related to data collection. The co-lead agencies, however, did develop a QAPP (Quality Assurance Project Plan) that is related to the models used in the EIS. In addition, the EIS underwent a third party, neutral Independent External Peer Review.
6514	13	fraxinus@reachone.com	N/A	12. Its good to see the discussion of the RMJOC-II Part 1 findings. However, the footnote on page 4-2 is disturbing (The co-lead agencies expect this study [Part 2] to be published in spring 2020 after release of the draft EIS and will review the study to determine if any information presented in the draft EIS needs to be updated.) The Part 2 study provides projections for flows in the current system for future climate change scenarios. If the Part 2 study is close to being published, preliminary results should be available. With the huge investment in RMJOC-II, and the quality and significance of the results, its essential that the Part 2 results be included in the DEIS. It is of vital importance to evaluate the relative impacts of climate change on the existing system of Snake River dams versus the MO3 option of dam breaching using the best available science. Both the RMJOC-II Part 1 and Part 2 results must be applied to the water quality modeling to evaluate future water temperatures for all Alternatives.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS.
6514	14	fraxinus@reachone.com	N/A	13. Results presented in the DEIS from the RMJOC-II Part 1 report are not consistent with the information found in the Part 1 report. Either the DEIS is in error, or different results have been selected for the DEIS than were published in the Part 1 report. Without explanation, this opens the DEIS to the appearance of cherry-picking data to support a preferred message.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS.
6514	15	fraxinus@reachone.com	N/A	14. The discussion in Section 4.2.3.3 regarding climate impacts on the MO3 alternative (Snake River dam breach) is inadequate and misleading. Little evidence is provided to support their assertion about climate impacts on the free-flowing river, and the discussion points to the effect of climate change on the free-flowing river while saying little about the relative impact of climate change on MO3 versus the other alternatives. This is all the more reason that the RMJOC-II results from both Part 1 and 2 need to be applied to water quality models to quantify impacts of all alternatives in a warming future. Comparison of HEC-RAS to RBM10 free-flowing model	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS.
6514	16	fraxinus@reachone.com	N/A	15. The comparison of these two models in Annex A suggests some differences that affect the temperature results: a. The channel geometries and flow characteristics are different. HEC-RAS directly models flow, and they altered the geometry to 1934 conditions. RBM10 used 2010 geometry and they note that they did not alter geometry to the likely change to free-flowing conditions. This could affect temperatures from differences in water depth and width. b. RBM10 uses regional meteorology data from major airports. HECRAS uses local met data. This may be a significant source of error. The airport met stations are far from the river, and data from these locations may be different from local temperatures and wind velocities along the Snake River. This would be especially significant for wind, since that drives evaporation and is a major factor on large rivers and reservoirs.	Thank you for your comment.
6514	17	fraxinus@reachone.com	N/A	I. Global 1) Throughout the EIS and appendices, the term standards is misused. The standards are the entire state regulation. Often the text refers to the criterion, but calls it the standard. Please revise the document to make sure that standard only applies to references to the entire rule, while criterion refers to the specific numeric target.	The co-lead agencies used the numeric criteria as short-hand to refer to the standard criteria that applies to the specific geography, time period, etc. specified in the water quality standard. This short-hand does not include antidegradation or natural condition. The co-lead agencies chose to use the daily maximum water temperature metric in the analysis because most state water quality standards for water temperature are based on this metric. The document was revised for clarity.
6514	18	fraxinus@reachone.com	N/A	II. Appendix D - Body 1) Lines 1085-1086: Numerical modeling is needed to quantify temperature impacts from the dams addressed in this DEIS. According to a footnote in Chapter 4, a Part 2 study is close to being published. If so, preliminary results should be available. With the huge investment in RMJOC-II, and the quality and significance of the results, its essential that the Part 2 results be used to develop water temperature models of the Alternatives. The RMJOC-II Part 1 results are already available and could be applied to the modeling described in Annex A. However, for comparison, all	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia Basin in still under development and was not available for this EIS. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				of the Alternatives should be modeled for future impacts under climate change scenarios. It is of vital importance to evaluate the relative impacts of climate change on the existing system of Snake River dams versus the MO3 option of dam breaching using the best available science. Both the RMJOC-II Part 1 and Part 2 results must be applied to the DEIS analysis to provide an analysis that is comprehensive and up-to-date.	change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS.
6514	19	fraxinus@reachone.com	N/A	2) Lines 1136: list the Tribes with water quality standards in the Study Area (Spokane, Colville, Nez Perce	Tribal Water Quality Standards are noted throughout the EIS where applicable.
6514	20	fraxinus@reachone.com	N/A	3) Lines 1138-1194: although the models used for this analysis (CE-QUAL-W2 and HEC-RAS) are described in a general way, no information or references are provided to describe the model development. This is a serious flaw information on the parameterization of the model and model quality assessment (calibration, validation, uncertainty or sensitivity analysis) is inadequate. As a result, there is no way to assess the quality and credibility of the modeling. This is both inconsistent with scientific modeling principles and likely also not in compliance with state and federal laws for the use of credible data in environmental decision-making.	Model calibration reports were developed for all water quality models and are available by request. Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). The co-lead agencies and USEPA concluded that the temperature predictions by both models are within a reasonable estimate of the uncertainty bounds. Differences between model estimates should be viewed as a reflection of the uncertainty in the predictive accuracy of the available tools. Typically, QAQC plans are related to data collection. The co-lead agencies, however, did develop a QAPP (Quality Assurance Project Plan) that is related to the models used in the EIS. In addition, the EIS underwent a third party, neutral Independent External Peer Review.
6514	21	fraxinus@reachone.com	N/A	4) Lines 1170, 1174, 1182: temperature metrics air or water temperature? Please clarify.	As described in the sentence preceding these lines, a five-year period (20112015) that represent a wide range of environmental response to hydrology (wet, dry, average) and weather conditions (hot, cold, average) were selected to model each EIS alternative against. Temperature metrics in this Section refer to the weather conditions (hot, cold, average air temperatures). This has been added to the text for clarity.
6514	22	fraxinus@reachone.com	N/A	5) Lines 1177, 1180: water temperature response was near average unclear, response to what? How analyzed model or statistical?	Water temperature response was near average as compared to the period of record data that was used to select the five-year data set to run through the water quality model. The response referred to was to the combination of air temperature and flow conditions. Additional information can be found in the model calibration report, which is available upon request.
6514	23	fraxinus@reachone.com	N/A	6) Lines 1199-1201: Using CE-QUAL-W2 for free-flowing rivers is possible but difficult. But it would be better to use the same model for comparison of undammed to dammed.	The co-lead agencies evaluated the possibility of using CE-QUAL W2 for MO3, but concluded that HEC-RAS was an appropriate approach for water temperature modeling under a dam breach scenario and free-flowing river system. W2 captured the thermal dynamics of the reservoirs quite well under most CRSO alternatives but became quite unstable when applied to the lower Snake River as a riverine reach; and, since well-mixed thermal conditions would be expected under a dam breach scenario, using a 2-dimensional model like W2 was not as necessary.
6514	24	fraxinus@reachone.com	N/A	7) Lines 1213 (Table 2-1): a) Hourly time step and daily maximum is more appropriate for assessing compliance with the WQS. b) Was channel geometry changed between free-flowing and dam scenarios? This introduces an additional source of uncertainty that should be checked. Differences in depth and velocity could affect temperature predictions.	The co-lead agencies used hourly timesteps to evaluate daily maximum water temperature for comparison to water quality standards. For MO3, the co-lead agencies used pre-dam channel bathymetry to predict water temperatures under a dam breach scenarios. The quantification of uncertainty due to bathymetry is beyond the scope of this EIS.
6514	25	fraxinus@reachone.com	N/A	8) Lines 1287: Why were these temperature change values chosen?	The co-lead agencies offer one way of organizing the EIS water temperature and TDG results, but other techniques could be used. The methodology the co-lead agencies chose was used to assign results into negligible, minor, moderate or major categories based on the absolute change in water temperature, number of days that water temperatures exceeded state water quality standard and seasonality of change (based on whether anadromous fish are present or not). This methodology was reviewed by the EIS Fish Team and NMFS. In general, metrics were chosen based on: (1) absolute change in water temperature that the team considered to be measurable; (2) change in the days that water temperature standards were exceeded that was determined to be more related to the EIS Alternative than seasonal/climatic variability. Hourly water temperature results for each 5-year simulation are also provided in Appendix D.
6514	26	fraxinus@reachone.com	N/A	9) Lines 1288-1290: changes in days of non-compliance, pooled by month or season, is a reasonable metric. However the seasons chosen are not described.	The seasons are defined as winter = December - February; spring = March - May; summer = June - August; and fall = September - November. This information has been added to Appendix D.
6514	27	fraxinus@reachone.com	N/A	10) Lines 1306 (Figure 2-3): a) The Impact Framework and Decision Criteria seem arbitrary. b) The criteria for negligible, minor or moderate is unclear and seems arbitrary. c) The key metric for the assessing the temperatures should be applying by the State water quality standards: the number of days and magnitude of increases over the criterion when natural (free-flowing) is below the criterion, or greater than 0.3 over natural when natural is above or within 0.3 of the criterion.	The methodology used described water quality effects as negligible, minor, moderate or major categories as is typical in NEPA documents. These determinations were made based on the absolute change in water temperature, number of days that water temperatures exceeded state water quality standard and seasonality of change (based on whether anadromous fish are present or not). In general, metrics were chosen based on: (1) absolute change in water temperature that the team considered to be measurable; (2) change in the days that water temperature standards were exceeded that was determined to be more related to the EIS alternative than seasonal/climatic variability. Hourly water temperature results for each five-year simulation are also provided in Appendix D.
6514	28	fraxinus@reachone.com	N/A	11) Lines 1293-1301: TDG decision criteria seem arbitrary and inappropriate. TDG hurts fish on a short time scale, not as a five year average. Change in the number of days with values over 115, 120, and 125 would be more appropriate.	Change in the number of days that TDG results exceed specific thresholds (110%, 115%, 120%, etc.) can be found in Appendix D for each alternative. The co-lead agencies' summary metrics are documented to provide a single impact level summary for the system. The methodology selected by the co-lead agencies was used to allow the results to be described as negligible, minor, moderate or major categories based on the absolute change in TDG per season and per year and then averaged for all five years. Hourly TDG results for each five-year simulation are also provided in Appendix D.
6514	29	fraxinus@reachone.com	N/A	12) Lines 1307-1331: Discussion of uncertainty is fairly general, but descriptions of issues seem appropriate.	Thank you for your comment.
6514	30	fraxinus@reachone.com	N/A	13) Lines 1335-1338: DO and pH can have a significant effect on metals in sediment. Whether this is minor is debatable, and depends on the ranges of those values occurring in the reservoirs.	Yes, pH and DO can effect metals in sediment; such processes can be very complex and difficult to predict.
6514	31	fraxinus@reachone.com	N/A	14) Lines 1418-1421: There is also a draft TMDL for temperature in the Pend Oreille River, which is affected by Albeni Falls Dam operations.	This list included in the text is not intended to be a full, complete list of all TMDLs. The co-lead agencies mention the Albeni Falls water temperature TMDL in Appendix D, Section 3.1.1.2.
6514	32	fraxinus@reachone.com	N/A	15) Lines 1440-1444: there are court decisions related contributing or increasing a contribution to 303d impairments. This paragraph is not an accurate description of the situation (problems would continue until the sources of impairment are addressed.) The dams have been identified as sources of impairment, and the EIS should address whether the alternatives increase or decrease impairment.	The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 C.F.R. 1502.14) and is used for comparing the environmental effects of the other alternatives. The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change from 2016, which was the start of the EIS. The EIS focused on the numeric water temperature criteria (20c) as a method to determine how the alternatives would impact river temperature when compared to the No Action Alternative. The effects of the dams are specifically described in the Affected Environment sections of the EIS as required by NEPA. The temperature TMDL that was recently issued by the USEPA, as per their authority under the CWA, will include a full analysis of the impact of all anthropogenic and natural impacts on river temperatures, with the CRS dams being a part of that analysis. The TMDL will determine what temperature reductions are needed to meet state water quality standards across the basin. For more information on the TMDL for temperature for the Columbia and lower Snake rivers can be found at https://www.epa.gov/columbiariver/tmdl-temperature-columbia-and-lower-snake-rivers.
6514	33	fraxinus@reachone.com	N/A	16) Lines 1586-1598: The discussion of stratification (and other discussions that follow) should provide citations and quantitative metrics to back the descriptions provided.	The document has been revised add citations to address the comment.
6514	34	fraxinus@reachone.com	N/A	17) Lines 1599-1603: The changes in temperature from tailwater to tailwater are not a useful or valid assessment of temperature impacts. Temperatures should be compared to a free-flowing river model to quantify the impacts of the NAA.	As stated in the Purpose and Need Statement in Section 1.2, the ongoing action that requires evaluation under NEPA is the long-term coordinated operation and management of the CRS projects for the multiple purposes. As mentioned in the Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulation, in the case where there is an ongoing management program or plan, the No Action Alternative would be "no change" from current management program or plan. The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 C.F.R. 1502.14) and provides a benchmark for comparing environmental effects of the other alternatives. The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change from 2016, which was the start of the EIS. The co-lead agencies used the standard points of compliance (fixed monitoring stations) that are located in the forebay and tailwater of each dam for the analysis, as these are the monitors used to guide real-time operations and ensure compliance with water quality standards.
6514	35	fraxinus@reachone.com	N/A	18) Lines 1599-1625: a) The entire river should be assessed, including the reservoirs, not just the dam locations. b) Data could be pooled by reservoir reaches and by month to compare with cumulative distributions.	The scope of this EIS focused on the operation of the 14 Federal dams in the CRS as described in Section 1.3 Scope of the Project of the EIS. That said, the system water quality model's extent includes the entire mainstem river, from the international boundary above Grand Coulee Dam to just downstream of Bonneville Dam at Warrendale, Oregon. The co-lead agencies chose to pull model output from the fixed monitoring stations, located upstream and downstream of each dam, since these are the typical locations where data is utilized when making real-time water management decisions and ensuring compliance with water quality standard.
6514	36	fraxinus@reachone.com	N/A	19) Lines 1602-1603: Its good that the 303d listing for temperature is mentioned. However, a more detailed analysis of temperatures in Lake Roosevelt is needed.	Each MO evaluated the change of temperature from No Action Alternative due to Lake Roosevelt at Grand Coulee's tailwater. This is the appropriate level of detail for an EIS. It is not clear what additional analysis the commenter is requesting for Lake Roosevelt, or the reason why additional analysis may be needed.
6514	37	fraxinus@reachone.com	N/A	20) Lines 2043-2048: As noted for other sections, compliance with the standard should be assessed by comparison to the free-flowing river scenario. Exceedance of criteria indicate impairment, which is important to describe, but comparison to natural conditions (absent the dams) is necessary to fully evaluate compliance with standards.	As stated in the Purpose and Need in Section 1.2, the ongoing action that requires evaluation under NEPA is the long-term coordinated operation and management of the CRS projects for the multiple purposes. As mentioned in the Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulation, in the case where there is an ongoing management program or plan, the No Action Alternative would be "no change" from current management program or plan. The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 C.F.R. 1502.14) and provides a benchmark for comparing environmental effects of the other alternatives. The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change from 2016, which was the start of the EIS.
6514	38	fraxinus@reachone.com	N/A	21) Lines 2055-2061, Figures 3-12 and 3-13: a) The entire river should be assessed, not just the dam locations. Data could be pooled by reservoir reaches and by month to compare with cumulative distributions. b) Cumulative distributions are a powerful tool to assess temperature differences between dams and reservoirs. The percent of time and space that temperatures are at different levels has more relevance to salmon habitat.	The scope of this EIS focused on the operation of the 14 Federal dams in the CRS as described in Section 1.3 Scope of the Project of the EIS. That said, the system water quality model's extent includes the entire mainstem river, from the international boundary above Grand Coulee Dam to just downstream of Bonneville Dam at Warrendale, Oregon. The co-lead agencies chose to pull model output from the fixed monitoring stations, located upstream and downstream of each dam, since these are the typical locations where data is utilized when making real-time water management decisions and ensuring compliance with water quality standards.
6514	39	fraxinus@reachone.com	N/A	22) Lines 2205-2232: The lower Snake River is also listed on the 303d list for dissolved oxygen, pH and total phosphorus. The EIS should discuss these parameters in more detail. The effect of the dams on these parameters should be quantitatively evaluated. The lack of information is curious, given the information in Appendix C.	The EIS references the 303(d) list for the lower Snake River. However, there is no requirement for an EIS to quantitatively evaluate all parameters on the 303(d) list. The effects of the alternatives for water quality parameters other than temperature and total dissolved gas are describe qualitatively in Section 3.4 Water Quality under the headings titled Other Physical, Chemical, and Biological Processes.
6514	40	fraxinus@reachone.com	N/A	23) Lines 2243-2245: Good to see the 303d listing mentioned	Thank you for your comment.
6514	41	fraxinus@reachone.com	N/A	24) Lines 2245-2258: good to see cold water refuges discussed.	Thank you for your comment.
6514	42	fraxinus@reachone.com	N/A	25) Lines 2268-2273: a) The entire river should be assessed, not just the dam locations. Data could be pooled by reservoir reaches and by month to compare with cumulative distributions. b) Cumulative distributions are a powerful tool to assess temperature differences between dams and reservoirs. The percent of time and space that temperatures are at different levels has more relevance to salmon habitat.	The scope of this EIS focused on the operation of the 14 Federal dams in the CRS as described in Section 1.3 Scope of the Project of the EIS. That said, the system water quality model's extent includes the entire mainstem river, from the international boundary above Grand Coulee Dam to just downstream of Bonneville Dam at Warrendale, Oregon. The co-lead agencies chose to pull model output from the fixed monitoring stations, located upstream and downstream of each dam, since these are the typical locations where data is utilized when making real-time water management decisions and ensuring compliance with water quality standard.
6514	43	fraxinus@reachone.com	N/A	26) Lines 2698-2701: assertions are made about temperatures in Lake Roosevelt, but no citation or data are provided to support this narrative.	The document was revised to add citations to address the comment.
6514	44	fraxinus@reachone.com	N/A	III. Appendix D Annex A 1) Lines 305-339, 1.3.4 Heat Flux and Model Parameterization Discussion: a) Although a table of parameters are provided, no reference is provided for the model framework. This makes it very difficult to interpret the discussion of the model development. b) The information provided suggests that the development of the 1-D free-flowing Snake River model was reasonable. However, the lack of a wind-sheltering coefficient appears to be significant. When comparing W2 results to HEC-RAS results to evaluate free-flowing conditions (MO3), this could introduce a bias into results. c) The discussion identifies the lack of a seasonal evaporation coefficient for the HEC-RAS model as a potential weakness of the model. The seasonal bias intrwatoduced by this short-coming is likely to occur both for the impounded model and the free-flowing model. d) If the 1-D model for	Model calibration reports were developed for all water quality models and are available by request. In addition, the commenter has not provided sufficient justification to support the assertion that the HEC-RAS model over-predicts summer temperatures in the Lower Snake and assertions in the paragraph are incorrect. HEC-RAS model does have a way to adjust the wind-sheltering coefficients but uses different terminology: wind coefficients a, b, and c. HEC-RAS does change evaporation rates seasonally because evaporation rates depend on temperature and wind speed, similar to the approach used in CE-QUAL-W2. The co-lead agencies and EPA worked collaboratively to compare RBM-10 and the CRSO EIS water temperature models and concluded that the temperature predictions by both models are within a reasonable estimate of the uncertainty bounds. Differences between model estimates should be viewed as a reflection of the uncertainty in the predictive accuracy of the available tools.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the impounded system overpredicts temperature, its likely that the 1-D free-flowing model also overpredicts temperature. If so, when used as the basis for assessing impacts the 1-D model would tend to reduce the relative impact of the impounded system. e) The analysis should implement some methodology to address this potential bias. One approach would be to use sensitivity results to develop a range of values, and base the assessment probabilistically, such as through a Monte Carlo analysis or uncertainty analysis. Using this analysis, the potential for impacts on water quality should be viewed from a lens of conservative assumptions, such as a 95th percentile impact.	It should also be noted that both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, as noted above, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059).
6514	45	fraxinus@reachone.com	N/A	2) Lines 408-409, Tables 1-7 and1-8: the results of the sensitivity to wind coefficients suggests that the limitations of HEC-RAS in modeling wind effects may have a strong influence on its accuracy.	The co-lead agencies disagree with this comment. Sensitivity is not a direct indication of model accuracy.
6514	46	fraxinus@reachone.com	N/A	3) Lines 467-482, Table 1-11, Figure 1-22: A comparison of the two models suggests some differences that affect the temperature results: a) The channel geometries and flow characteristics are different. HEC-RAS directly models flow, and they altered the geometry to 1934 conditions. RBM10 used 2010 geometry and they note that they did not alter geometry to the likely change to free-flowing conditions. This could affect temperatures from differences in water depth and width. b) RBM10 uses regional meteorology data from major airports. HECRAS uses local met data. This may be a significant source of error. The airport met stations are far from the river, and data from these locations may be different from local temperatures and wind velocities along the Snake River. This would be especially significant for wind, since that drives evaporation and is a major factor on large rivers and reservoirs.	Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). Please note that model calibration reports were developed for all water quality models and are available by request. In regards to HEC-RAS, this model does have a way to adjust the wind-sheltering coefficients but uses different terminology: wind coefficients a, b, and c. HEC-RAS does change evaporation rates seasonally because evaporation rates depend on temperature and wind speed, similar to the approach used in CE-QUAL-W2. As stated above, the co-lead agencies and USEPA worked collaboratively to compare RBM-10 and the CRSO EIS water temperature models and concluded that the temperature predictions by both models are within a reasonable estimate of the uncertainty bounds. Differences between model estimates should be viewed as a reflection of the uncertainty in the predictive accuracy of the available tools.
6514	47	fraxinus@reachone.com	N/A	4) Lines 536-567, 1.3.10.2 Temperature Comparison to No Action Alternative: These results are key to the analysis, but the presentation is confusing. a) Its not clear how NAA results were analyzed for comparison. Were these depth averaged, tailwater values, or some other value? b) Table 1-14 is not a useful way to present results. Data has been lumped into a single average and the two extremes are shown, along with pooled statistics. This reports very little information about temperatures in the two scenarios. c) One of the challenges of comparing a reservoir to a free-flowing river is that the travel time changes and time lags can create difficulty comparisons. The analysis should evaluate whether changes in travel time are affecting results. d) Travel time can also affect fish exposure to temperatures, and this should be assessed and reported as well. e) The water quality standards are based on daily maximum values. If comparisons are made at a specific location (each dam) then the daily maximums should be compared. f) The entire river should be assessed, not just the dam locations. Data could be pooled by reservoir reaches and by month to compare with cumulative distributions. g) Cumulative distributions are a powerful tool to assess temperature differences between dams and reservoirs. The percent of time and space that temperatures are at different levels has more relevance to salmon habitat.	The No Action Alternative results are the CE-QUAL W2 water temperature output that represents fully mixed conditions at the dam locations, in the tailwater location of each CRS project. These results were compared to the cross section of the RAS MO3 model that is representative of the same tailwater locations (RAS results are always depth averaged). The data shown in Table 1-14 represents annual information and is not broken down into year type analysis. The co-lead agencies feel that this is a sufficient way to compare the two models. The statistics shown are calculated using the same methodology that we used to analyzed each EIS alternative. Regarding water particle travel time, the analysis showed that travel time did change between the No Action (reservoir) versus MO3 (dam breach) scenarios. The water quality models utilize this information when predicting warming and cooling from solar radiation and other coefficients (wind-sheltering, evaporation rates seasonally because evaporation rates, etc.). The system water quality model's extent includes the entire mainstem river, from the international boundary above Grand Coulee Dam to just downstream of Bonneville Dam at Warrendale, Oregon. The co-lead agencies chose to pull model output from the fixed monitoring stations, located upstream and downstream of each dam, since these are the typical locations where data is utilized when making real-time water management decisions and ensuring compliance with water quality standards.
6514	48	fraxinus@reachone.com	N/A	IV. DEIS Chapter 4 1) Lines 52-62: Its good to see the discussion of the RMJOC-II Part 1 findings. However, the footnote on page 4-2 is disturbing (The co-lead agencies expect this study [Part 2] to be published in spring 2020 after release of the draft EIS and will review the study to determine if any information presented in the draft EIS needs to be updated.) If the Part 2 study is close to being published, preliminary results should be available. With the huge investment in RMJOCII, and the quality and significance of the results, its essential that the Part 2 results be presented and included in the analysis. It is of vital importance to evaluate the relative impacts of climate change on the existing system of Snake River dams versus the MO3 option of dam breaching using the best available science, and both the RMJOC-II Part 1 and Part 2 results must be applied to the DEIS analysis to provide an analysis that is comprehensive and up-todate.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS.
6514	49	fraxinus@reachone.com	N/A	2) Lines 97-149, Sections 4.1.2.3 and 4.1.2.4: Loss of snowpack at all but the highest elevations in Canada, and the decline in summer and falls streamflow have enormous implications. More information on the RMJOC-II results in these areas should be provided. What are the magnitude of the changes expected? How does it affect the Alternatives? Does it suggest other alternatives, such as summer and fall drawdown, or partial breach with low level gates for split-season operation?	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Section 4.1 are indicative of changes in Canada.
6514	50	fraxinus@reachone.com	N/A	3) Lines 214-246: The pattern shown of increased flows for future scenarios for the 5th percentile at Ice Harbor Dam should be explored further, especially when flows at Dworschak Dam decrease across the board. The graphs for this information found in RMJOC-II Part 1 report (pp 89-91) show different information from the graphs in the DEIS. The RMJOC-II Part 1 report shows flows shifting earlier and lower, while the DEIS shows flows about the same and with little temporal shift. The differences in this information should be evaluated and either corrected or explained.	The drainage area above Dworshak Dam is a small fraction of the drainage area above Ice Harbor. The hydroclimatology of flows at these two locations are likely to be different. The presentation of streamflow projections in the Draft EIS is different than in RMJOC-II Part 1, however, the underlying data are the same. The Draft EIS presented the range of two emissions scenarios and describes the range statistically. RMJOC-II Part 1 only showed the range of projections from the RCP 8.5 scenario. Additionally, the Draft EIS used more extreme flow percentiles, 5th and 95th, as opposed to 10th and 90th as used in RMJOC-II Part 1. The analysis referenced in RMJOC-II Part 1 presented daily data. The Draft EIS presents data at a monthly time interval. These differences in analyses contribute to some visual differences between the presentation of projections in the two reports, however, the overall patterns and magnitude of projected changes are consistent.
6514	51	fraxinus@reachone.com	N/A	4) Lines 351-355: Although the question posed is important, since it points to methods for adapting to climate change impacts, it is not the only question that should be evaluated. Another key question is: How will future climate change increase or decrease the projected impacts for each scenario? This would be consistent with the purpose of an Environmental Impacts Statement.	The approach for Section 4.2 was to 1) identify potential impacts of climate change to the No Action Alternative and 2) evaluate how each alternative could influence those effects. Where possible, this includes describing how climate change could increase or decrease effects of the measures to resources.
6514	52	fraxinus@reachone.com	N/A	5) Lines 492-493: The statement that the effect of climate change on the MO3 flows will be similar to the NAA is unsupported and contrary to the significant change in river conditions absent the impoundments in the lower Snake River. The impact on the hydrology and hydraulics of other Alternatives will be fundamentally different from the impacts on a free-flowing Snake River in MO3. For the lower Snake Reservoirs flow changes affect reservoir elevations, power generation, navigation and fish flows. For MO3 the impacts would be felt on summer and fall flow volumes, velocities, and time of travel. The effect on the free flowing river will be different, and may be much smaller than the effect on an impounded river. The implications of climate change on flows in the lower Snake in MO3 should be discussed explicitly and in detail, especially focused on summer and fall flow volumes, velocities, and time of travel.	The changes to hydrology and hydraulics described in this Section are limited the effects of climate change and the resolution of the future projections. Section 4.1 reports changes in monthly flow volumes and timing. MO3 is not expected to alter flow volume and timing at this scale. More detailed analyses of the effects of a free-flowing river and hydraulics are provided in Chapter 3.
6514	53	fraxinus@reachone.com	N/A	6) Lines 539-541, Table 4-8: include a row for forest fire impacts, which would have significant impacts on erosion.	Wildfire and its effects of erosion is included in the "vegetation" row.
6514	54	fraxinus@reachone.com	N/A	7) Lines 607-610: This discussion should also make the point the free-flowing river would produce a cleansing of sediments in this reach that would be an environmental benefit to salmon habitat in this reach.	This effect is described in the context of spawning habitat in the anadromous and resident fish Sections of Chapter 3. The Aquatic Invertebrate Section of chapter 3 describes the effect of a transition from silt and sand to more gravel and cobble.
6514	55	fraxinus@reachone.com	N/A	8) Lines 677-733: no discussion is provided of the impacts of climate change on Albeni Fall dam and the Pend Oreille River.	Climate change impacts can be found throughout Chapter 4. Climate change effects on Albeni Falls water quality are described in the first paragraph under Section 4.2.3.1.
6514	56	fraxinus@reachone.com	N/A	9) Lines 776-778: why only surface water temperature? Given the weak stratification and passage through multiple dams, it is likely to increase temperatures throughout the water column. This statement should be corrected.	In this context, surface water temperature refers to the distinction between surface and groundwater, not the lake surface as distinct from other points in a column of surface water.
6514	57	fraxinus@reachone.com	N/A	10) Lines 805-818: a) The discussion in this section is inadequate and misleading. The results from RMJOC-II Part 2 are needed here for a quantitative assessment that links those results to water quality modeling. b) This section provides no evidence to support the assumption that spring temperatures will be higher, including a quantitative assessment is provide to calculate the effects. A shallower, swifter river will have more cooling from surface radiation and bed conduction at night. Time of travel will also allow spring flows from snowmelt to move more quickly through the system with less time to warm. So the effect of climate change on spring temperatures may be less for MO3 than for the NAA c) This section provides no evidence of similar water temperatures in the summer. The pattern of temperatures are likely to be quite different. For the same reasons as noted for the spring, the overall effect of climate change on summer temperature may be less for MO3 than for the other alternatives. Wider daily swings in temperature are likely, but the heat mass of a reservoir may tend to promote a steady increase in temperature rather than relatively quick dissipation of temperatures at night for a free-flowing river. At mid-day temperatures may be higher, but at night they may be cooler. Since modeling of average temperatures shows a significant increase in reservoirs versus the free-flowing river, its quite possible that the change in average temperatures under climate change will be less in MO3 than in the other scenarios. d) Although this section provides no evidence of cooler water temperatures in the fall, this is the most likely outcome that available evidence suggests. The free-flowing river will respond more quickly to longer night and shorter days in the fall, as compared to the months required to dissipate the thermal mass of the reservoirs.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS. The climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). These analyses are documented in Section 4.2.3 for the MO Alternatives and Section 7.8.4 for the Preferred Alternative. Overall, the Preferred Alternative is expected to result in benefits to anadromous salmon and steelhead. The analysis in Section 7.8.4 recognizes that some of the benefits to fish from the Preferred Alternative could be offset by the effects of climate change. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges.
6514	58	fraxinus@reachone.com	N/A	11) Lines 1033-1034, Potential increased water temperature from MO3 in the spring could be further amplified by warming from climate change: Again, this statement is not supported by any evidence, and qualitative arguments suggest that spring temperature may be less affected by climate change under a free-flowing situation. A quantitative analysis with RMJOC-II Part 2 results is needed.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia Basin in still under development and was not available for us in this study. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in

					Chapter 4). The RMJOC-II Part 2 study was still in review at the time of the draft publication and final EIS development. Though the quantitative data from the Part 2 study was not included in this study, the qualitative conclusions were verified with the draft conclusions of the RMJOC-II Part 2 study for the final EIS. The climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). These analyses are documented in Section 4.2.3 for the MO Alternatives and Section 7.8.4 for the Preferred Alternative. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges.
6514	59	fraxinus@reachone.com	N/A	12) Lines 1035-1038: this sentence is misleading. Although climate change may make habitat conditions worse in a freeflowing scenario, they are likely to be far worse in the impounded Alternatives, and the overall effect of climate change will be less on a free-flowing river than in an impounded river.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). Breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges.
6514	60	fraxinus@reachone.com	N/A	13) Lines 1972-1980: This section ignores the likely shift in recreational activities that could occur. Rafting of the Snake River above the Clearwater River is very popular, and there would likely be an economic boost from an expanded rafting industry. This section should explore the possibilities of this alternative recreation industry.	The Recreation Section 3.11.3.5 describes the potential social welfare and regional economic benefits to river recreation, including to recreational activities, such as drift boating, rafting, and kayaking, in the long-term under MO3.
6514	61	fraxinus@reachone.com	N/A	V. DEIS Chapter 5 1) A global comment for this section is the absence of discussion of the unique requirements of Section 303d of the Clean Water Act. A section should be added similar to Section 5.3 to discuss the compliance requirements for the CWA. In general this chapter need a more detailed an accurate of CWA requirements. The CWA does not allow mitigation standards must be met. Therefore, a discussion should be provided regarding how CRSO will meet the standards.	Sections 3.4 Water Quality and 7.7.3 Water Quality present the water quality analysis for all the alternatives. In addition, Chapter 8 describes compliance with all applicable laws, including the Clean Water Act. However, NEPA does not require an EIS to quantitatively evaluate all parameters on the 303d list.
6514	62	fraxinus@reachone.com	N/A	VI. DEIS Chapter 7 1) Lines 585-589, Table 7-1, Part 3: Environmental: use of Standards misused a) Water quality standards compliance discussed briefly under MO4, very briefly under a few, but not under others. All misstate or provide incomplete assessments of compliance with WQS (e.g. mitigate standards).	Table 7-1 Part 3 describes major effects to environmental, economic, and social resources for purposes of comparing alternatives. Detailed descriptions of water quality effects for each of the alternatives are described in Section 3.4 and Section 7.7.3. Following the release of the draft EIS, state water quality standards for TDG in Oregon and Washington have been updated.
6514	63	fraxinus@reachone.com	N/A	2) Lines 1998-2015, p 7-80, Section 7.7.3.1: no mention of temperature impairment in Pend Oreille River. No change from NAA does not constitute compliance with clean water act.	Discussion of the existing conditions at Pend Oreille River are described in Section 3.4.2.1, Water Quality. As described in Section 3.4.2.1, a TMDL was established for the Pend Oreille River in 2011. As described in Section 2.4.2, No Action Alternative, the conditions at the time the EIS was initiated in 2016 are used as the baseline condition for comparing environmental effects of the alternatives. This complies with 40 CFR Section 1502.14 and the Council on Environmental Quality's 40 Questions (Federal Register Vol. 46. No 55 page 18026) with regard to the No Action Alternative, which states "the No Action alternative may be thought of in terms of continuing with the present course of action until that action is changes." Chapter 8 of the EIS discusses the co-lead agencies' compliance with applicable laws, including the Clean Water Act.
6514	64	fraxinus@reachone.com	N/A	3) Lines 2072-2091, p 7-82, Section 7.7.3.2: misstatement and misinterpretation of standards for upper Columbia River	The text references in the comment do not pertain to compliance with water quality standards in the upper Columbia River. The referenced text describes effects to water quality that are anticipated from implementation of the Preferred Alternative. Discussion of compliance with water quality standards is included in Section 8.5 of the EIS.
6514	65	fraxinus@reachone.com	N/A	4) Lines 2134-2158, p 7-84, Section 7.7.3.3: misstatement and misinterpretation of standards for the lower Snake River	The text references in the comment do not pertain to compliance with water quality standards in the lower Snake River. The referenced text describes effects to water quality that are anticipated from implementation of the Preferred Alternative. Discussion of compliance with water quality standards is included in Section 8.5 of the EIS.
6514	66	fraxinus@reachone.com	N/A	5) Lines 2195-2215, p 7-85 & 86, Section 7.7.3.4: misstatement and misinterpretation of standards for lower Columbia River.	The text references in the comment do not pertain to compliance with water quality standards in the lower Columbia River. The referenced text describes effects to water quality that are anticipated from implementation of the Preferred Alternative. Discussion of compliance with water quality standards is included in Section 8.5 of the EIS.
6514	67	fraxinus@reachone.com	N/A	6) Lines 1997-2268, Section 7.7.3, general: The Columbia and Snake Rivers are listed as impaired under C=CWA 303d. This is not mentioned. Saying it is no worse under PA than under NAA, is saying that the PA does nothing to improve temperature impairments.	Discussion of the existing water quality conditions, including those listed on a 303(d) list, is described in Section 3.4, Water Quality, and Appendix D. As described in Section 2.4.2, No Action Alternative, the conditions at the time the EIS was initiated in 2016 is used as the baseline for comparing environmental effects of the alternatives. This complies with 40 CFR Section 1502.14 and the Council on Environmental Quality's 40 Questions (Federal Register Vol. 46. No 55 page 18026) with regard to No Action Alternative which states "the No Action alternative may be thought of in terms of continuing with the present course of action until that action is changes." Section 8.5 of the EIS discusses the co-lead agencies compliance with the Clean Water Act.
6514	68	fraxinus@reachone.com	N/A	7) Lines 2269-3158, Section 7.7.4, general: There is very little discussion about temperature effects. The DEIS makes little mention of current research on temperature impacts on migration and the use of cold water refuges, even though it is mentioned in Appendix D.	Section 7.7.4 includes a general description of the temperature impacts on fish migration. A more detailed discussion of temperature effects are described in Appendix D.
6524	1	Dave Ward	Grays Harbor Public Utility District	To that end, we feel that the final decision concerning the operations of the CRSO must be one that takes all areas of rivers impact into account and will not have a negative impact on the reliable power supply which utilities throughout the region rely upon to keep the lights on for residential, commercial and industrial customers. In addition to concerns in the area of energy production, the Grays Harbor PUD believes the existing hydroelectric facilities, specifically the Lower Snake River Dams have far reaching, positive impacts on the surrounding communities. The economies of these areas depend on the dams in the form of millions of dollars in recreation through rafting, kayaking, canoeing and boating on the Columbia and Lower Snake River and lakes and reservoirs formed by the dams. In terms of navigable waters, commercial barge traffic on the Snake and Columbia River moves 8-million tons of commercial cargo between Portland and Lewiston. Without this relatively clean method of transportation facilitated by the Lower Snake River Dams, thousands of carbon emitting vehicle trips would be needed to move those products, to say nothing of the impacts additional vehicle traffic would have on the Washington state transportation infrastructure. Removal of the dams would also have a serious impact on the irrigation systems used by thousands of farmers throughout the Columbia and Snake River Basins, which use the river runoff to water 7.8 million acres of Northwest farmland. In short, the dams on the Columbia and Snake River's impact millions of lives, jobs and households and any actions taken towards their removal would negatively impact Washington and the Pacific Northwest.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. The EIS includes extensive analysis of the effects of MO3 to power (Section 3.8), irrigation (Section 3.12), navigation and transportation (Section 3.10), and recreation (Section 3.11).
6524	2	Dave Ward	Grays Harbor Public Utility District	In terms of power generation, the Grays Harbor PUD believes in an integrated power generation system in which existing technologies are combined with emerging methods. This calls for the preservation of existing hydroelectric facilities on the Columbia and Snake Rivers. At the same time, the utility recognizes the need for environmental concerns to be addressed, such as the preservation of salmon runs on the two rivers. To that end, we realize that steps must be taken to give those runs a chance at recovery. We feel the preferred alternative suggested in the draft EIS of increased spill and additional mitigation efforts designed to help fry reach open waters is an acceptable method, but needs to be monitored closely to verify fry survival improvement and not create more harm. Analysis by trade groups has found that the increased spill over federal dams will have an impact on power costs, perhaps as high as twopercent; on top of the increases the Bonneville Power Administration calculates every two years as part of their power contracts. While the increased cost is certainly regrettable, we believe it is an inevitable and acceptable compromise which will allow the Grays Harbor PUD and others like it throughout the region to maintain the mission of reliable utility services at the lowest practical cost.	Consistent with the comment, the co-lead agencies developed a Preferred Alternative that considered the need for an adequate, efficient, economical and reliable power supply, combined with the need to meet other authorized CRS purposes. The agencies additionally committed to mitigating for impacts to fish and wildlife impacted by CRS operations. The Preferred Alternative shows a rate impact relative to the No Action Alternative of 2.7%, which is among the smallest impacts to rates considered in the EIS. See EIS, 7.7.9.1, Rate Sensitivity Analysis, Table 7-32 of the Draft EIS. The power estimates presented in the EIS are a comparison to the No Action Alternative, rather than the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control. See EIS Section 3.7.3.1, at 3-817 in the Draft EIS. Regarding the stated concern about potential harms of increased spill, the Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the biological models and will help to determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored, as will the effects to generating resources around the basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
6524	3	Dave Ward	Grays Harbor Public Utility District	We applaud the DEIS findings that recognize in no uncertain terms the negative impact the removal of the Lower Snake River Dams would have on the reliable power supply which utilities rely on throughout the region. The reliability of the power supply flowing from the dams of the Federal Columbia River Power System (FCRPS) is a tremendous benefit to the residents of Washington state. The water behind the dams serves as a "load following" system which can be ramped up or down by increased or decreased water flow, depending on the varying electrical load of the region. The four dams on the Lower Snake River are a critical component of that system. With production of over 1000 average megawatts of clean and reliable energy (enough energy to power roughly 800,000 homes), the dams have been identified by the Bonneville Power Administration as a key component of the FCRPS's mission of supporting peak power generation. It is important to remember that while power usage in the region is growing, other base load resources are being removed.	The statement about the peaking capability and characteristics of hydropower and their value in serving load for the Northwest is consistent with the findings of the EIS. See Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907; Section 3.7.3.5, Summary of Effect, page 9-935, in the Draft EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6524	4	Dave Ward	Grays Harbor Public Utility District	The retirement of coal generation facilities in Washington, Oregon and Montana is estimated to reduce the power supply by over 3000 megawatts. Without reliable resources to replace that energy, a growing population and increased energy use in the residential, commercial and transportations sectors, the region faces the possibility of a capacity shortfall, similar to the one that struck the West Coast in 2000-2001. Given that fact, we firmly believe that now is not the time to remove base load resources from the FCRPS. While additional spill over the dams may mean an increase in energy and transmission rates from the Bonneville Power Administration, it is a far cry from the billions of dollars that would be needed to replace the base load resources provided by the FCRPS. Each community that relies on the affordability of hydropower would see a crippling increase in rates, an increase that will be passed on to utility customers. In Grays Harbor, many PUD customers are already struggling to get by with existing costs from the current infrastructure. To increase the burden by asking them to help foot the bill for new technologies that lack the affordability and reliability that have made hydropower the dominant power resource in the region for nearly a century is an expense many, quite literally, cannot afford	The concerns voiced in the comment regarding potential rate increases and the reliability of hydropower are consistent with the findings of the EIS. See draft EIS, Section 3.7.3.5, at 3-918-924 and Table 3-166. Consistent with the comment, the EIS findings indicate that the region would likely experience a significant regional deficit of power given upcoming coal retirements, which would require adding additional power resources to maintain power system reliability at the No Action Alternative levels. See Sections 3.7.3.3 through 3.7.3.6 in the draft EIS. The comment that increases in utility costs can adversely affect vulnerable groups is also consistent with discussions in the EIS. The Environmental Justice analysis (Section 3.18.3 and Chapter 7 of the EIS) provides further detail on the potential disproportionate effects to Tribal, low-income and minority populations.
6524	5	Dave Ward	Grays Harbor Public Utility District	In addition to reliability, the Lower Snake River Dams and the FCRPS have made Washington's power supply one of the cleanest in the nation. That fact helped the state pass the Clean Energy Transformation Act in 2019, the most meaningful energy legislation of the last decade. With a goal of 100% clean energy by 2045, the loss of the clean, emission free energy produced by the dams would deal that goal a severe blow and perhaps force the state to seek energy on the market from emitting resources, thereby working against legislation brought about by cooperation and compromise. Our support of federal hydro power is not to be mistaken for opposition to new energy resources in general. Advances in wind, solar and other renewable resources, coupled with progress in energy storage may well be the future of our industry. However at this time, those resources fall short both from a reliability and affordability standpoint. In time, they may overcome those shortcomings. With the clean and reliable energy resources provided by the FCRPS, the energy exists to allow innovation and invention to run its course and for new resources to be perfected and take their place in an integrated regional power system that will allow Washington to continue its role as a leader in clean and renewable energy.	This comment makes various statements about hydropower and the Federal Columbia River Power System that are consistent with information presented in the EIS in Sections 3.7 and 3.8. The EIS also acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options.
6533	1	kate@crsoa.net	N/A	A functioning upriver system provides the link to the Pacific Northwest export economy critical to so many workers. If navigation is obstructed, grain suppliers and shippers will experience increases in transportation and storage costs of 50 to 100%. The highways, rail, and grain elevator networks along the Columbia River would need over $1 billion in capital investments to adapt. This includes hundreds of miles of shortline rail track that have been abandoned; new rail; major highway improvements; and retrofits for grain elevators that do not have rail-loading capabilities. Therefore, CRSOA concurs with the decision to reject Multiple Objective 3 Alternative (MO3), which obstructs navigation, increases emissions, has an adverse impact on poor and rural communities, and will increase sedimentation in the Columbia River.	The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the furthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most negatively impacted. Section 3.10 of the Draft EIS provides an evaluation of the Columbia-Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, low air emissions relative to other transportation modes, potential regional economic effects, and other social effects that could occur under MO3. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear and tear costs could occur. The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5.
6533	2	kate@crsoa.net	N/A	I. The Preferred Alternative Appropriately Balances the Objectives of the Co-Lead Agencies, Enhances Environmental Objectives, and Maintains Navigation. U.S. Senator Patty Murray recently said that Washington is the most trade dependent state in the nation. With about 1500 vessels calling the Columbia River each year, maritime commerce accounts for approximately 50 million tons of foreign trade and $21 billion in cargo value annually. Various studies estimate that over 40,000 jobs are dependent on maritime trade related to the Columbia and Snake River system. Numerous federal laws have established the run-of-river and storage projects on the Columbia and Snake rivers that, along with maintenance of the navigation channel, ensure a reliable maritime industry that safely, inexpensively, and reliably move goods. The Flood Control Act of 1962, for example, requires that the navigation channel of the Columbia-Snake River system not fall below fourteen feet. See Flood Control Act of 1962 (1962 Act), Pub. L. No. 87-874, Title II (1962) (providing that the depth and width of the authorized channel in the Columbia-Snake River barge navigation project shall be established as fourteen feet and two hundred and fifty feet, respectively, at minimum regulated flow). The system needs to be operated to meet the minimum requirements of the 1962 Act and the requirements of other applicable federal laws. CRSOA appreciates that the Preferred Alternative takes an approach to comply with the federal laws that established the Columbia River hydroelectric and navigation system while also meeting other objectives of the CRSO EIS and requirements of the maintenance and operation of the Columbia River System (CRS). As reflected in the Preferred Alternative, barging is an efficient and environmentally preferable method of transportation. More wheat is transported along the Columbia-Snake River System than anywhere else in the U.S. By maintaining a reliable marine navigation system the agricultural products get to the terminals on the lower river and are available for export. One barge with tow can ship the equivalent goods of 1.4 100-unit freight trains, or 538 semi-trucks. Barging is nearly 40% more fuel-efficient than freight trains, and 270% more fuel-efficient than semi-trucks. In 2018, it would have taken 38,966 rail cars or 149,870 semi-trucks to move the 3.9 million tons of cargo shipped on the Snake River alone. If we lose the system of dams and locks that enable barge shipments, the change to trains and trucks would congest our communities, increase greenhouse gas emissions, and decrease air quality. This efficient and low-cost mode of transportation protects the farmers and economically stressed communities of eastern Washington and Oregon. Navigation along the Columbia and Snake Rivers is critical to the movement of crops and goods. This mode of transportation is relied upon by farmers and communities for low-cost, efficient transport. Federal laws require the ongoing maintenance of the Columbia and Snake River navigation channel. The Preferred Alternative maintains this life-blood of the Pacific Northwest economy.	Thank you for your comment. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. The comment is consistent with the findings in the EIS, in that access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Northwest currently, and removing that option would increase transportation costs for grain producers, among other effects.
6533	3	kate@crsoa.net	N/A	II. Co-Lead Agencies Appropriately Rejected the Multiple Objective 3 Alternative and Cannot Adopt an Alternative that Includes Dam Breaching. As acknowledged by the co-lead agencies, MO3 does not allow for the operation of the CRSO in furtherance of the Congressionally authorized purposes of operating and maintaining the lower Snake River dams for navigation, hydropower, irrigation, and recreational benefits. The economic and social harm caused by MO3 would far outweigh the speculative fish survival benefits suggested in the EIS. CRSOA agrees with and supports co-lead agencies decision to not adopt the MO3 alternative, and submits comments on the negative impacts on air quality, climate, disadvantaged communities and sedimentation. a. The Co-lead Agencies Cannot Adopt an Alternative that Obstructs Navigation. As noted throughout the EIS, the co-lead agencies do not have authority to implement a dam breaching solution. At Section 2.4 of the EIS, the co-lead agencies confirm that [n]ew congressional authority and associated funding would be required to implement the dam breaching measures evaluated in the EIS. Multiple acts of Congress authorized and funded the dams and hydropower systems on the Columbia Snake River system and additional congressional action would be necessary to alter that framework. Acts of Congress have also established the rights of navigation on the Columbia and Snake Rivers. Laws such as the Rivers and Harbors Acts, Water Resources Development Act, Flood Control Act, and the Energy and Water Development Act are all relied upon by the co-lead agencies to develop the waterway navigation system and require that the co-lead agencies, primarily the Corps of Engineers, maintain those projects. The Flood Control Act of 1962, in particular, establishes that a minimum depth be maintained for navigation on the Columbia-Snake River. [T]he depth and width of the authorized channel in the Columbia-Snake River barge navigation project shall be established as fourteen feet and two hundred and fifty feet, respectively, at minimum regulated flow. See Flood Control Act of 1962 (1962 Act), Pub. L. No. 87-874, Title II (1962). No law grants the Corps discretion to regulate the navigation channel outside of these parameters, including the National Environmental Policy Act or Endangered Species Act. See In re: Operation of the Missouri River System No. 04-2737, 2005 U.S. App. LEXIS 17224 at *26-*27 (8th Cir. Aug. 16, 2005) (Case law supports the contention that environmental- and wildlife-protection statutes do not apply where they would render an agency unable to fulfill a non-discretionary statutory purpose or require it to exceed its statutory authority.). Under NEPA, the lead agency is not required to analyze the environmental impacts from actions where it has no discretion to prevent the action that causes those environmental impacts. Department of Transportation v. Public Citizen, 541 U.S. 752. 772 (2004) (where agency does not have control or discretion over the decision or outcome and thus any incidental environmental effects resulting from the decision, no analysis of those effects are required under NEPA). Because the co-lead agencies lack authority and discretion to remove dams or obstruct navigation, they had no obligation to assess dam breaching in the EIS. CRSOA, nevertheless, appreciates the co-lead agencies efforts in this regard in that those efforts allowed the agencies to analyze issues raised by the judicial branch and in public comments, providing technical review that demonstrates the adverse outcomes from dam removal when analyzed objectively. The conclusions demonstrate that when dam removal is assessed in the context of the various categories of impacts, it cannot meet the project objectives.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Table 7-1 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives.
6533	4	kate@crsoa.net	N/A	b. Obstructing Upriver Shipping by Removing Snake River Dams Will Increase Emissions and Harm Air Quality. Any alternative that involves dam removal, such as MO3, will result in shipping activities shifting from barge to road and rail transport. Barge transportation is an efficient mode of transportation with relatively low carbon emissions per ton-mile of freight compared with truck or train transportation. Transportation-related emissions, including diesel particulate and carbon emissions would significantly increase. In A Modal Comparison of Domestic Freight Transportation Effects on the General Public: 20012014 (January 2017), the researchers found that barges can move a ton of cargo 647 miles with a single gallon of fuel. In contrast, trains can move the same ton of cargo 477 miles per gallon, and trucks can move the same ton of cargo 145 miles per gallon. Similarly, the Corps of Engineers has compared one barge tow on the Snake River to nearly 530 truckloads carrying the same commodity. When roundtrips are calculated, the additional emissions caused by the switch are significant. Moreover, the CRSO EIS fails to fully account for the congestion due to increased traffic along the Columbia River and I-5 corridors, further increasing emissions. When Terminal 6 at Port of Portland was forced to shut down,	The findings of the emissions analysis for Multiple Objective alternative 3 in Section 3.8 in the Draft EIS are consistent with this comment. In addition, the EIS analyzed the modal comparison report cited by the comment and relies on the emissions factors from this report to estimate the emissions effects. The EIS acknowledges potential effects on air quality from increased truck traffic by region (see Draft EIS Section 3.8.3.5) and also assessed potential effects of increased highway usage and highway congestion (see Draft EIS Section 3.10.3.5). This congestion does not affect the number of farm trucks leaving farms, and thus, does not affect the EIS greenhouse gas emissions analysis as the EIS relies on emissions per ton-mile estimates as opposed to per gallon of fuel used, which could be affected by idling and congestion as mentioned by the comment.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				for example, container shipments were forced on roadways and rail resulting in congestion, idling, and an increase in localized and general emissions (greenhouse gases and particulate matter). Similar emissions, but on a larger scale, will occur if navigation is stopped because of dam breaching.	
6533	5	kate@crsoa.net	N/A	c. Dam Removal Will Increase Fossil Fuel Usage by the Power Sector. Dam removal would further increase the need for additional power resources to replace the reduced hydropower generation. That is because fossil fuel generation would be necessary to augment the replacement resource in order to meet peak demand, seasonally or even daily, in light of the reduction in hydropower generation caused by dam breaching. And even if a zero-carbon replacement alternative is possible, those resources would not be built by 2022, which means that fossil-fuel power plants would continue to be necessary to meet demand. While the type and location of additional power resources is uncertain, increased generation from existing fossil fuel plants, particularly natural gas capacity, would further degrade air quality and increase greenhouse gas emissions compared to the hydropower being replaced.	The findings of the emissions analysis for Multiple Objective Alternative 3 (MO3) is consistent with this comment. Even assuming all renewable replacement resources are built or acquired to maintain regional power reliability under MO3, the analysis finds some increase in fossil fuel generation, resulting in a 2.7 percent increase in regional CO2 emissions relative to the No Action Alternative.
6533	6	kate@crsoa.net	N/A	d. Dam Removal and Obstructing Marine Commerce Will Disproportionately Impact Low Income and Underserved Populations. As noted in the CRSO EIS, environmental justice communities will experience significant adverse effects resulting from broader impacts to power generation and transmission, navigation and transportation, water supply, recreation, and cultural resources. The regions dryland farmers will be significantly impacted by the loss of marine commerce. There are over 1,100 dryland farmers operating in the affected upriver areas, with average pretax income of only $40,211 per establishment. (USDA 2017 Census). The added costs of shipping crop by truck or rail would put many farmers at risk of bankruptcy or foreclosure. The removal of renewable baseload hydropower will disrupt a power system already at risk of losing the baseload supply needed for grid reliability. As noted in the news story Will there be enough electricity after coal plants shut down? (KGW, December 18, 2019), the Pacific Northwest is removing baseload power at a fast pace while increasing the demands on the grid. The result could be rolling blackouts and utility rate increases. The impacts from the lack of grid reliability and resilience are felt disproportionately by the disadvantaged and small business.	The EIS analyzed two resource portfolios to replace the hydropower generation of the lower Snake River dams, both of which maintain regional power system reliability. See EIS, Section 3.7.3.5, at 3-904-910. Thus, a decrease in the reliability of the power system and increased risk of blackouts would be unlikely to occur and there would not be additional safety concerns if the replacement resources were put online. The EIS does acknowledge potential safety concerns if resources were not built before breaching (see EIS, Section 3.7.3.5 at 3-935). The statement that without resource replacement, regional power reliability would decline under MO3 is consistent with the findings of the EIS. The EIS also finds, consistent with this comment, that increasing retirement of coal power plants would adversely affect regional power reliability (see Section 2.3 of Appendix H, Sensitivity of LOLP to Assumptions about Coal Capacity).
6533	7	kate@crsoa.net	N/A	e. Dam Removal Would Have Significant Sedimentation Impacts on Lower River Navigation and Other Water Users. The co-lead agencies note that dam breaching will result in downriver sedimentation. The effects from dam breaching would be major and would be the largest influence on sediment process effects. (CRSO EIS at 6-30). Such sedimentation will increase downriver navigation channel maintenance costs, adversely impact private and port riparian properties, and could result in disruption of downriver marine transportation. For the reasons set forth in the CRSO EIS and here, breaching the dams would not allow the co-lead agencies to operate and maintain the dams for their congressionally authorized purposes of navigation, hydropower, envisioned recreational benefits, and water supply for irrigation purposes.	The co-lead agencies included the Breach Snake Embankments measure in Multiple Objective Alternative 3 (MO3) to be responsive to the Opinion and Order from the District Court of Oregon and to the many comments submitted during the scoping period, despite the potential for that measure to conflict with the four lower Snake River dams' congressionally authorized purposes. Direct and indirect effects of MO3, as compared to the No Action Alternative, include downriver sedimentation as described in cumulative effects Table 6-11 (Section 6.3.1.2.4). Near-term sedimentation effects following the MO3 Breach Snake Embankments measure are predicted to last up to ten years (depending on the hydrologic regime) as legacy sediment deposits within the former reservoirs are incrementally eroded and re-deposited throughout the lower Snake Reach. Near-term sedimentation effects are expected to be particularly large in the upstream end of Lake Wallula on the Columbia River. The impacts of sediment deposition at left bank recreation and boat-launch sites below the Snake confluence would likely be permanent. Long-term sedimentation effects would include continued deposition in quiescent areas prone to shoaling as a result of annual sediment delivery that had previously been trapped by the lower Snake River dams, but not directly interfere with Columbia River navigation. Mitigation actions for these potential impacts to navigation are detailed in Section 5.4.3.5 and propose dredging to maintain this reach of the Federal navigation channel. Likewise, public and private port facilities both near the confluence of the lower Snake River and on the left bank of Lake Wallula would need to conduct sequential dredging in order to avoid interruptions in service and maintain access to the navigation channel. Dredging mitigation for maintaining the Federal navigation channel would be a Corps' expense, while dredging to maintain port facilities and access to the Federal navigation channel would not be a Corps' expense. Dredging operations are expected to remain similar to No Action Alternative in the remaining reach of the Columbia River navigation channel.
6540	1	smcclintock@ugcpnw.com	N/A	The DEISs preferred alternative focuses on benefitting fish recovery using water management measures while balancing our regions critical needs for water, power, navigation and trade. More wheat moves on this system than anywhere in the country because its the most cost effective and environmentally sound way to transport commodities. A single barge ships the equivalent goods of 134 semi-trucks and is more fuel efficient. For additional context into this staggering figure, United Grain utilizes 320 barges annually to move wheat along the river system. If barging were eliminated as a mode of commodity transit, United Grain would need to utilize over 42,800 trucks or 11,430 jumbo hopper rail cars a year to replace barging.	Thank you for your comment. The EIS includes extensive analysis of the effects to navigation and transportation in Section 3.10 from MO3.
6540	2	smcclintock@ugcpnw.com	N/A	Our economies are not prepared to function with the loss of barging on the Columbia and Snake Rivers. Our highway, rail and grain elevator network would need over $1.1 billion in capital investments just to adapt. The loss of barging as a transportation option will result in a 50% to 100% increase in transportation and storage cost for grain shippers like United Grain. For an industry that competes on the world stage, these increased costs could have severe consequences on the U.S. ability to compete in the global marketplace.	The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. Evaluating the impact of removing the lower Snake River locks and barge navigation above Pasco, Washington, is completed using a transportation optimization model that does not allow shipments on river terminals along the lower Snake River. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the furthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most negatively impacted. Note, cost scenarios for specific farmers are presented in the Regional Economic Effects Section in Section 3.10.3.5.
6540	3	smcclintock@ugcpnw.com	N/A	Over time, improvements to the dam system have made it possible for over 95% of fish to pass through them on their journeys up and down the river and fish populations on the Snake River have trended upward for the past 25 years. There is, however, no doubt salmon recovery will require more work. The most current science from the National Oceanic and Atmospheric Administration finds conditions in ocean waters need to improve for fish numbers to increase. These findings are a clear indication that we must consider the entire ecosystem that salmon depend on and not limit our focus to the dams on the Columbia-Snake River System, where so much investment and improvements have created world-class fish passage infrastructure. The DEIS rightfully recognize this and calls for action outside of the Columbia-Snake River System to accelerate recovery efforts.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those you mention here. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. This EIS analyzes the effects of operation, maintenance, and configuration of the CRS projects. Both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies, also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. With respect to the Preferred Alternative, the fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals.
6543	1	N/A	N/A	The Draft EIS also fails to fully address the significant impact that the dams along these river systems have on the critically endangered Southern Resident orca population. Accepted science indicates that restoring the lower Snake River would lead to stabilization of Chinook runs and provide critical food sources for the Southern Resident orca.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
6544	1	srkiefer@cableone.net	N/A	There needs to be a paragraph outlining the legal, cultural, economic, and ecological costs if the listed fish (especially from the Snake River) are allowed to go extinct.	An analysis of the legal, cultural, economic, and ecological costs would be appropriate if a selected alternative were likely to lead to an extinction. While some alternatives that were modeled are projected to decrease productivity for some ESUs/DPSs, abundance was not projected to reach extinction. While there is uncertainty based on the potential reduction in latent mortality associated with CRS operations, the Preferred Alternative has the potential to provide improvements to the abundance of salmon and steelhead stocks returning to the Snake River.
6544	2	srkiefer@cableone.net	N/A	An alternative that must be included in the final EIS is missing from this draft, namely springtime spillway crest drawdown. Springtime spillway crest drawdown would substantially increase SARs with the dramatically improved migration conditions through the reservoirs and at the dams during the smolt migration, while still allowing for hydropower production during the periods we need it (summer and fall), and the barges would be able to operate for of the year. This alternative should substantially improve SARs while still allow for most of the current industrial benefits.	The co-lead agencies evaluated a measure that varies slightly from the suggested action. In order to increase travel time under MO4, the agencies considered "Reservoir drawdown to Minimum Operating Pool." This measure would draw down the lower Snake River and lower Columbia River projects to lower elevations to reduce travel times for juvenile fish out-migration during the spring and summer. For more information, please see Chapter 2, Section 2.4.6.1. The co-lead agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in relevant literature. These alternatives represent a reasonable range of alternatives for the maintenance, configuration, and operation of the CRS.
6544	3	srkiefer@cableone.net	N/A	I. Delayed mortality: Delayed mortality is much more important than any other factor in determining whether and how best to recover wild stream type Chinook, sockeye, and steelhead from the Snake River. I am very disappointed that some 20 years after the PATH results were unfairly shoved aside, and the resulting 2000 EIS and BiOp identified delayed mortality as the critical uncertainty even though the PATH models had indicated it was substantial, this draft EIS does not adequately address the growing body of empirical data demonstrating the magnitude of delayed mortality for Snake River fish. The draft EIS does acknowledge that the magnitude of delayed mortality is critical in determining what measures are most likely to be effective, and how much so. One element, delayed mortality, stands out as particularly important in explaining the models different predictions. These results highlight the importance of how latent mortality is considered in the analysis and the strong effect it has on the predicted results.	The agencies used current, high-quality modeling information consistent with NEPA and did not rely on information contained in the Plan for Analyzing and Testing Hypotheses (PATH) Weight of Evidence Report (ESSA Technologies 1998), which is over 20 years old and does not reflect current CRS operations. Latent mortality effects were considered and factor prominently in the decision on the Preferred Alternative. Further, the model results presented in Section 3.5 and Chapter 7 address latent mortality. Latent mortality is captured directly in the CSS model for SARs and abundances, and is overlaid with several assumed values (10%, 25% and 50% reductions in latent mortality) in the NMFS Lifecycle model results. Delayed mortality in the ocean due to CRS dam passage is discussed throughout the CRSO EIS.
6544	4	srkiefer@cableone.net	N/A	The glaring biological inadequacy of this draft EIS is the lack of coverage of productivity and survival differences between wild Snake River stream type Chinook and steelhead, and similar populations from other mid-Columbia tributaries. There is no mention that over 20 years ago approximately 25 of	The agencies used current, high-quality modeling information consistent with NEPA and did not rely on information contained in the Plan for Analyzing and Testing Hypotheses (PATH) Weight of Evidence Report (ESSA Technologies 1998), which is over 20 years old and does not reflect current CRS operations. The comment acknowledges that PATH is out of date. A variety of published and unpublished studies have addressed patterns of Smolt-to-Adult return (SAR) among populations of

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the Regions top Fisheries Scientist spent 5 years on this topic (PATH), and concluded that delayed mortality was likely substantial and held the key to recovery. The spawner/recruit data from the John Day and Snake Rivers wild stream type Chinook populations used by PATH has continued to be collected, this now over 60 year data set continues to support and strengthen the PATH conclusion that latent mortality for Snake River fish is substantial and holds the key to recovery. Since PATHs conclusion of substantial delayed mortality for wild Snake River fish based upon this spawner/recruit data, PIT tag SAR data from more mid-Columbia tributary wild/natural stream type Chinook and steelhead populations has become available. This data clearly indicates that similar wild/natural stream type Chinook and steelhead from other mid-Columbia tributaries (Yakima, Umatilla, John Day, and Deschutes) follow the same pattern of response to ocean conditions, yet consistently have much higher SARs than smolts from the Snake River. Smolts from all these populations migrate during a similar time frame, encounter the same bird and fish predators, enter the same ocean, and the returning adults encounter similar conditions. The only biologically logical reason that all these other mid-Columbia tributaries wild/natural stream type Chinook and steelhead populations consistently have much higher SARs is that there is substantial delayed mortality caused by the four lower Snake River Dams. These two independent empirical data sets clearly indicate substantial delayed mortality for wild Snake River stream type Chinook and steelhead and must be used to help clear up the critical biological uncertainty in this draft EIS. The degree to which latent mortality is affecting salmon and steelhead is one of the critical uncertainties in this EIS analysis. These results and their implications for recovery must be thoroughly covered and discussed in the final EIS.	salmonids occurring in more interior and coastal locations. The co-lead agencies do not generally support comparisons of SARs between populations as evidence of latent mortality. The Independent Science Advisory Board has repeatedly questioned that line of evidence and has recommended that the CSS not conduct upstream/downstream comparative studies. For example, see ISAB/ISRP 2007-6 and ISAB 2020-1. NMFS carried out a seven-year study addressing the impacts of multiple dam passage on smolts tagged at Lower Granite dam that passed eight dams in-river, versus those barged and released at McNary Dam (Marsh et al. 2015). No clear evidence was observed for delayed mortality due to multiple dam passage, although they observed an effect of time of release. Latent mortality effects were considered and factor prominently in the decision on the Preferred Alternative. Further, the model results presented in Section 3.5 and Chapter 7 address latent mortality. Latent mortality is captured directly in the CSS model for SARs and abundances, and is overlaid with several assumed values (10%, 25% and 50% reductions in latent mortality) in the NMFS Life Cycle model results. Delayed mortality in the ocean due to CRS dam passage is discussed throughout the CRSO EIS.
6544	5	srkiefer@cableone.net	N/A	I have concerns about both of the models described. The LCM assumption of little delayed mortality for Snake River fish is contradictory to the above described pattern in wild/natural stream type Chinook and steelhead SARs for mid-Columbia tributary populations. Without substantial delayed mortality for Snake River wild/natural stream type Chinook and steelhead (as assumed by the LCM model), there would be little hope for recovery of these populations. My concern with the CSS model is that it appears to overweigh the affect of powerhouse passage on delayed mortality.	The co-lead agencies do not support comparisons of SARs between populations as evidence of latent mortality. The Independent Science Advisory Board has repeatedly questioned that line of evidence and has recommended that the CSS not conduct upstream/downstream comparative studies. For example, see ISAB/ISRP 2007-6 and ISAB 2020-1. There is substantial variation in mean SAR among both wild and hatchery populations within lower Columbia, mid/upper Columbia and Snake ESUs of Chinook and steelhead, with potentially many confounding factors besides distance to the ocean.
6544	6	srkiefer@cableone.net	N/A	Until recently, increased spill mostly occurred when flows were above powerhouse capacity. These higher flows and spill levels resulted in not only reduced powerhouse passage rates but also increased water velocities, cooler water temperatures, and increased turbidities in the entire lower Snake River. Increasing voluntary spill does not improve migration conditions through the reservoirs, only at the dams, and the likely small improvement for in-river w/n smolt SARs with the preferred alternative will likely be undetectable. Recent low SARs of Snake River uncollected w/n Chinook and steelhead smolts, during a period of increasing voluntary spill, as compared to their transported cohorts and other mid-Columbia tributaries reported in recent CSS annual reports supports this concern.	The commenter is correct in that increased spill will not improve reservoir migration conditions, but will further reduce the proportion of fish that pass through powerhouses (PITPH). The CSS model predicts that Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative.
6544	7	srkiefer@cableone.net	N/A	Additionally, Im concerned that the lack of detectable improvements in SARs from implementing the preferred alternative will be used raise doubt about the likelihood that springtime spillway crest drawdown or dam breach would substantially improve SARs.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is predicted to benefit salmon and steelhead. It also meets the other objectives for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
6544	8	srkiefer@cableone.net	N/A	II. Biases in favor of commercial status quo and the preferred alternative: Combining all listed Chinook and steelhead from the Columbia Rivers in one EIS, detracts and dilutes the focus from the unique issues and options for recovery between the Snake and upper Columbia populations.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.
6544	9	srkiefer@cableone.net	N/A	Discussing historic floods in the Introduction is unnecessary; and without highlighting that none of the alternatives considered substantially affect CRS flood control reinforces the misconception by some that the four lower Snake dams provide substantial flood control. I recommend that the two sentences about large historic floods be removed. The last sentence of the paragraph must be changed to something like. Today, the CRS provides flood risk management for communities along the river, and none of the alternatives considered, including breaching the four lower Snake Dams, would substantially affect this critical role of the CRS.	Maintaining FRM operations of the Columbia River System has informed both the alternative development and evaluation process. As stated in the Purpose and Need Statement of the EIS (Section 1.2), one of the purposes of the EIS is to 'Provide for a reliable level of FRM by operating the CRS to afford safeguards for public safety, infrastructure, and property'. As stated in Chapter 1, Section 1.2 of the EIS, the lower Snake dams are not authorized for flood risk management, and as reported in Section 3.9, Section 7.7.11, and Table 7-1, there is no elevated flood risk for any of the EIS Alternatives.
6544	10	srkiefer@cableone.net	N/A	The transportation paragraph reads like it was written by industry lobbyist to make the perceived importance of the four lower Snake Dams to farmers much greater than reality, without being technically incorrect. The second sentence needs to be changed to something like. Barges transport between 50 and 60 million tons of cargo each year on the CRS, with the lower Snake River beginning near Lewiston, Idaho, and Clarkston, Washington accounting for between X and Y million tons of this total. The third sentence should be deleted. Farmers would still be allowed to export crops to overseas markets no matter what alternative is selected.	The commenter correctly pointed out a unintentionally misleading statement in the Executive Summary. The Columbia-Snake River system, not solely the Snake River, carries 50 to 60 million tons of cargo each year. This has been corrected in the FEIS.
6544	11	srkiefer@cableone.net	N/A	It appears the October 19, 2018 Presidential Memorandum to shorten the timeline to prepare the EIS from 3 to 2 years was made for partisan political reasons to favor current industrial uses of the CRS. The decision to primarily compress the schedule between the draft EIS and the signing of the record of decision will result in the public and entities outside of the co-lead agencies having much less ability to affect the final EIS and help you produce one that is regionally accepted and actually balances the costs/benefits to the region, including recovering the fish.	This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period. In terms of recovery of salmon and steelhead, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
6544	12	srkiefer@cableone.net	N/A	There are several concerns with the discussion of water temperatures. It should be highlighted that increasing summertime water temperatures already dramatically increased migration mortality for Snake River sockeye in 2015, and these conditions are predicted to be more common and get worse. It should be highlighted that the summertime cold water releases from Dworshak would be much more effective with the breach alternative. The following statement is disappointing. There is also regional controversy over the role the federal projects may play in contributing to higher water temperatures. Once again by combining the temperature effects of the upstream storage projects and the mainstem run-of-river hydro projects, this draft EIS deflects and distracts from the fact that the mainstem run-of-river hydro projects results in more heating of water entering them by slowing the flow and creating more surface area than would occur with breach.	Regarding water temperatures under dam breach scenarios, our analysis of MO3, which includes breaching the four Snake River dams, shows that some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. The water temperature model used to analyze all EIS alternatives underwent review by experts outside of the co-lead agencies, including scientists from the US EPA, USGS, and Portland State University. In addition, the US EPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the lower Columbia River and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6544	13	srkiefer@cableone.net	N/A	Including the following section in the MO4 section without including it in the dam breach alternative section suggests bias and must be corrected. This analysis is based largely on existing technology and the regions existing resource portfolio. Future technology developmentssuch as advances in utility-scale storage, demand management, adding voltage support capabilities to wind or solar, other emerging renewable options like tidal or wave power, small modular nuclear reactors, pumped storage, and technologies not yet in the public eyemay reduce the need to rely on fossil-fuel power for integrating variable renewable resources.	The comment is implying that there is bias in the Executive Summary description of MO3 and MO4 because the MO4 section describes a list of renewable technologies. However, contrary to the comment, the statement that technological advances and other potential low-carbon power options may become available in the future is consistent with the description of MO3 emissions effects in the Executive Summary. In the Draft EIS, see page 27 of the Executive Summary. The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council (Council) in their Seventh Power Plan (page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. In the Draft EIS, see Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, page 3-821; and Appendix H, Power and Transmission, at Section 2.2. While the EIS specifically identified two portfolios, it evaluated all primary technologies from the Seventh Power Plan to identify the most cost-effective resources at improving regional reliability. After identifying the most cost-effective resources, the EIS analyzed two resource portfolios to replace the hydropower generation of the lower Snake River dams, both of which maintain regional power system reliability. One portfolio contains natural gas power and the other was a renewable portfolio of solar, storage and demand response. See Section 3.7.3.5, pages 3-904-910 of the Draft EIS.
6544	14	srkiefer@cableone.net	N/A	Many of the dire statements on the impacts to industrial users from breaching the four lower Snake Dams are clearly overstated, and some are just false. Some examples are as follows: 1) MO3 would not meet the objective to Provide a Reliable and Economic Power Supply. This statement is false. One option described is to replace the power from these dams with natural gas. If natural gas was selected, this would provide a more reliable power supply at similar costs to consumers. Private industry has added many times the average output from the lower Snake Dams in the past 20 years. If dam breach was selected, it would take several years to implement. If the co-lead agencies did nothing to replace this power, private industry would see the coming demand, and replace it at similar costs to consumers.	The commenter is correct that the EIS evaluated a natural gas replacement resource portfolio. The EIS also considered two financing scenarios, one in which Bonneville would finance the resources and another where financing would come from regional utilities. Under both of these scenarios, replacing the lost hydropower would increase costs compared to the No Action Alternative. See Section 3.7.3.5, at 3-918-924 of the Draft EIS; see also Table 3-166 of the Draft EIS. While the commenter is correct that private industry could build new power resources, many Bonneville customers acquire all or almost all of their power from Bonneville and the FCRPS as opposed to private industry and the open market.
6544	15	srkiefer@cableone.net	N/A	2) MO3 would more than double the regions risk of power shortages compared to the No Action Alternative. This statement is also false for the same two reasons as above. The co-lead agencies could develop a breach alternative with objectives to maintain or improve reliability at similar costs to consumers. Ideas could include combinations of the following; increased efforts to conserve power, short term storage of hydropower in batteries at night for use during daytime, long term storage as hydrogen produced by splitting water when excess hydropower or other renewable are available. Subsidize the development of regional powerplants that use methane produced in manure digesters at large CAFOs (dairies and feed lots). None of these ideas would increase green house gas emissions, and the manure digesters would actually reduce overall green house gas emissions.	The statement that MO3 would more than double the regions risk of power shortages compared to the No Action Alternative is consistent with the findings of the EIS before replacement resources are constructed. See Section 3.7.3.5, Effects on Power System Reliability, page 3-903; and Appendix H, Table 2-1 in the Draft EIS. The EIS analyzes potential replacement resources as described in Section 3.7.3.1. The comment suggests a variety of potential power resources that could support reliability and reduce emissions. The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council (Council) in their Seventh Power Plan (page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, page 3-821; and Appendix H, Power and Transmission, at Section 2.2 in the Draft EIS. Biogas technologies, such as the digesters mentioned in the comment, are not one of the primary resources identified by the Council, and were thus excluded. See Section 3.7.3.5, Potential Replacement Resources and Associated Costs, for additional details on the replacement resource portfolio identified for MO3.
6544	16	srkiefer@cableone.net	N/A	3) This statement appears to be overstated. the conventional, least-cost resource replacement would include 1,120 megawatts (MW) of combined cycle natural gas turbines at an overall cost of about $200 million a year. Private industry has developed more than 1,120 megawatts of natural gas turbines in the region over the past decade at similar costs to the consumers. Are you saying that since consumers would be paying similar amounts, but more to private industry instead of BPA, that it is a cost?	As described in Section 3.7.3.5 of the draft EIS, Potential Replacement Resources and Associated Costs, replacement resource costs would directly affect regional end-user power rates, regardless of whether Bonneville or public utilities themselves acquire replacement resources. See draft EIS, Section 3.7.3.5, at 3-918-924 and Table 3-166. The source of resource information used in the EIS, such as the cost of combined cycle natural gas power plants, is the Northwest Power and Conservation Council's 7th Power Plan and Mid-term update. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission at Section 2.2. Additional information on resource selection can be found in Appendix H and the specific costs of natural gas power plants can be found in Table 2-3 of Appendix H in the draft EIS.
6544	17	srkiefer@cableone.net	N/A	4) This statement is false: MO3 would also not meet the objective to Minimize GHG Emissions. While I believe this draft greatly overstates the costs, the preceding paragraphs describe how MO3 could be accomplished while meeting this objective. Considering how options would affect global warming is very important. However, this draft EIS is missing one important component in this consideration. That is, the impacts to carbon sequestration from alternatives that would result in wild salmon and steelhead recovery, maintaining wild populations as museum pieces, or causing them to go extinct.	Sections 3.7.3 and 3.8.3 of the Draft EIS consider two alternative replacement resource portfolios to replace lost power generation due to breaching the four lower Snake River dams under Multiple Objective Alternative 3 (MO3). One of these portfolios relies solely on building or acquiring renewable resources for replacement, finding that this scenario still results in some increase in greenhouse gas (GHG) emissions, for example due to the need to maintain reliability during periods when the renewable resources could not ramp up to meet power demand. With respect to the influence of salmon on carbon sequestration, Section 3.5 identifies that fish migration through the lower Snake River corridor would improve under MO3. Section 3.5.2.3 in the Draft EIS recognizes that anadromous fish deliver resources that affect food web productivity and influence flora and fauna across the Columbia River Basin. This indicates that, in some areas, MO3 would likely improve landscape carbon sequestration. However, in other areas, MO3 may reduce landscape carbon sequestration. As described in Section 3.6.3.5 in the Draft EIS, lower water levels in the spring and early summer in some areas under MO3 would reduce productivity in some existing emergent herbaceous and forested and scrub-shrub wetlands. The overall effect of MO3 on landscape level carbon sequestration across the Basin is uncertain.
6544	18	srkiefer@cableone.net	N/A	5) Of these two back-to-back statements; the first is overstated, and the second is false. there would be adverse impacts to irrigation in the lower Snake River borne by other public and private entities due to dam breaching. Assuming 47,926 acres were no longer irrigated. There are 14 agri-businesses that pump water from Ice Harbor pool. All that needs to be done is to extend their pipes and buy them larger pumps. This land will still be irrigated.	This EIS discusses engineering solutions (pipeline extensions for example) in Chapter 3.12 section 3.12.3 Environmental Consequences - Specifically under Region C under the MO3 alternative (see line page 3-1267 line 3244 in the Draft EIS) and in Appendix N. The report which this EIS draws upon, as discussed, concluded that modifying the existing pump system was cost prohibited. NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. However, the co-lead agencies do not have authority to provide mitigation for the effects to private infrastructure such as irrigation pump systems.
6544	19	srkiefer@cableone.net	N/A	6) The first sentence in the MO3 transportation section and many of the statements clearly overstate the effects. Major adverse effects would be anticipated under MO3. It appears that the draft EIS assumes that most of the commodities (primarily grain) that are transported in barges on the lower Snake River would still be transported through the Lewiston area. Grain grown in the interior US that is now transported in trucks on HW 12 to take advantage of the heavily subsidized barge system, would likely either use interstate 90 to Seattle, or travel shorter distances and be barged on the Mississippi system. Much of the grain grown regionally would be trucked shorter distances by the farmer to closer rail terminals instead of being trucked further to take advantage of the cheaper more subsidized barge system. Estimating increased highway maintenance costs without including increased gas tax revenue is biased.	The transportation optimization model utilized in the EIS evaluates how trade flows would be expected to change with loss of barge transportation. The uniqueness of the wheat in eastern Washington and its Asian markets, means that little shifting to midwest barge transportation and markets will occur. Increases in truck trips as well as increases in road infrastructure costs are included in Section 3.10.3.5. The marginal increase in gas tax receipts that may accompany this increase has been added to this Section.
6544	20	srkiefer@cableone.net	N/A	7) This statement is overstated and likely false. Adverse regional economic effects would occur If you compare the economic growth of the Lewiston/Clarkston area over the past 70 years to similar sized communities 70 years ago, it appears that the four lower Snake Dams have actually depressed the economy of the area. Future economic growth will occur by people who can build and work were they want to live, and more people will want to live in the area with a free flowing Snake River and abundant salmon and steelhead, than with barge ports and at best occasional limited fisheries for hatchery fish.	It is not clear what statement the commenter is referring to in particular. However, The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
6544	21	srkiefer@cableone.net	N/A	8) The following statement is false. For water quality, water temperatures would be warmer in the summer. The cold water releases from Dworshak will be more effective at cooling the Snake River all the way down to the Columbia with a natural river as compared to current conditions where it is warmed up more as it spread out and slowed down as it moves through the reservoirs. With Dworshak operated the same as in the preferred alternative, how much longer would it take the cool water at the confluence of the Snake and Clearwater rivers to reach the Columbia, how much more would it heat up by the time it gets there? I disagree that the preferred alternative protects valuable fish and wildlife resources. As I have stated earlier, I believe the CSS model estimates of 35 to 28 percent increases in SARs from only modest decreases in average powerhouse passage rates are likely too high. Even with these estimated increases in SARs I believe are too high, given the likely range and variability of ocean productivity, wild Snake River stream type Chinook, sockeye, and steelhead would still be in jeopardy of extinction.	The water temperature analysis specific to MO3 (the dam breaching scenario) utilized the Dworshak CE-QUAL W2 (2-dimensional model) and the lower Snake River HEC-RAS (1-demesional models) to predict water temperatures under a dam breach scenario, while incorporating operations at Dworshak Dam for downstream water temperature management. No Action Dworshak operations were used in the MO3 analysis. Results were provided to the fish team for incorporation into COMPASS and CSS modeling and other analysis to evaluate the impacts to anadromous fish. Future dam breaching analysis may provide an opportunity to investigate Dworshak Dam operations further, but this would need to occur outside of the EIS process and under a more appropriate study framework. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. Regarding the CSS model statement, the co-lead agencies used current high quality information and the best available science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The average outcome for salmon and steelhead is expected to be positive based on CSS analysis.
6547	1	clopresti@owt.com	N/A	It's better to clean up Puget Sound first, in my opinion, before breaching the Lower Snake River Dams.	Thank you for your comment. Cleaning up Puget Sound is outside the scope of this EIS, which focuses on CRS operations, maintenance and configuration. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
6550	1	N/A	N/A	The DEIS does not acknowledge the importance of the Columbia basin salmon to the Southern Resident Killer whales, whose very survival depend on the healthy Chinook salmon runs and fails to mention the SRKW in their executive summary. These whales need to be able to access salmon from different river systems at different times in order to survive and they rely heavily on the Columbia River during their time on the outer coast which is up to 6 months of the year, Columbia Spring Chinook being of particular importance.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
6554	2	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	While the co-lead federal agencies present a well-defined preferred alternative, PPC remains concerned about the additional costs and biological uncertainty that this preferred alternative may engender. Going forward, close monitoring and adaptive management will be required. We will need certainty and clarity about co-lead agency mileposts and transparency regarding actual performance of the preferred alternative against co-lead agency stated objectives. Solutions will have to be found to ensure that preference customers do not solely bear incremental costs that provide broader social and environmental benefits.	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the biological models and will help to determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored, as will the effects to generating resources around the basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. In developing a Preferred Alternative, the co-lead agencies considered the need for an adequate, efficient, economical and reliable power supply, combined with the need to meet other authorized CRS purposes. The agencies additionally committed to mitigating for impacts to fish and wildlife impacted by CRS operations, maintenance and configuration. The financial responsibility for the costs of the measures included in the Preferred Alternative is not solely allocated to Bonneville's power ratepayers. Fish mitigation costs are assigned to each authorized project purpose based on each purposes overall share of project costs, as determined by an established cost allocation, and this allocation is recovered through power rates. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Congress also granted Bonneville discretion to fund the power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992, in some situations, including the Columbia River Fish Mitigation program. (Energy Policy Act of 1992, Pub. L. No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)). Additionally, as described in Section 3.19 of the EIS and Appendix Q, funding to operate the system comes through multiple mechanisms, including Federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. For joint related costs, including funding for fish and wildlife mitigation actions, the Corps and Reclamation receive annual congressional appropriations to fund most, if not all, capital investments. Bonneville reimburses the U.S. Treasury for the power share of these appropriations. Once the investment is in place, Bonneville will typically direct fund the power share of the operations and maintenance costs associated with the facility. In addition to congressional appropriations for fish and wildlife and costs directly funded to Corps and Reclamation by Bonneville, the Bonneville Fish and Wildlife Program (which is separate and distinct from direct funding described above) funds hundreds of projects each year to mitigate the impacts of the Federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the Federal Columbia River Power System (FCRPS). Bonneville uses its authority under 16 U.S.C. 839b(h)(10)(A), to make expenditures to implement its Fish and Wildlife Program. These expenditures provide system-wide funding for actions that also mitigate for the non-power purposes of the CRS, so Bonneville recoups the non-power share of those expenditures from the U.S. Treasury as credit, as required under 16 U.S.C. 839b(h)(10)(C). Bonneville's Fish and Wildlife Program expenditures incurred mitigating the CRS operations identified in the Final EIS and adopted in Bonneville's Mitigation Action Plan would continue to be allocated and borne as provided by existing laws governing the FCRPS and the long-standing accounting procedures used to implement them.
6554	3	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	With the completion of the Final EIS, a follow-on public process should be established by BPA or the co-lead agencies, as appropriate, to periodically share specific performance outcomes of the preferred alternative. If necessary, from that process, BPA or the co-lead agencies should create engagement opportunities for any significant adaptive management steps that are needed to better align system performance to the preferred alternative objectives.	Thank you for your comment. The co-lead agencies plan on continuing stakeholder involvement through the various regional forums and public outreach. As mentioned in the Appendix R, Part 1, there is robust, ongoing monitoring and adaptive management for eh Preferred Alternative. In Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS,co-lead agencies would publish annual report of implementation activities, stakeholder participation, and management review findings.
6554	4	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	The primary focus of Northwest public power is assuring that any new costs resulting from the governments process are equitably allocated and not borne exclusively by BPAs public power customers. To the extent the preferred alternative results in additional costs allocated entirely to public power, it is time to find ways to build on existing federal law to more broadly share these regional costs. Not only is it appropriate to equitably align cost responsibility with public benefits but doing so also recognizes the regions shared stake in both fish recovery and the financial health of BPA.	The financial responsibility for the costs of all of the measures included in the Preferred Alternative is not solely allocated to Bonneville's power ratepayers. Fish mitigation costs are assigned to each authorized project purpose based on each purposes overall share of project costs, as determined by an established cost allocation, and this allocation is recovered through power rates. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Congress also granted Bonneville discretion to fund the power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992, in some situations, including the Columbia River Fish Mitigation program. (Energy Policy Act of 1992, Pub. L. No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)). Additionally, as described in Section 3.19 of the EIS and Appendix Q, funding to operate the system comes through multiple mechanisms, including Federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. For joint related costs, including funding for fish and wildlife mitigation actions, the Corps and Reclamation receive annual congressional appropriations to fund most, if not all, capital investments. Bonneville reimburses the U.S. Treasury for the power share of these appropriations. Once the investment is in place, Bonneville will typically direct fund the power share of the operations and maintenance costs associated with the facility. In addition to congressional appropriations for fish and wildlife and costs directly funded to Corps and Reclamation by Bonneville, the Bonneville Fish and Wildlife Program (which is separate and distinct from direct funding described above) funds hundreds of projects each year to mitigate the impacts of the Federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the Federal Columbia River Power System (FCRPS). Bonneville uses its authority under 16 U.S.C. 839b(h)(10)(A), to make expenditures to implement its Fish and Wildlife Program. These expenditures provide system-wide funding for actions that also mitigate for the non-power purposes of the CRS, so Bonneville recoups the non-power share of those expenditures from the U.S. Treasury as credit, as required under 16 U.S.C. 839b(h)(10)(C). Bonneville's Fish and Wildlife Program expenditures incurred mitigating the CRS operations identified in the Final EIS and adopted in Bonneville's Mitigation Action Plan would continue to be allocated and borne as provided by existing laws governing the FCRPS and the long-standing accounting procedures used to implement them.
6554	5	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	The economic, environmental, and operational benefits of the Federal Columbia River Power System (FCRPS) as it exists today should be properly considered and accounted for. Hydropower is a 24/7 clean renewable source that is vital to meeting the regions carbon goals, which continue to strengthen as societys concerns about carbon intensify. A recent study published in the Proceedings of the National Academy of Sciences (PNAS) concluded that among the countrys 20 largest electric regions, the BPA hydropower-based system resulted in the Pacific Northwest region producing and using the cleanest energy in the nation. FCRPS hydropower is also a flexible resource that enables the region to meet future sustainability goals by integrating intermittent renewable resources like wind and solar onto the grid. The flexible capacity that the FCRPS provides will only increase in demand and value as state legislation, policies and economic or other factors drive the retirement of fossil-fueled base load resources and replace them with intermittent renewable generation. The FCRPS projects are a key part of reliable and affordable grid operations and cannot be replaced at low cost by intermittent renewable resources. The value of capacity and reliability of the power produced by these projects has to be properly accounted for.	The comment makes multiple statements regarding the benefits of regional hydropower for clean energy goals and power system reliability. The statements are largely consistent with the findings and discussions in the EIS such as the role of hydropower in greenhouse gas emissions, integrating renewables, and the flexibility of hydropower. The statement that the regional power sector is relatively clean compared to other regions of the country is also consistent with the EIS. See draft EIS, Table 3-199 at page 3-977. While the EIS uses the resource cost information from the Northwest Power and Conservation Council to estimate the potential range in costs of replacement resources, this does not cover all of the characteristics of the four lower Snake River dams. As described in Section 3.7.3.5 of the EIS, for the Lower Snake River Full Replacement, Bonneville used BP-20 to assess the value of flexibility. The EIS acknowledges that there would be more demand for generation flexibility and the ability to carry reserves in the power system as coal plants retire and flexible resources are needed to integrate new variable renewable resources. As a consequence of the increase in demand for flexibility to provide reserves, the value of this capability is likely to increase. The EIS partially reflects the costs of acquiring this additional flexibility in the rate sensitivity analysis. For additional information, see the Integration Services sensitivity (reflecting the cost of additional balancing reserves needed to integrate replacement renewable resources) and the Ramping and Flexibility sensitivity (reflecting the cost of additional ramping and sustained peaking capacity needed in Multiple Objective Alternative 3) in Section 3.7.3.1 of the EIS.
6554	6	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	As community-owned, non-profit entities, public power utilities are particularly mindful of their public service mission and obligations to all people they serve. Public power utilities serve many individuals and communities that are struggling. In both urban and rural locations, public power utilities fund substantial low-income assistance programs. In our modern economy, electricity has become an essential public service. We need to be mindful that policy changes that adversely impact the hydro system will result in higher costs for the regions ratepayers, which puts some urban and rural ratepayers at a higher risk that they wont have access to this essential public service.	The comment that increases in utility costs can adversely affect vulnerable groups is consistent with discussions in the EIS. The wholesale power rate effects described in the comment are consistent with the findings of the EIS. The EIS recognizes concerns around the affordability of electricity. The Environmental Justice analysis (Section 3.18.3 and Section 7 of the EIS) provides further detail on this as well as the potential disproportionate effects to tribal, low-income and minority populations. The EIS also discusses that Bonneville customers, such as the public utilities mentioned in the comment, may have larger increases in rate pressures than other regional utilities that do not purchase power directly from Bonneville. See draft EIS, Section 3.7.3.5, Residential Effects at page 3-929. Chapter 5 and Exhibit 1 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as for urban and rural utility customers.
6554	7	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	The energy landscape and outlook in the West has evolved rapidly since 2017. Recent work by the Northwest Power Pool (NWPP) and NWPCC has highlighted growing resource adequacy issues in the region due in large part to the accelerated retirement of numerous coal resources. By the metrics of the NWPCCs most recent Power Supply Adequacy Assessment, the regions power supply may start to become inadequate by 2021. Without action, the chances of reliability events or blackouts increases alarmingly over the following five years. This concern about future resource adequacy is a consensus among regional utilities and experts. Utilities of all types have begun serious efforts through the NWPP to invest in new analytical capabilities and to find tangible and reliable solutions. Given these factors, the financial and rate impacts from the Base Case scenarios in the D-EIS are extremely conservative. Specifically, based on known regional resource retirements, any significant lost hydro capability from alternative FCRPS operations would need to be replaced in its entirety with new resources. At the same time, Oregon and Washington are advancing environmental policies that may make construction of new thermal generating resources difficult or impossible. These operational and policy realities need to be carefully considered, as they impact overall regional electric grid reliability and resource adequacy beyond that served by the FCRPS. As such, for the final EIS it is essential that cost impacts including expected coal retirements and replacement of lost hydro capability with new carbon free resources are the primary basis for comparison of the alternatives. The analysis in the D-EIS shows conclusively that degradation of the hydro system as contemplated in MO3 and MO4 would realistically cost the region up to $1 billion per year or result in substantial increases in GHG emissions. Highlighting this information in the final EIS is crucial for policymakers and the public in adequately understanding the substantial tradeoffs. PPC strongly supports carrying forward the analytical framework from the D-EIS to the final with further emphasis on the costs of fully replacing lost hydro capability. In addition, PPC would support additional information or analysis that can be provided to address erroneous and unsupported statements by certain stakeholders that the output of the Lower Snake River projects is surplus to BPA or regional needs, or is somehow being sold at a loss.	The EIS acknowledges that the energy sector is constantly undergoing transformation. The commenters statement that planned additional coal power retirements would decrease power reliability in the region is consistent with the findings in the EIS. Existing coal projects were presumed to be online when developing the No Action Alternative. See draft EIS, Section 3.7.3.1, Base Case Methodology and Cost Sensitivity Analysis at page 3-816 and at 3-823. Since development of the base case analysis of the Draft EIS, additional coal retirements have been announced. To address this concern, the EIS considered various sensitivity analyses as well as examined two potential coal retirement scenarios. See draft EIS, Section 3.7.3.1, Availability of Coal Resources at pages 3-841-842 and, Section 3.7.3.2, Table 3-123. The statement that replacement resource costs could be up to $1 billion per year is consistent with the findings of the EIS, and the rate sensitivities estimate the potential regional cost pressures from carbon compliance and coal retirements under Multiple Objective (MO) Alternative 3 and MO4. See draft EIS, Table 3-166 and Table 3-182. Consistent with the recommendations in the comment, the EIS also acknowledges that, given recent energy policy, carbon-free resources are the more likely replacement resource portfolio. See draft EIS at line 29666 at page 3-988.
6554	8	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	PPC also requests that the final EIS include more information on the availability of incremental energy efficiency. We have observed that certain stakeholders mistakenly assert that the lost hydropower generation could easily or inexpensively be replaced with energy efficiency when, in fact, BPA and regional utilities are already pursuing all cost- effective measures. PPC requests that the final EIS include additional output from GENESYS describing expected unserved energy from modeled reliability impacts. Finally, any additional information or analysis regarding the secondary environmental impacts of the renewable portfolios would be helpful. This could include factors such as land use, avian impacts, service life of equipment, and required input resources such as minerals or metal.	Based on responses to public comments, the final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. (See Section 3.7.3.1 and Chapter 2 of Appendix H). The EIS power analysis included all cost-effective conservation identified by the Northwest Power and Conservation Council (Council) in the load forecasts analyzed in the power analysis (Section 3.7). All cost effective conservation in the region is assumed to be acquired consistent with existing law and mandates regardless of the status of the four lower Snake River dams. The Councils estimated available efficiency gain projection is not a potential replacement resource for the lost capability from the four lower Snake River dams. The EIS also includes a short description of why additional conservation is not assumed as a potential replacement resource even in the alternative where power prices are likely to increase. To maintain regional reliability at the No Action Alternative levels, other types of replacement resources are needed. Appendix H, Section 2.2 of the Final EIS provides additional details regarding energy efficiency and the selection of replacement resources. The EIS analyzed Conditional Value at Risk (CVaR), which evaluates the amount of monthly average energy not served in the worst 5 percent of Loss of Load Probability (LOLP) simulations. Chapter 4 of Appendix J summarizes the CVaR results. The EIS did not analyze expected unserved energy (EUSE), which is similar to CVaR. EUSE is the average energy not served averaged over all of the LOLP simulations. Thus CVaR focuses on the years with the largest impacts. Regarding other impacts from replacement resource portfolios, the EIS discusses the potential land use of solar replacement resources and the potential for impacts on natural and cultural resources (e.g., Multiple Objective Alternative 3 discussion at line 27296 at page 3-904 of the draft EIS). The EIS also acknowledges that any acquisition of resources would require additional site-specific environmental compliance, including NEPA analyses, permitting, and a potential statutory process to allow

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Bonneville to acquire resources. In response to this and other public comments, Chapter 2, Section 2.2.4 in Appendix H of the Final EIS includes a more detailed description of the process and timeline for acquiring new resources. This section includes a discussion of the environmental review process associated with new resources and acknowledges potential environmental impacts associated with new renewable generation as mentioned in the comment.
6554	9	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	Opportunity for Comment and Public Engagement The co-lead agencies have invested substantial resources to produce a comprehensive analysis in combination with understandable narrative at different levels of expertise and subject matter knowledge. This includes an accessible Executive Summary providing an overview as well as much more in depth analytical chapters and appendices. The initial scoping process was robust and resulted in a reasonable range of alternatives. This includes a comprehensive analysis of dam breaching, higher spill levels, and operations that increase hydropower generation. It would be infeasible to examine the infinite possible changes to CRS operations and structures, and the D-EIS provides sufficient analysis for decision-makers to understand the relative trade-offs of different alternatives and to make informed decisions. It is important to balance the need to make the D-EIS broadly available to the public and take public comment with the need to keep the NEPA process moving and prepare a final EIS that considers public comment. It is also crucial that the system operates pursuant to legally valid NEPA and Endangered Species Act (ESA) coverage. In balancing these obligations, the 45-day comment period that was noticed well in advance is adequate to provide meaningful feedback on the D-EIS analysis, especially when combined with other methods of participation. The plan for six public comment meetings was robust and provided opportunity for broad public participation. The move to teleconference in response to the COVID-19 crisis was prudent and actually increased accessibility. This was evidenced by the hundreds of verbal comments received from a wide range of organizations, demographics and interests. Additionally, there was adequate time available during the teleconferences for participants to provide multiple comments if desired.	Thank you for your comment.
6554	10	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	Power Generation and Transmission Analysis Accurate and comprehensive analysis of the power generation and transmission impacts of the alternatives is essential for public power customers and the region as a whole. The FCRPS is the backbone of the regional power system and provides its largest source of carbon free energy, capacity and flexibility. A reliable, affordable, and clean power supply is fundamental to the Northwest economy as well as to the health and safety of its residents. Meaningful analysis of operational alternatives requires understanding the differences in the energy, capacity, and flexibility that the FCRPS can provide. Reductions in capability must either be met with the redispatch of existing resources in the region or addressed through imports outside the region. The analytical choice of studying both thermal and new renewable resource portfolios provides meaningful information on the range of choices and costs of replacement resources. Further, the renewable resource portfolios based on the optimization of the Northwest Power Planning and Conservation Councils (NWPCC) 7th Power Plan represents a reasonable approach, including a diversified mix of wind, solar, and battery storage. There is no compelling reason to believe that a different mix or re-optimization would have a meaningful impact on outputs. The framework for Power Generation and Transmission analysis is robust and utilizes broadly accepted tools and inputs that have been thoroughly vetted in the region. Key tools include Hydsim for hydro generation, GENESYS for reliability, AURORAxmp for regional production costs, Gridview for transmission reliability, and the BPA Rates Analysis Model for wholesale power rate impacts. Inputs for demand and resource costs are reasonable. PPC also supports the range of metrics used to evaluate the economic and financial impacts of alternative operations. These outputs provide meaningful information on electricity rate impacts and a variety of views on the social, financial, and economic effects of changes to power and transmission resulting from alternative operations.	The comments about the importance of the Federal Columbia River Power System for regional power reliability and carbon emissions are consistent with the EIS findings. The statement that the EIS analyzed two resource portfolios to replace the hydropower generation, both of which maintain regional power system reliability, is also consistent with the methodology of the EIS. The discussion of the power analysis framework and the comment that the power analysis used a variety of industry standard models and considered a range of metrics is also consistent with the methodology of the power analysis. See EIS, Section 3.7.3.1, Methodology.
6554	11	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	Preferred Alternative Spill Levels are Untested and Need to be Monitored Despite the lack of evidence showing benefits to fish from increased spill, the Preferred Alternative continues to incorporate higher spill levels to improve SARs. Increasing spill to 125% of the Total Dissolved Gas (TDG) standard, as the Preferred Alternative suggests doing, may in fact harm the species it is meant to help. This level of TDG represents uncharted territory in the CRS, and it exceeds the recommendations set by the EPA. In trying to help juvenile salmon, spill may result in compromising resident fish, other river organisms, and salmon through Gas Bubble Trauma (GBT). In addition to GBT, spill operations can delay adult migration back upstream, harming the very fish the operations are most intended to assist. This outcome must be prevented. For these reasons, the D-EIS includes provisions to monitor for unintended consequences of the preferred alternative and adapt operations as needed. The D-EIS Monitoring and Adaptive Management Plan (MAMP) outlines an approach to accomplish this. PPC is supportive of the MAMP and believes that it is a central pillar to the EIS and future operations. The MAMPs inclusion of specific metrics, as well as a commitment by the federal agencies to a transparent and scientifically robust management process that incorporates new information as it becomes available will help to avoid the worst unintended consequences of spill. These metrics, as with other aspects of the MAMP, should continue to be updated as the action agencies gain more information about the effects of spill and other changes to system operations that are selected as part of the preferred alternative. It is essential that monitoring for GBT include adequate sample sizes that accurately represent the typical TDG exposure of juvenile fish populations. The commitment expressed by the federal agencies in the quote below, excerpted from the MAMP, is critical. From the D-EIS, Appendix R-6-1 lines 336-341: In coordination with sovereign parties with interests in CRS spill operations, the FSWG will design a long-term study plan to assess the impacts of high spill on latent mortality on Columbia and Snake River salmon and steelhead. The study will need to address the following criteria: Statistically meaningful results Within a reasonable timeframe While providing safe fish passage These principles can result in robust management and analysis that benefit salmon and other species. However, there is some ambiguity to them by design, as each criterion is open to discussion and interpretation as part of the adaptive management plan. Reasonable timeframe, statistically meaningful, and safe fish passage are not commonly agreed upon metrics, as stakeholders with different perspectives have different goals for these elements. PPC expects that discussions and decisions around these matters will be transparent, and that there will be clear logic behind the choices that are made and opportunities for stakeholder input through a structured process. For these reasons, while the MAMP and principles above are a good starting point, they will only be useful if they can be successfully executed. This requires that the co-lead agencies have the flexibility under the final EIS to adaptively implement the management plan and to regularly and broadly share progress against stated objectives. Governance processes must also include clear records of the benefits or outcomes that are prioritized and explanations of why.	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted in the comment, there is considerable uncertainty in the effects; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. This will include additional monitoring for the effects of exposure to elevated TDG and will be developed with regional input to ensure adequate monitoring is in place for various lifestages of salmonids, as well as monitoring of non-salmonid species. As described in Appendix R, the co-lead agencies will implement the adaptive management framework utilizing the expertise of regional stakeholders within the context of the existing Regional Forum framework (e.g. RIOG, TMT, FPOM, etc). Results from implementation and biological studies will be discussed in public forums such as TMT and will also be posted on federal websites such as salmonrecovery.gov or similar sites. Existing governance processes will be maintained as federal agencies cannot delegate decision making authority for their authorized purposes.
6554	12	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	CSS and LCM Models Must be Calibrated and Validated PPC has significant concerns not only with the unintended consequences of increased spill, but also with the scientific and analytical approach used to arrive at those spill recommendations. The D-EIS Preferred Alternative and flex spill operations are primarily supported on the outcome of the Fish Passage Centers (FPS) Comparative Survival Study (CSS) model. While the D-EIS includes both the CSS model and NOAAs Life Cycle Assessment (LCM) model, the operations it proposes reflect benefits to anadromous fish predicted by the CSS model and not by the LCM model. Despite showing relatively similar results for in-river survival, powerhouse encounters, and other juvenile metrics for Snake River Spring Chinook, the two models diverge on expected smolt to adult returns (SARs). For MO4 and the Preferred Alternative, the CSS model predicts higher SARs than the No-Action Alternative, whereas the LCM model predicts lower returns than the No-Action Alternative. This is not just a matter of degree, but a directional contradiction. The models also do not agree on a starting point. They predict different returns from each other for the No-Action Alternative, which is the baseline against which all other results are compared. The models need to reflect reality before they can be trusted to estimate future conditions. The CSS and LCM models should be validated and calibrated to historical data to show that they can be relied upon to serve as inputs for the Final EIS. If the models cannot be shown to reflect historical SARs given historical conditions and hydro operations, they may not be useful in predicting future outcomes. This validation process should be inclusive of the co-lead agencies and provide for rigorous peer review and public distribution of results.	All models used for decision making in this EIS process have been peer-reviewed using the Corps of Engineers' Independent External Peer Review Process (IEPR). In addition to the IEPR process, the CSS models are reviewed annually by the Northwest Power and Conservation Council's Independent Science Advisory Board (ISAB). The COMPASS and LCM models were also recently reviewed by the ISAB. The co-lead agencies acknowldge the uncertainty reflected in the different predictions from the biological models and intend to reduce that uncertainty through a robust adaptive management plan. The co-lead agencies made the decision to present results from both sets of models for the final evaluation, along with descriptions of methods. All models must make assumptions which led to the use of both modeling approaches. The NOAA Compass/LCM models and the CSS models use different statistical approaches and input variables. Both are able to provide a good fit to recent survival, and travel time estimates, but the models do have substantially contrasting forecasts for these metrics under hypothetical scenarios of hydrosystem operation with respect to flow and spill.
6554	13	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	CSS Model Hypothesis May be Flawed In addition to calibrating the models, PPC believes that the CSS model may be based upon a flawed premise (the damage hypothesis), and that its results must be interpreted with caution. The CSS model is based on the observation that fish which pass through bypass systems have historically had lower adult return rates than fish which pass over dam spillways. The CSS model then hypothesizes that this is due to some unexplained harm to juvenile fish by dam turbines or bypass systems that results in latent mortality. It then concludes that in order to increase adults returns, fish must be passed over spillways, rather than through alternate routes, to increase SARs rates. The damage hypothesis ignores other potential explanations for the difference in SARs for fish that pass over the spillway versus through bypass systems. In fact, recent studies by National Marine Fisheries Services scientists have shown that the differences in SARs for different dam passage routes are better explained by how fish select those passage routes, rather than on any harm the routes cause. Faulkner, Bellerud, Widener and Zabel (2019)14 demonstrated that larger fish tend to follow spillways and smaller fish tend to pass through turbines or bypass systems. This result points to a new hypothesis for differential rates of juvenile fish survival and SARs. In comparing the potential hypotheses, the study found that fish size, rather than dam passage route, resulted in a better prediction of adult returns. Larger fish, regardless of passage, tended to have higher SARs than smaller fish. Adding fish size to the model resulted in improvements to several key indicators of statistical significance and model performance, whereas including passage routes did not provide the same improvements to the model. By including juvenile salmonid passage routes in its modeling and not fish size, the CSS model mistakes correlation with causation and provides information that is misleading and results in suboptimal operations for both fish and power. The Northwest Power and	All models used for decision making in this EIS process including the CSS model have been peer-reviewed using the Corps of Engineers' Independent External Peer Review Process (IEPR). In addition to the IEPR process, the CSS models are reviewed annually by the Northwest Power and Conservation Council's Independent Science Advisory Board (ISAB). As the comment notes, fish size may be an important variable in predicting eventual adult returns. The co-lead agencies referenced the Faulkner et al. paper as did the ISAB in their most recent review. Fish size will be a variable that the co-lead agencies will continue to monitor and follow as the science around latent mortality continues to evolve during the implementation of the Preferred Alternative.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Conservation Council has recommended annually since 2007 that the FPS add fish size to the CSS model. Until fish size is incorporated into the CSS, the model should be interpreted with extreme caution and recognized as not reflective of the best available science.	
6554	14	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	CSS and LCM Model Analysis As discussed above, the D-EIS MAMP includes metrics and processes to determine whether spill and other operational changes are having unintended consequences. However, the MAMP does not thoroughly outline how to address the disparities between the two competing salmonid life cycle models. Due to their prominence in determining CRS operations and structural changes, the CSS and LCM models both need to be included for assessment as part of the MAMP. This model-vetting process should include best available science, any new information or data, and be subject to peer review and open to public disclosure. Examples of criteria that could be included in this vetting are: 1) Does the model incorporate any variables or inputs that are not proven to be statistically significant? 2) Does the model exclude any variables or inputs that are shown to be statistically significant? 3) Does the model accurately reflect and predict (within an agreed-upon range) SARs given historical data? As the action agencies carry out the Preferred Alternative and MAMP, they will need to continually assess whether the operations and structural changes that have been enacted are having the desired effect. Further, assessment is required to determine if the models and other decision-informing documents support and lead to actions that improve outcomes for fish. Without a clear methodology to critically assess the CSS and LCM models, changes in juvenile and adult survival rates may be conflated with incorrect assumptions and result in the use of a model that does not accurately reflect impacts of changes in the CRS. This could lead to poor decisions regarding CRS operations well into the future. If the CSS or LCM models are shown to contain assumptions or inputs that do not hold up to scientific or statistical review, or if new information comes to light that calls into question their validity, the operational or structural changes made due to that models results should be brought before the Regional Implementation Oversight Group for review. PPC expects that this information would be made publicly available, and that the federal action agencies would make corrections to their operations, such as halting practices that were recommended by a model that has been found to have material flaws.	The framework for the adaptive management process is detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team and disputes will be elevated to the Regional Implementation Oversight Group (RIOG) as warranted. The co-lead agencies intend to continue with current practices of posting material on publicly available forums such as agency websites, salmonrecovery.gov, and/or in open public meetings such as TMT.
6554	15	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	Predation Management Avian, piscine and pinniped predation are among the largest individual contributors to salmon and steelhead mortality in the CRS. However, there is substantial public misperception of this, with many citizens attributing the majority of juvenile salmonid mortality directly to the FCRPS. PPC requests that the federal agencies quantify major sources of juvenile production and major sources of mortality as an important underpinning to the regional discussion and in recognition that the D-EIS has invested substantial time to discussing juvenile salmon impacts. This information will help to inform the regional dialogue on the impacts of the federal hydro system and potentially direct resources to priority areas of impact, such as predation management. Measures to reduce predation have had positive impacts on juvenile and adult fish survival in the past and will in the future, as well. These measures often represent some of the more cost-effective steps that the federal agencies can take. In the case of pinnipeds, reducing predation of adult salmonids produces a significant benefit, as these returning fish represent a small fraction of the outgoing juvenile population. For juvenile predation, the proposed John Day reservoir level modifications represent an action that has limited risk or downside and can significantly reduce Caspian tern nesting habitat. This is a good example of a measure that could provide cost-effective, measurable and a positive overall impact to fish populations. PPC supports further investigation of potential predation management techniques, and views these as an essential piece of any successful salmonid mitigation program.	Thank you for your comment. The co-lead agencies do currently investigate and quantify major sources of juvenile production and major sources of mortality. The co-lead agencies appreciate your support for further investigation of potential predation management techniques.
6554	16	mdeen@ppcpdx.org; Scott Simms	Public Power Council; Public Power Council PPC	Other Socioeconomic Impacts Although PPC is organizationally focused on impacts to hydropower, fish and wildlife, we clearly recognize there are other socioeconomic impacts of potential changes to the configuration and operation of the CRS. The D-EIS has appropriately included analysis of a range of impacts to air quality, flood risk, navigation and transportation, recreation, and water supply. These impacts are essential to consider for multi-purpose projects. PPC encourages the federal agencies to carefully consider the comments of our PPC member public power utilities, as well as those provided by the Pacific Northwest Waterways Association and Northwest RiverPartners, for ways in which these areas of analysis can be enhanced in the final EIS.	Thank you for your comment. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The co-lead agencies have worked diligently to address all comments received and update the EIS as appropriate based upon high quality available information. Please refer to Appendix T for the comments received and subsequent responses.
6558	1	markleed02@gmail.com	N/A	The elevation of spawning habitat in the Snake Basin ensures that cold water will be maintained in the face of climate change. The preferred alternative doesn't provide reasonable assurance that it can avoid fish extinction or that it will meet requirements of the endangered species act. Hatchery production is not a viable strategy for the long term. Fish ladders that exist at the dams are fragile and prone to disruption; they cannot be relied upon to reasonable support fish passage.	Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy. Hatchery programs have long been a part of the approach for salmon recovery. Under this alternative, hatchery programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery operations are proposed. The listings of ESUs/DPSs often include fish produced in hatcheries. Hatchery origin fish are very important to Tribal and sport harvest in within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the three co-lead agencies have legal requirement to produce hatchery fish as mitigation for components of the CRS. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act. Regarding fish passage, the four lower Snake River and four lower Columbia River dams are equipped with adult fish ladders which are safe and effective and reliable for passing adult fish upstream, and adult salmon and steelhead passage is generally considered good through the lower Snake and Columbia rivers. For example, adult survival rates (adjusted to account for reported harvest and typical straying rates) for SR spring/summer Chinook salmon are relatively high, averaging about 89 percent between Bonneville and McNary Dams and 83 percent between Bonneville and Lower Granite Dams). These survival rates include "natural" mortality as well as any mortality associated with injuries incurred from predators.
6559	1	parrishantonia@gmail.com	N/A	Below, I have explained the logic behind dam removal and the shortcomings of the EIS. 1. The negative impact of the Lower Snake River Dams (LSRDs) on Salmon (specifically Coho and Chinook) and Steelhead abundance is listed, but instead of illuminating breaching as a feasible solution, the EIS details forms of mitigation such as improved infrastructure and hatcheries. While fish ladders and spillways do aid Salmon to a small extent, this is an unnatural environment for the fish and the dam stands as an almost impenetrable barrier for spawning fish returning from the sea. Hatcheries are an insufficient form of mitigation as they replace wild Salmon with inbred, poorly adapted Salmon that increase the population of non-wild fishes through natural selection. Salmon and other wild fishes also require moving water in order to reach the ocean or spawning basin and the reservoirs created by dams slow and confuse them. Reservoirs also cause increased water temperature which is harmful to fish. Retaining these LSRDs risks extinction of the very species that the Endangered Species Act seeks to restore. Additionally, in order to maintain trust with native tribes, the fish must be restored to this ecosystem.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Hatchery origin fish are very important to Tribal and sport harvest in within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. The listings of ESUs/DPSs often include fish produced in hatcheries. Further, the three co-lead agencies have a legal requirement to produce hatchery fish as mitigation for components of the CRS. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act.
6559	2	parrishantonia@gmail.com	N/A	2. The EIS reports that these dams are a tremendous source of clean and renewable energy for the communities in the Columbia River Basin. One objective of the CRSO is to minimize greenhouse gas (GHG) emissions. Unfortunately, it is difficult to characterize dams as clean when they release large amounts of methane which is one of the most potent greenhouse gasses. The creation of reservoirs causes build-up of sediments and accumulation of nitrate in stagnant waters and this excess of nutrients leads to algal blooms which release methane when they decompose. This means that there is a negative tradeoff for retaining dams in regard to energy. The production and emission of methane should be considered in the EIS GHG analysis.	The EIS evaluates the research pertaining to methane emissions from hydropower reservoirs. Appendix G, Chapter 5 of the EIS details the assessment of reservoir methane emissions from the CRS projects. The findings are summarized in Section 3.8. This assessment finds that reservoir characteristics and management substantially influence methane emissions. A 2016 study developed by the Corps' Walla Walla District concluded that for the relatively clean reservoirs of the Federal Columbia River Power System, which include the lower Snake River dams, conditions for low dissolved oxygen concentrations are not prevalent; thus methane gas is generally not an issue. Additionally, in 2017, the Northwest Power and Conservation Council found that data on these sites were insufficient to estimate the reservoir methane emissions specifically for the Columbia River System, but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies would allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams.
6559	3	parrishantonia@gmail.com	N/A	3. According to the EIS, a dam is necessary for controlling floods to maintain communities on riverbanks. This is not an issue that should be controlled. Rather, communities should not build on floodplains as those areas are subject to constant environmental changes. Although dam removal will undercut the ability to regulate water movement and distribution, the riparian zones will return to more natural states and stimulate the growth of native species.	Thank you for your comment and statement regarding communities not being built in the floodplain. However as described in Section 1.9 Introduction to Columbia River System Operations, the 14 Federal projects that are referred to as the Columbia River System include both storage projects and run of river projects. The lower Snake River projects are all run of river projects with limited storage capacity, and therefore limited ability to 'control' flows to prevent flooding. As reported in Section 3.9, Section 7.7.11, and Table 7-1, there is no elevated flood risk for any of the EIS alternatives.
6561	1	dskreid@gmail.com	N/A	I'd rather see deep, cool pool water being released to drop the temperature of the water downstream of the dams in order to maintain appropriate temperatures for returning fish.	The co-lead agencies agree with your concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used the current high quality information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. The study results indicate that the operations of the CRS do impact water temperature but the CRS has limited ability to reduce temperatures in the lower Snake and Columbia rivers outside of Dworshak dam operations. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool. Drier and warmer years such as 2015, as summarized in NOAAs 2015 Adult Sockeye Salmon Passage Report (September 2016, National Marine Fisheries Service document) point out that tributary temperatures in the Okanogan and Salmon rivers were above 25C. To take advantage of Dworshak Dam cool water releases in the summer, cooling water pumps have been installed at Lower Granite and Little Goose adult passage ladders to reduce temperature differentials between ladder and river and to reduce thermal stress during upstream passage. Additional considerations at other locations are included in the Draft EIS.
6565	1	wjclodf@fastmail.fm	N/A	I have been meaning to get this comment in to the CRS EIS. I think it is worthwhile to consider since society is having such a hangup on green house gases. I just scanned the EIS summary and didn't come up with any benefits as a result of irrigated crops in Washington, Oregon, and Idaho. I'm a chemical engineer which training involves all aspects of systems designs identifying inputs and outputs, energy or chemicals, solids or gases as are occurring. Growing crops emit oxygen. A lot of it. The gross affect of NW irrigated agriculture is millions/billions of tons of free oxygen when the plant takes in carbon and affixes it in the agricultural product and releases the oxygen. My quick scan didn't note any discussion of the crops taking the carbon dioxide living it up so to speak and releasing the oxygen. It wouldn't be hard to calculate with the basis being tons of agricultural product per acre. i.e. 7-8	As described in Section 3.12.3 in the Draft EIS, under all Multiple Objective alternatives (MOs) except MO3, crop production is expected to be similar to the No Action Alternative. Therefore, impacts to crop-related carbon sequestration and oxygen production are not expected under these alternatives. Removing 48,000 acres of crops under MO3 could slightly reduce the amount of CO2 uptake, although this effect is minor relative to other effects of MO3 on CO2 emissions, in particular from power generation as described in Section 3.8.3.5 in the Draft EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				tons per acres of alfalfa, bushels of grain, tons of fruit, etc. It is a big plus for irrigated crops which I don't think they have been credited. Taking the dams out of the lower Snake would severely hamper irrigation capability, no reservoirs.	
6572	1	osagehick@outlook.com	N/A	The lower Snake River dams have the ability to quickly increase power production when demand is higher. Northwest demand for electricity is higher in the winter when winds are at their lowest levels and the sun sets much earlier in the day. Wind and solar facilities do not have this quick response capability. Without hydro power to fill in the numerous gaps every year, the power grid will falter with the fluctuations caused by wind and solar power inconsistencies. The economy and population of the Northwest is growing and hydro power is THE most dependable asset for this growth. We cannot afford sporadic fluctuations in electric power.	The measure to breach the four lower Snake River dams that was evaluated in MO3 was not included in the Preferred Alternative (PA) identified in the Draft EIS. The effects of the PA on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the PA. However, because of the shape of the remaining hydropower generation in the PA, the loss of load probability was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary. The statements in the comment regarding the ability of hydropower to follow load and increase production when needed is consistent with the findings of the EIS. The variability of wind and solar described in the comment is also consistent with discussions in the EIS. See Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907 in the Draft EIS.
6572	2	osagehick@outlook.com	N/A	During all of the 12 years I worked in Walla Walla I collaborated with other biologists on fine-tuning spill levels at the Snake River dams for juvenile and adult salmon passage. I am deeply troubled by the consideration of increased spill at the dams. I am strongly against higher spill without coordinated biological studies and supporting data. The studies and data must involve total participation and pier review from all Tribal, state , local and federal biologists in order to fully justify any increase!! As an example, during an adult Chinook return study I administered at Little Goose dam in the early 2000's, an increase in spill from about 30,000 kcfs to 34,000 kcfs (give or take 1000 kcfs, I don't have a copy of the study to refer to) resulted in over 4000 adults holding up in the forebay because a strong upstream eddy made it impossible for the fish to find the entrance of the ladder. During the study daily adult passage went from less than 10 fish per day to between 300 - 4000 Chinook!	In its analysis of effects, the Draft EIS used current high quality information, including models and studies published in peer review science journals. The co-lead agencies agree with you on developing coordinated studies to assess the effectiveness of the flexible spill operation measure. The Preferred Alternative includes working with regional sovereigns to develop a study that will assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts on juvenile migrants. Where there are known delay issues (e.g. at Little Goose Dam), measures are built into the flexible spill operation to address these issues.
6572	3	osagehick@outlook.com	N/A	Increased spill without biological data to support it could also cause increases up to 50% in power rates. A rise in the cost of electricity could affect industry, small businesses, employment, the homeless crisis and even lower income people who are already struggling to take care of their family.	The EIS recognizes the concern voiced in the comment regarding increasing power rates. It is unclear which alternative the comment refers to, however under the Preferred Alternative, which includes juvenile fish passage spill operations contemplated under the 2019-2021 Spill Operation Agreement, the rate pressure is 2.7 percent relative to the No Action Alternative. This rate pressure is not comparable to the up to 50 percent increases under MO3 (which includes breaching of the four lower Snake River dams) or MO4 (spill up to 125 percent TDG during spring and summer) mentioned in the comment. The comment that increases in utility costs can adversely affect vulnerable groups is consistent with discussions in the EIS. The Environmental Justice analysis in Section 3.18.3 and Chapter 7, provides further detail on the potential disproportionate effects to Tribal, low-income and minority populations. Regarding the biological data to support spill, the Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored, as will the effects to generating resources around the basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
6572	4	osagehick@outlook.com	N/A	A final argument against higher spill is that the Snake River dams will do more to meet lower carbon emissions in the Northwest than solar or wind power could ever hope to accomplish. Lower Snake River dams directly and indirectly create thousands of jobs in the region. A short list includes employment in agricultural irrigation and crop shipping, farm jobs in planting, harvest and fertilizing. Recreation related employment that the dams provide includes sporting equipment, pleasure boating, guides and outfitters, camping and day uses. Hotel and restaurant jobs round out the economic benefits.	The comment about increased greenhouse gas emissions is consistent with the findings of the MO3 greenhouse gas emissions analysis (see Section 3.8.3.5) as well as the carbon compliance sensitivity presented in Table 3-166 in Section 3.7.3.5. The EIS describes the regional economic effects of navigation (Section 3.10), power supply (Section 3.7), irrigation (Section 3.12), and recreation (Section 3.11) under the No Action Alternative.
6576	1	lakescommission@gmail.com	Lakes Commission	In reviewing the Preferred Alternative (PA) with our narrow regional focus and in talking with your technical team, it appears there will be negligible changes or impacts to Lake Pend Oreille under this proposal. Our concerns have been related to MO4, which proposed to lower Lake Pend Oreille up to three feet during the summer months, eliminating the stable summer pool that is required under the Congressional authorization for Albeni Falls Dam. Without the opportunity to query your team following the official release of the draft PA, due to the pandemic, we are not completely confident we understand the complexity of the PA (i.e. flex spill), but it does seem clear that the potential operational change that we were concerned about under MO4 has been removed.	The McNary Flow Augmentation measure in MO4 that drafted Lake Pend Oreille in the summer was not selected for the Preferred Alternative. Lake Pend Oreille's elevation and Albeni Falls Dam's outflow are the same in the Preferred Alternative as they were in the No Action Alternative. Flexible spill does not apply to Albeni Falls Dam.
6584	1	Danny DeFranco	Washington Cattlemen's Association	1. Introduction This EIS was drafted in response to the need to review and update operations, maintenance, and configuration of the 14 multiple purpose dams and facilities, which significantly impact our membership. The topography of the Snake River region differs greatly from some of the areas of the Columbia River System (CRS). The geographic scope and climate vary greatly throughout this entire system and it should be noted that there cannot be a one-size fits all analysis.	Analysis in Chapters 3, 4, 6, and 7 analyzed effects of the alternatives at each project by different geographic region (A through D). For example, Region A includes three projects geographically located in the upper basin - Hungry Horse and Libby in Montana and Albeni Falls in Idaho. Effects of operation, maintenance and configuration to each one of those projects are analyzed separately. Similarly, the analysis for the remaining 11 projects is broken out by region and focuses on each respective geographic scope.
6584	2	Danny DeFranco	Washington Cattlemen's Association	2.4 Areas of Controversy Dam Breaching Breaching of the four lower Snake River Dams has been a controversy for decades. The EIS correctly identifies that for any breach to occur, new congressional authority would be needed along with funding. It also correctly notes that dam breaching is a complex and polarized issue that does not have a simple solution. The WCA and our members have previously submitted comments and participated in public listening sessions opposing breaching of the four lower Snake River Dams.	Thank you for your comment.
6584	3	Danny DeFranco	Washington Cattlemen's Association	Fish Modeling The EIS correctly used two different approaches to estimate how changes to the CRS operations would change the rates of adult salmon and steelhead returns to the Columbia and Snake Rivers. It is commendable that both of these approaches were used as it shows transparency as well as a wellrounded analysis.	The NMFS COMPASS/Life Cycle models and the CSS models use different statistical approaches and input variables. Both are able to provide a good fit to recent survival, and travel time estimates, but the models do have substantially contrasting forecasts for these metrics under hypothetical scenarios of CRS operations with respect to flow and spill. The Fish Technical Teams for the EIS made the decision to present results from both sets of models for the final evaluation, along with descriptions of methods. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. Please see Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
6584	4	Danny DeFranco	Washington Cattlemen's Association	Reintroduction The concept of reintroduction, is again, one that is complex in nature as well as one that requires indepth analysis and sound, peer reviewed science to help make determinations. The EIS correctly identifies that a coordinated approach is needed and that there are gaps in information. Steps to develop a framework and fill the informational gaps are taking place.	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020, the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
6584	5	Danny DeFranco	Washington Cattlemen's Association	Water Quality This is a very concerning section as it states that there are elevated water temperatures in the Columbia River Basin due to regular climatic events and climate variability, along with regional controversy regarding the role that the federal agencies may play in higher water temperatures. This management section must undergo serious scrutiny. Any conclusion regarding causation for water temperatures must be based upon peer reviewed, sound science, not blanket statements of fault.	Consistent with the requirements of NEPA, the co-lead agencies are using up-to-date, high quality, and relevant information and models in the alternative analysis. Both CE-QUAL W2 and HEC-RAS have been calibrated and peer-reviewed by respected scientists from Portland State University, EPA and the USGS, as well as many cooperating agencies. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). Additionally, the EIS has undergone a third party, neutral Independent Expert Peer Review on the tools used, as well as the assumptions and conclusions in the EIS.
6584	6	Danny DeFranco	Washington Cattlemen's Association	5. Multiple Objectives 1 through 4 The WCA concurs with the EIS that the multiple objectives 1 through 4 are not ideal to meeting EIS objectives as set forth. The No Action Alternative would be the best alternative for the agriculture industry, which would still somewhat meet the objectives as set forth.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. The Preferred Alternative was designed to meet the multiple statutes, authorizations, and objectives described in the EIS, and was determined to result in more beneficial effects across these objectives than the No Action Alternative. See 7.3.1 for additional information.
6584	7	Danny DeFranco	Washington Cattlemen's Association	10. Preferred Alternative The WCA supports the EIS and co-lead agencies work on identifying a way to best meet purposes and objectives which are distinct and of great importance to all parties. The preferred alternative is a collaboration from each of the models along with the no action alternative, that allowed for refinement and targeting of the benefits of each alternative. WCA fully supports that no dams are being breached in this preferred alternative and that impacts are being mitigated while adding flexibility to meet water needs inclusive of flood risk, irrigation, and hydropower, all of which are concerns to our membership. This preferred alternative also has ongoing test and evaluations regarding effectiveness of these operations as they relate to fish mortality. Decisions should be made on sound, peer-reviewed science, and continuing to monitor these species as they are of concern, is of utmost importance.	Thank you for the comment.
6588	1	rkrehbiel@defenders.org	Defenders of Wildlife	We strongly recommend that you conduct a more thorough and complete analysis and provide additional opportunities for public comments and engagement, particularly considering that the current public health crisis has led to the cancelation of in-person public hearings	To ensure adequate opportunity for the public to provide comments on the Draft EIS, the agencies hosted an online comment platform, providing mailing addresses for written comments, and hosted a series of public comment meetings by telephone.The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website reminded the public on April 9, that they should plan to submit comments by the close of the comment period.
6588	2	rkrehbiel@defenders.org	Defenders of Wildlife	I. The DEIS Does Not Deliver the Holistic Solution Needed to Recover Wildlife and Support Rural Economies. Our organizations share the belief that the lower Snake River can be restored in a way that benefits everyone. To ensure the sustainable recovery of salmon and other endangered wildlife, the four lower Snake River dams must be breached. The services the dams provide, though, can and should be replaced. Through strategic planning and investments, state and federal governments can build the infrastructure needed to replace the services provided by these dams, including energy production7, transportation of agricultural goods, and irrigation.8 Making these investments now will decrease local communities reliance on these dams, allowing our region to more quickly and easily transition to operating without them. Breaching the lower Snake River dams is critical to recovering wild salmon and steelhead in the Snake River basin. Rebuilding Snake River salmon runs will greatly benefit endangered Southern Resident orcas, support coastal and inland fishing businesses, and sustain the many tribes who, under various treaties, have reserved their right to harvest healthy and abundant salmon runs as they have since time immemorial. The Action Agencies evaluated breaching these four dams under Multiple Objective	The co-lead agencies have used high-quality information and the best available science in the analysis of the alternatives included in the EIS. The EIS set forth eight objectives which, in tandem with the Purpose and Need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. As described in Chapter 7 of the FEIS, the preferred alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective Alternative 3 (MO3), which includes breaching the four lower Snake River dams. The preferred alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply and greenhouse gas emissions, while minimizing adverse impacts to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Section 3.5 provides a summary of the fish analysis for the No Action Alternative and four of the multiple objective alternatives. Chapter 7 provides a summary of the fish analysis for the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Alternative 3 in the DEIS. However, while the Action Agencies looked at some of the transition investments needed to accompany dam breaching, their assessment was narrowly focused, overestimated transition costs, and ignored key findings in energy sector expert reports.9 The Action Agencies Preferred Alternative does not provide the holistic plan that the region needs. Essentially, the Preferred Alternative is a continuation of the flexible spill agreement already agreed to for 2020 and 2021 by the states of Washington and Oregon, the Nez Perce Tribe, and BPA. At best, the business-as-usual approach of the Preferred Alternative will result in half as many salmon returning to the mouth of the Columbia as there would be under a dam breaching scenario, and this issue will likely compound each year.10 While increasing spill is an important short-term action for salmon, the only viable long-term solution is breaching the dams and restoring the lower Snake River. The Action Agencies have chosen a timid step when our region needs a bold, long-term, sustainable plan in which federal, state, and tribal agencies work together to solve these interlocking and complex issues. 7 Energy Strategies. 2018. Lower Snake River Dams Power Replacement Study: Assessing the technical feasibility and costs of clean energy replacement portfolios. March 2018. Independent study commissioned by the Northwest Energy Coalition. Available at: https://nwenergy.org/featured/lsrdstudy/ 8 EcoNorthwest. 2019. Lower Snake River Dams Economic Tradeoffs of Removal. July 29, 2019. Independent study commissioned by Vulcan Inc. Available at: https://econw.com/projects-collection/2019/7/29/lowersnake-river-dams-economic-tradeoffs-of-removal 9 DEIS at 3-913, lines 27519 27550 and at 3-1481, tables 3-308, 3-309 10 Estimated salmon returns under each scenario were based on CSS smolt-to-adult-ratios and quantified by Dr. Michelle Dehart of the Fish Passage Center during a webinar to the Southern Resident Orca Recovery Task Force on September 27th, 2018. Webinar is available at: https://pspwa.app.box.com/s/l0je55acwx7hjcxqfrc9uys72c4eg1dz/file/322691991990 4 Many such solutions can be found through emerging conversations among stakeholders in the Pacific Northwest, including Governor Inslees Lower Snake River Stakeholder Process. Through these collaborative dialogues, stakeholders identified the types of investments needed to support local communities after the dams are breached.11 Restoring salmon runs by breaching the four lower Snake River dams is necessary to put Southern Resident orcas on the path towards survival, but to do this, we all need to work together. The Pacific Northwest does not have to choose between orcas and clean energy or between fishing and farming communities. The DEIS ignores these important realities and reinforces existing divisions within our region.	targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets. Regarding Southern Resident Killer Whales (SRKW), the population dynamics of the SRKW are complicated, and there is no one factor that contributes to the overall success of this species; however, the co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW. The co-lead agencies are committed to ongoing coordination with stakeholders through a variety of forums. In areas where we have appropriate authority, we will continue to be strong regional partners.
6588	3	rkrehbiel@defenders.org	Defenders of Wildlife	II. The DEIS Fails to Satisfy National Environmental Policy Act requirements. A. The National Environmental Policy Act. The National Environmental Policy Act (NEPA) requires that to the fullest extent possible all federal agencies must complete a comprehensive environmental impact statement in connection with actions that significantly affect the environment.12 In enacting NEPA, Congress recognized the profound impact of human activities, including resource exploitation, on the environment and declared a national policy to create and maintain conditions under which man and nature can exist in productive harmony.13 NEPA has two fundamental two goals: (1) to ensure that the agency will have detailed information on significant environmental impacts when it makes decisions; and (2) to guarantee that this information will be available to a larger audience.14 (i) NEPA requires the Action Agencies to take a hard look at environmental consequences of their actions. To advance its clear policy objectives, NEPA establishes action-forcing procedures that require agencies to take a hard look at environmental consequences.15 A hard look requires a meaningful comparison of the environmental consequences of all alternatives, including the proposed alternative.16 A hard look does not allow the agency to take a soft touch or brush-off of negative effects.17, 18 To have taken the required hard look, the Action Agencies must utilize 11 Lower Snake River Dams Stakeholder Engagement Report. March 6th, 2020. Prepared by Kramer Consulting, Ross Strategic, and White Bluffs Consulting. Available at: https://www.governor.wa.gov/sites/default/files/Final%20Draft%20LSRD%20Report.pdf 12 42 U.S.C 4332. 13 42 U.S.C. 4331(a). 14 Envtl. Prot. Info. Ctr. v. Blackwell, 389 F. Supp. 2d 1174, 1184 (N.D. Cal. 2004) (quoting Neighbors of Cuddy Mt. v. Alexander, 303 F.3d 1059, 1063 (9th Cir. 2002)); see also Earth Island v. U.S. Forest Serv., 351 F.3d 1291, 1300 (9th Cir. 2003) (NEPA requires that a federal agency consider every significant aspect of the environmental impact of a proposed action . . . [and] inform the public that it has indeed considered environmental concerns in its decision-making process.). 15 Metcalf v. Daley, 214 F.3d 1135, 1141 (9th Cir. 2000) (quoting Robertson v. Methow Valley Citizens Council, 490 U.S. 332, 348 (1989)). 16 Ctr. for Biological Diversity v. U.S. Dept of Interior, 623 F.3d 633, 646 (9th Cir. 2010). 17 Native Ecosystems Council v. U.S. Forest Serv., 428 F.3d 1233, 1241 (9th Cir. 2005). 18 Native Ecosystems Council v. U.S. Forest Serv., 428 F.3d 1233, 1241 (9th Cir. 2005). 5 public comment and the best available scientific information.19 By focusing agency attention in this way, NEPA ensures that the agency will not act on incomplete information, only to regret its decision after it is too late to correct.20 (ii) NEPA requires the Action Agencies to assess all reasonable alternatives. The heart of NEPA analysis requires the Action Agencies to [r]igorously explore and objectively evaluate all reasonable alternatives to the proposed action and provide reasons for declining to comprehensively analyze any alternative which was eliminated from the analysis.21 While NEPA imposes no requirement to choose the least environmentally detrimental alternative for action, it does mandate that for each alternative, the agency must consider relative scientific findings on the likely environmental impacts.22 (iii) NEPA requires the Action Agencies to consider direct, indirect, and cumulative impacts of their actions. In analyzing the Preferred Alternative, no action alternative, and all other reasonable alternatives, the Action Agencies failed to properly consider the three types of impacts: direct, indirect, and cumulative.23 Direct effects are caused by the action and occur at the same time and place, while indirect effects are caused by the action and are later in time or farther removed in distance, but are still reasonably foreseeable ... [and] may include growth inducing effects.24 Cumulative impacts include impacts on the environment resulting from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions, by any person or agency, and impacts resulting from individually minor but collectively significant actions taking place over a period of time.25 (iv) The Action Agencies must respond to contrary opposing views and expert comments. The Action Agencies must satisfy NEPAs requirements to explain opposing viewpoints and their rationale for choosing one viewpoint over the other.26 When an informed objection to an agencys alternative(s) is presented, the Action Agencies have a duty to give a viable proposed alternative due consideration.27 A NEPA analysis is inadequate if it fails to disclose responsible scientific opposition to agency actions.28 Courts have set aside NEPA analyses where the Action Agencies failed to respond to scientific analysis that calls into question the agencys assumptions or conclusions.29 As an example, the Action Agencies must respond to opposing scientific viewpoints 19 Biodiversity Cons. Alliance v. Jiron, 762 F.3d 1036, 1086 (10th Cir. 2014) (internal citation omitted). 20 Marsh v. Or. Natural Res. Council, 490 U.S. 360, 371 (1989) (citation omitted). 21 42 U.S.C 4332(C)(iii); 40 C.F.R. 1502.14(a). 22 See, e.g., Robertson v. Methow Valley Citizens Council, 490 U.S. 332, 350-51 (1989). 23 40 C.F.R. 1508.25(c); Colo. Envtl. Coal., 185 F.3d at 1176. 24 40 C.F.R. 1508.8; see also Utahns for Better Transp., 305 F.3d at 1174. 25 40 C.F.R. 1508.7. 26 40 C.F.R. 1502.9(b). 27 See NRDC v. Evans, 168 F. Supp.2d 1149 (N.D. Cal. 2001). 28 Navajo Nation v. U.S. Forest Serv., 479 F.3d 1024, 1056 (9th Cir. 2007). 29 Cal. v. Block, 690 F.2d at 770-71 (stating that NEPAs requirement that responsible opposing viewpoints are included in the final impact statement reflects the paramount Congressional desire to internalize opposing viewpoints into the decision-making process to ensure that an agency is cognizant of all the 6 objectively and in good faith, including those of the governments own experts like the Fish Passage Center.30	The CRSO EIS includes an analysis of direct, indirect and cumulative effects consistent with 40 C.F.R. 1508.25(c). The direct and indirect effects analysis is included in Chapters 3 and 7 and the cumulative effects analysis is included in Chapters 6 and 7. The cumulative effects analysis in Chapter 6 sets the stage for the analysis in Chapter 7 by discussing how past and present actions are considered in the analysis, and then identifies over 20 reasonably foreseeable future actions that may cumulatively affect resources affected by CRS operations, maintenance and configuration. This analysis includes the cumulative effects to fish, including salmon and steelhead from varied actions, including population growth, water withdrawals, additional renewable energy development and fishery management plans, among others. The co-lead agencies have clarified the language in Chapters 6 and 7 to acknowledge the cumulative effects analysis does include consideration of the climate change analysis in Chapters 4 and 7 as well as the mitigation information provided in Chapters 5 and 7. The co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as cooperating agencies, and over 30 of those invited agreed to participate. Staff from the Cooperating Agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation, maintenance and configuration of the dams in the CRS. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The draft EIS was subjected to two internal agency reviews by Corps of Engineers reviewers not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective Alternative 3 (MO3), which includes breaching the four lower Snake River dams. The Preferred Alternative also meets most other EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Section 3.5 provides a summary of the fish analysis for the No Action Alternative and four of the multiple objective alternatives. Chapter 7 provides a summary of the fish analysis for the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets. Finally, the co-lead agencies evaluated many different flow and spill levels and as well as seasonal patterns for when flows are enhanced or reduced. The Preferred Alternative represents an operation that provides a balanced approach between spring and summer flow and spill levels to benefit salmon and steelhead, while also providing benefits to resident fish in the upper portion of the Columbia Basin.
6588	4	rkrehbiel@defenders.org	Defenders of Wildlife	B. The Action Agencies Failed to Take a Hard Look at the Direct Impacts on Columbia Basin Salmonids and Failed to Adequately Assess the Alternative of Breaching the Four Lower Snake River Dams. The CRSO has substantially affected the natural ecological structure and functionality of the Columbia River watershed.31 The Columbia River system is one of the largest in North America, with a drainage area of over a quarter million square miles.32 What was once an ecologically functional river system providing ecological goods and services for fish, wildlife, and humans has been transformed into a carefully regulated environment.33 Dam operations and alterations have resulted in the loss of once important spawning grounds and rearing habitat, and has significantly degraded migration corridors for salmon and steelhead populations.34 Many of our organizations provided the Action Agencies with citations to relevant peer-reviewed studies regarding Columbia and Snake River salmon restoration, and we provide those here again. (Appendix A). After decades of protection and management, most federally protected salmonid populations in the Columbia and Snake rivers remain in poor condition and at high risk of extinction.35 Despite great efforts to restore these stocks, several evolutionary significant units (ESUs) still remain at high risk of extinction.36 Approximately 65% of the extant interior Columbia Basin ESUs are considered at high risk of extinction, ~29% are at a maintained risk of extinction (the second-highest risk category), only 4% are considered viable, and just 2.5% are considered highly viable.37 Although returns of some Chinook salmon populations have recently increased depending on good ocean conditions, these are mostly dominated by hatchery fish instead of wild fish.38 Extensive scientific papers and federal reports demonstrate that the CRSO has caused substantial harm and decreased the likelihood of survival and recovery of these threatened and endangered salmon and steelhead populations throughout the Columbia Basin.39 The National Marine Fisheries environmental trade-offs that are implicit in a decision) (citing Andrus v. Sierra Club, 442 U.S. 347, 350 (1979); Appalachian Mountain Club v. Brinegar, 394 F. Supp. 105, 121 (D.N.H. 1975)). 30 W. Watersheds Project, 632 F.3d at 492-93 (agency violated NEPA by giving short shrift to a deluge of concerns from its own experts and other federal and state agencies). 31 Sheer and Steel 2006, Caudill et al. 2007, White 2011, Moore et al. 2012, Naiman et al. 2012, Rechisky et al. 2013, Harnish et al. 2014, Rollet et al. 2014. 32 Kammerer 1990. 33 Trefethen 2013; White 2011. 34 BiOp 2014. 35 BiOp 2014, NWFSC 2015; West Coast Salmon and Steelhead Listings http://www.westcoast.fisheries.noaa.gov/protected_species/salmon_steelhead/salmon_and_steelhead_listin	The purpose of the CRSO EIS was to provide a strategy for operations and configurations of the 14 dams in the CRS over the next 25 years. Operation of the CRS requires balancing competing interests and managing trade-offs to allow the co-lead agencies to meet their multiple congressionally authorized purposes. The EIS team, with cooperating agency staff as team members, developed a range of alternatives that would allow the co-lead agencies to analyze future actions, identify effects to multiple resources, and identify future operations that would allow the balancing of multiple priorities. As stated in the EIS, the baseline for this analysis and comparison is 2016, the date the Notice of Intent was issued to develop the EIS. At no time was the EIS expected nor intended by the co-lead agencies to be an examination or comparison of the existing system against historic conditions, nor would it be appropriate to do so. The co-lead agencies did, however, analyze the direct, indirect and cumulative effects to resources affected by the CRS, and these results are included in Chapters 3, 4, 6, and 7. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws, such as the Endangered Species Act (ESA), to evaluate impacts to listed species such as sockeye and steelhead. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally-authorized purposes while minimizing impacts to affected ESA species and their habitats. Both human-caused and natural factors that are outside the responsibility and control of the co-lead federal agencies, also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the Columbia River System requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models

				gs/salmon_and_steelhead_listings.html. 36 2016 Status Reviews of Listed Salmon & Steelhead http://www.westcoast.fisheries.noaa.gov/publications/status_reviews/salmon_steelhead/2016_status_revie w.html. 37 BiOp 2014 38 BiOp 2014. 39 Raymond 1979, Kareiva et al. 2000, Dauble et al. 2003, Reischel and Bjornn 2003, Boggs et al. 2004, Williams et al. 2005, Caudill et al. 2007, Waples et al. 2008, Keefer et al. 2008, Caudill et al. 2013, Rechisky et al. 2013, BiOp 2014, Harnish et al. 2014, Keefer and Caudill 2015, ISAB 2016, Perry et al. 2016, Bond et al. 2017. 7 Service (NMFS) recognizes that dam presence and operations in the Basin directly and indirectly contribute to most of the mortality of juvenile and adult salmonids migrating through the system.40 Within the Columbia Basin, the annual abundance, population growth rate, and returns-perspawner (e.g., smolt-to-adult returns) for most wild salmonid populations (i.e., not hatchery origin) are less than 1.0.41 This indicates that wild salmonid population abundance is declining, populations are not growing, and returns are decreasing generation after generation, even though hatcheryorigin salmon production may be increasing. In fact, in the Columbia Basin, most salmonid population abundance is below the minimum viable abundance numbers estimated by the Interior Columbia Technical Recover Team.42 The longer a population remains at low abundance, the greater the likelihood of extinction from stochastic events, inbreeding, and environmental disturbance.43 At moderate and high risk of extinction, salmon and steelhead populations throughout the interior Columbia Basin can remain at relatively low numbers for decades without reaching recovery goals.44 Dam structures and operations substantially delay the recovery of salmonid species because they lead to several factors that reduce the likelihood of survival. Impacts from dam operations in the Snake and Columbia rivers that directly limit the survival and recovery of salmon and steelhead populations include, but are not limited to: juvenile mortality at mainstem hydro projects, physical passage barriers, reduced water flows that delay passage and lead to mortality, altered channel morphology, fallbacks, straying of adults and juveniles, drastic temperature fluctuations in both reservoirs and fish ladders.45 Indirect adverse impacts from dam operations include, but are not limited to: increase of infectious diseases due to lacerations during dam passage, increased predation by birds within reservoirs, increased predation by birds and marine mammals in estuarine areas, changes in water flows and temperature, decreased oxygen levels within reservoirs, delayed or latent mortality, and amplified climate change effects.46 For example, changes in stream flow and velocity associated with reservoirs affect salmon migration patterns in the Columbia Basin.47 Dam operations affect downstream habitat quality by increasing water temperatures, increasing metabolic demand of fishes, and inducing straying.48 Disease outbreaks are also associated with higher water temperatures.49 The Action Agencies have failed to adequately evaluate all reasonable alternatives to both reduce and offset these impacts associated with continued CRSO operations to avoid jeopardy on ESA 40 BiOp 2014. 41 BiOp 2014, NWFSC 2015. 42 BiOp 2014, NWFSC 2015. 43 Purvis et al. 2000, Hutchings and Reynolds 2004 44 McElhany et al. 2000. 45 Kareiva et al. 2000, Dauble et al. 2003, Reischel and Bjornn 2003, Boggs et al. 2004, Bottom et al. 2005, Williams et al. 2005, Caudill et al. 2007, Keefer et al. 2008, Caudill et al. 2013, Rechisky et al. 2013, BiOp 2014, Harnish et al. 2014, Keefer and Caudill 2015, ISAB 2016, Perry et al. 2016, Bond et al. 2017. 46 Elliott et al. 1997, Beeman and Maule 2006, Good et al. 2007, Bryant 2009, Mantua et al. 2010, Abdul-Aziz et al. 2011, Dietrich et al. 2011, Evans et al. 2012, Keefer et al. 2012, Caudill et al. 2013, Dittmer 2013, Sebring et al. 2013, Crozier 2015, Erhardt 2015, Justice et al. 2017. 47 Tiffan et al. 2009. 48 Olden and Naiman 2010. 49 Miller et al. 2014. 8 protected salmonids and maintain or restore essential habitat features that prevent adverse modification of critical habitat. The Action Agencies have failed in the DEIS to take the necessary hard look to evaluate all reasonable alternatives to both reduce and offset the impacts associated with continued dam operations to avoid jeopardy on ESA-protected species and maintain or restore essential habitat features that prevent adverse modification of critical habitat. More effective actions such as dam removal or modification of dam operations are necessary to eliminate the adverse modification of critical habitat for salmonids and to change the status quo. Indeed, scientific evidence shows that dam removal would provide the much-needed boost to salmon and eel populations, help the long-term restoration of riverine ecosystems, increase marine nutrients input from the ocean to freshwater habitat, and improve physical conditions within tributaries and mainstem habitat.50 The Action Agencies failed to fully assess the environmental benefits of dam removal in the EIS. Dam removal is becoming increasingly common as a management strategy for environmental restoration.51 In the Pacific Northwest, over a dozen dams have been already removed.52 Currently, four large dams on the Klamath River in California are scheduled for removal in 2022, showing that large dam removal projects are feasible.53 The EIS should analyze the potential ecosystem services of dam breaching, not only on salmonid recovery but also critical habitat of protected species. Restoring natural river flows and hydrodynamics, by removing dams and passage barriers, would likely benefit the ecological functioning of the entire river basin by increasing salmon survival, potentially increasing spawning areas, increasing salmon run numbers, and ultimately increasing nutrient supply to the interior basin.54 For example, Chinook salmon in the Rogue River spawned in newly deposited gravel just a few months after dam removal. A major benefit to removing impediments to water flow would be increased survival of smolts as well as increased passage for adult salmonids to historical spawning grounds.55 Dam removal would also increase flow volumes which decreases travel time of smolts and thus increases salmonid juvenile survivorship.56 In addition, flow restoration stabilizes water temperatures preventing drastic changes in water temperatures (increasing or declining) that are known to affect fish survival.57 Dam removal would also prevent fish concentration in certain areas that are easily predated by birds and marine mammals.58 Finally, dam removal may restore ecological important nutrient flows and sediment dynamics that are essential for ecosystem health and productivity.59 50 Bednarek 2001, Pejchar and Warner 2001, Hart and Poff 2002, Stanley and Doyle 2003, Duda et al. 2008, Brenkman et al. 2008, Hitt et al. 2012, Null et al. 2014, Pess et al. 2014, Hatten et al. 2015, Tonra et al. 2015, Quiones et al. 2015, Hamilton et al. 2016, Magilligan et al. 2016b, 2016a, Cubley and Brown 2016. 51 Loomis 1996, Pohl 2002, Winter and Crain 2008, OConnor et al. 2015, Borisova et al. 2017. 52 Ryan Bellmore et al. 2016. 53 Jacobs, J.P. In addition, removal costs could be lower than the funds needed to maintain old infrastructure and the mitigation and restoration projects associated with the impacts of dam systems.62 The DEIS vastly underestimates both the CRSO impacts on salmonids and the value that removing the four lower Snake River dams would have on the species. What is clear is that the Preferred Alternative will not bring the Columbia Rivers treasured salmonids any closer to recovery. We expect the Action Agencies to fully and accurately assess the impacts of their status quo approach to managing the Columbia River System on salmon, including the scientific information cited to in this letter and included in Appendix A, and revisit the alternative of removing the four lower Snake River dams as the best first step towards sustainable salmon recovery.	predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a substantial contribution towards recovery. The co-lead agencies conclude the expected outcomes for salmon and steelhead associated with MO3 are appropriately acknowledged and framed appropriately with impacts to other authorized purposes.
6588	5	rkrehbiel@defenders.org	Defenders of Wildlife	C. The Action Agencies Failed to Fully Consider Indirect Impacts to Southern Resident Orcas, Failed to Include the Best Available Scientific Information, and Failed to Address Contrary Viewpoints. The nations leading Southern Resident orca scientists and experts have unequivocally stated that if we do not breach the four lower Snake River dams, it may be impossible to prevent the extinction of the Southern Resident orcas.63 Extensive comment letters to the Action Agencies during the February 2017 NEPA scoping period focused on the connection between Columbia Basin salmon and Southern Resident orcas.64 Many of our organizations provided the Action Agencies with a detailed bibliography of peer-reviewed studies that highlight the importance of restoring Snake River salmon to recover Southern Resident orcas, and we provide one here again in Appendix B. Despite the extensive scientific information provided to the Action Agencies, the DEIS has only two paragraphs dedicated to Southern Resident orcas.65 Without any citations, the DEIS boldly claims that, [t]he food available to Southern Resident killer whales from the lower Snake River population is only a small percentage of their overall diet. Changes to food availability may change the whales foraging behavior patterns slightly but will not change their overall condition or population dynamics.66 Under this assumption, the DEIS falsely concludes that any increase in salmon (under any alternative) would provide only a negligible or minor benefit to the Southern Residents.67 This statement is flatly inaccurate for several reasons. 60 Bednarek 2001, Hart and Poff 2002, Stanley and Doyle 2003, Hogg et al. 2013, Auerbach et al. 2014, Null et al. 2014, Gillette et al. 2016, Magilligan et al. 2016b, 2016a, Bohrerova et al. 2017. 61 Winter and Crain 2008, Marks et al. 2010, Tonra et al. 2015, Magilligan et al. 2016b, Cubley and Brown 2016, Bohrerova et al. 2017. 62 Loomis 1996, Gosnell and Kelly 2010. 63 Giles, D.A., S.K. Wasser, D. Bain, K. Ayres, V. Veirs, and S. Veirs. 2018. Letter to Governor Jay Inslee and Southern Resident Orca Recovery Task Force Members. October 15, 2018. Available at: https://www.documentcloud.org/documents/5002547-Orca-Scientists-Letter-10-15-18-Final.html. 64 DEIS at 1-14, line 377. 65 DEIS at 3-685, lines 20,959 20,982. 66 DEIS at 3-759, table 3-106. 67 Id. 10 First, Snake River salmon, both currently and historically, are important food sources for Southern Resident orcas. Like many predators, Southern Resident orcas travel long distances in search of their prey. Data from satellite-tagged orcas show that all three pods spend time foraging for salmon off the west coast in the spring and winter.68 During this time, the Southern Residents spend a considerable amount of time at the mouth of the Columbia River foraging for salmon as they return to spawn in the Columbia Basin, including the Snake River and its tributaries.69 Using this information, NMFS and the Washington Department of Fish and Wildlife assessed the relative importance of various salmon runs to the Southern Residents. That analysis identified Snake River	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.

				Chinook salmon runs as two of the top ten most important salmon stocks to the orcas in their current diet.70 Historically, the importance of these stocks was likely much higher given that there were significantly more Snake River salmon prior to dam construction.71 Before the lower Snake River dams were built, half of all salmon returning to the Columbia Basin were bound for spawning grounds in the Snake River and its tributaries.72 At that time, the Washington Department of Fisheries warned in its 1949 annual report that the dams could have lasting impacts on salmon and the local economy: Another serious threat to the Columbia river fishery is the proposed construction by the U.S. Army Engineers of Ice Harbor and three other dams on the lower Snake river between Pasco, Wash. and Lewiston, Idaho to provide slackwater navigation and a relatively minor block of power. The development would remove part of the cost of waterborne shipping from the shipper and place it on the taxpayer, jeopardizing more than one-half of the Columbia River salmon production in exchange for 148 miles of subsidized barge route. The transportation saving to the shipper would amount to $2,000,000 annually, while salmon runs having a wholesale value of about $9,000,000 would be threatened with destruction.73	
6588	6	rkrehbiel@defenders.org	Defenders of Wildlife	Second, wild Snake River Chinook salmon are particularly important to orcas due to their size and fat content. While salmon spend their adult years in the Pacific Ocean, they build up enough fat and 68 J. Acoust. Soc. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
6588	7	rkrehbiel@defenders.org	Defenders of Wildlife	Third, Southern Resident orca recovery will require state, federal, and tribal governments to protect and rebuild salmon runs throughout the Southern Resident orcas range, which includes the mouth of the Columbia River where orcas forage during late winter and early spring.78 The DEIS myopically argues that salmon recovery efforts should be focused in the Salish Sea.79 The consequences of neglecting other foraging areas would divert resources to just half of the orcas annual range. The Southern Residents typically spend summer and fall in the Salish Sea (which includes Puget Sound) foraging for salmon returning to local rivers from June through November. In the winter, the orcas typically head out into the Pacific Ocean, foraging for salmon as far south as Monterey Bay, California.80 During this time, images from aerial photogrammetry typically document a decline in the orcas body condition.81 Reproductive-age females showed some of the greatest signs of nutritional stress during this time, and as a result, over two-thirds of Southern Resident orca pregnancies are terminated prematurely (including many dangerous late-term miscarriages) because of nutritional stress.82 If salmon recovery efforts were solely focused in the Salish Sea, as the Action Agencies suggest, orcas would not have sufficient food during the time of year they need it most.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
6588	8	rkrehbiel@defenders.org	Defenders of Wildlife	Fourth, restoring the lower Snake River will provide more salmon to Southern Resident orcas than almost any other salmon recovery project being considered. In the 2008 Recovery Plan for the Southern Resident Orcas, NMFS stated that [p]erhaps the single greatest change in food availability for resident killer whales since the late 1800s has been the decline of salmon in the Columbia River basin. In that same plan, NMFS went on to state that the Columbia-Snake River Basin, by orders of magnitude, has the largest potential for increasing Chinook salmon abundance throughout the 74 Groot, C. and L. Margolis (ed.). 1991. Pacific salmon life histories. University of British Columbia Press. Vancouver British Columbia. 75 Id. 76 NMFS, West Coast Region. November 2017. ESA Recovery Plan for Snake River Spring/Summer Chinook Salmon (Oncorhynchus tshawytscha) and Snake River Basin Steelhead (Oncorhynchus mykiss). Available at: https://www.fisheries.noaa.gov/resource/document/recovery-plan-snake-river-spring-summer-chinooksalmon-and-snake-river-basin. 77 Wasser, S.K. et al., Population growth is limited by nutritional impacts on pregnancy success in endangered Southern Resident killer whales (Orcinus orca), PLoS ONE 12:e0179824 (2017). 78 Zamon, J. E., T. J. Guy, K. Balcomb, D. Ellifrit. 2007. Winter observations of southern resident killer whales (Orcinus orca) near the Columbia River plume during the 2005 spring Chinook salmon (Oncorhynchus tshawytscha) spawning migration. Northwestern Naturalist, 88:193-198. 79 DEIS at 3-685, lines 20,969 20,975. 80 Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales: Draft Biological Report. National Marine Fisheries Service, September 2019. Available: https://www.fisheries.noaa.gov/action/critical-habitat-southern-resident-killer-whale. 81 Fearnbach, H. et al, Using aerial photogrammetry to detect changes in body condition of endangered southern resident killer whales, Endang Species Res 35:175-180. Available at: https://doi.org/10.3354/esr00883. 82 Wasser, S.K. et al., Population growth is limited by nutritional impacts on pregnancy success in endangered Southern Resident killer whales (Orcinus orca), PLoS ONE 12: e0179824 (2017). 12 Southern Residents range.83 Additionally, because Snake River salmon spawn in high alpine, federally protected Wilderness areas, these runs are more insulated from the impacts of climate change and development, providing orcas with both a large and more reliable source of food into the future.84 According to the Fish Passage Center, breaching all four lower Snake River dams and increasing spill on the lower Columbia dams would result in roughly 1 million adult Chinook salmon returning to the mouth of the Columbia River annually.85 By removing these dams, we can also increase salmon access to roughly 5,500 miles of free-flowing spawning habitat in Central Idaho and northeast Oregon, much of which is both climate-resilient and federally protected.86 For all of these reasons, the future of Snake River salmon is of the utmost importance to the future of the Southern Resident orcas. Many of these points and studies have already been provided to the Action Agencies, and yet the DEIS did not mention any of them. We expect the Action Agencies to fully and accurately consider the impacts of the status quo approach to managing the Columbia River System on Southern Resident orcas, including the scientific information cited in this comment letter, those listed below in Appendix B, and in the two documents submitted with this letter as attachments: Attachment A Salmon and Orca Scientist White Paper and Attachment B Chapter 2 of the Fish Passage Centers 2019 Comparative Survival Study (CSS) Report.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
6588	9	rkrehbiel@defenders.org	Defenders of Wildlife	D. The Action Agencies Failed to Fully Assess the Cumulative Impacts of Climate Change on Salmon and Failed to Include the Best Scientific Information on Climate Change Impacts. In the DEIS, the Action Agencies failed to fully assess the impacts of climate change on reservoir temperatures and what that would mean for salmon survival. Anthropogenic climate change is one of the greatest threats to wildlife both globally and locally. On the lower Snake River, water temperatures in the large, slackwater reservoirs created by the four dams increase every year, posing increasing risks to salmon.87 These lethal temperatures kill both adult and juvenile salmon and at the same time benefit invasive, salmon-eating fish found throughout these reservoirs.88 83 NMFS (2008) Recovery Plan for Southern Resident Killer Whales (Orcinus orca), p. II-82. Available at: http://www.nwr.noaa.gov/Marine-Mammals/Whales-Dolphins-Porpoise/Killer-Whales/ESA-Status/OrcaRecovery-Plan.cfm. 84 Bain, D., D.A. Giles, M.J. Filardo, H. Schaller, and R. Williams. 2020. Southern Resident killer whales and Columbia/Snake River Chinook: A review of the available scientific evidence. February 2020. 85 Estimated salmon returns under each scenario were based on CSS smolt-to-adult-ratios and quantified by Dr. Michelle Dehart of the Fish Passage Center during a webinar to the Southern Resident Orca Recovery Task Force on September 27th, 2018. Webinar is available at: https://pspwa.app.box.com/s/l0je55acwx7hjcxqfrc9uys72c4eg1dz/file/322691991990 86 Bain, D., D.A. Giles, M.J. Filardo, H. Schaller, and R.	The co-lead agencies analyzed the effects of the operation, maintenance, and configuration of the CRS projects on resources affected by the CRS, including the potential to improve conditions for ESA-listed species. The co-lead agencies also looked at the cumulative effects of other actions in Chapters 6 and 7 of the EIS. Regarding climate change analysis, the climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change and, unfortunately, they have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. Therefore it was not possible to reliably model water temperature changes under climate change for incorporation to either of the fish models. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature and anadromous fish. These analyses are documented in Section 4.2.3 for the MO Alternatives and Section 7.8.4 for the Preferred Alternative. Historically, water temperatures in the lower Snake River were warm (USGS 1960, 1961, 1964; Corps 2002a). Observed historic water temperatures in show that average monthly water temperatures during July and August, in the 1950s, averaged 7 to 8 degrees Fahrenheit higher than today's conditions, while maximum daily differences were 10 to 12 degrees Fahrenheit higher. The differences observed in the lower Snake River today, as compared to historical conditions, are a result of the middle and upper Snake River reservoirs combined with the influence that Dworshak Dam operations. The effects of these operations are discussed under the No Action Alternative. The co-lead agencies analysis shows that under a dam breaching scenario, nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more

				Williams. 2020. Southern Resident killer whales and Columbia/Snake River Chinook: A review of the available scientific evidence. February 2020. 87 Save Our Wild Salmon Coalition, 2019. Hot Water Report 2019. Issue 9, August 30th, 2019. Available at: https://www.wildsalmon.org/news-and-media/sos-blog/hot-water-report-2019-august-23rd-2.html. 88 NMFS, West Coast Region. November 2017. ESA Recovery Plan for Snake River Spring/Summer Chinook Salmon (Oncorhynchus tshawytscha) and Snake River Basin Steelhead (Oncorhynchus mykiss). Available at: https://www.fisheries.noaa.gov/resource/document/recovery-plan-snake-river-spring-summer-chinooksalmon-and-snake-river-basin. 13 First, the DEIS does not provide any information about the efficacy of current efforts to mitigate the effects of lethal water temperatures on salmon. While the DEIS mentions the currently utilized option of releasing cool water from the Dworshak Dam into the Snake River, it does not discuss how effective that strategy has been or how effective it is likely to be given ever increasing temperatures.89 Over the last several years, Columbia and Snake River temperatures have exceeded 20 degrees Celsius (68 degrees Fahrenheit).90 At this temperature, salmon have difficulty migrating upstream, and mortality from stress and disease increases.91 The Fish Passage Center has stated that, under a climate change scenario, the long-recognized and largely unaddressed problem of high water temperatures in the [Columbia and Snake Rivers] becomes an ever-increasing threat to the survival of salmon.92 It is critical for the Action Agencies to assess the efficacy of current water temperature cooling measures, particularly into the future, in order to evaluate mitigation strategies under all alternatives in the DEIS.	susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. The models showed minor changes in the Columbia River under this alternative, indicating that the operations of the CRS dams have a limited ability to reduce temperatures in the lower Columbia River. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. The co-lead agencies contracted with the Fish Passage Center (FPC) to produce the CSS modeling results presented in the Draft EIS. Any additional modeling that was not presented in the Draft EIS is not part of the CRSO EIS and was not developed by the co-lead and cooperating agencies.
6588	10	rkrehbiel@defenders.org	Defenders of Wildlife	Second, the DEIS does not rely on appropriate models to predict climate change impacts on water temperatures and salmon. The model used as part of the water quality assessment provided in Appendix D of the DEIS looked at water temperatures over a 5-year period from 2011 to 2015. This model does not predict how climate change will further impact temperatures in either an impounded or free-flowing river.93 The DEIS also used a model developed by the River Management Joint Operating Committee (RMJOC), but, as the DEIS notes, the full RMJOC assessment of climate change is not complete: A second part of the RMJOC-II study, which is not yet available, will provide an assessment of how these projected unregulated streamflows perform in a regulated Columbia River system.94 The DEIS also states that this climate model does not include predicted water temperatures.95 These two models fail to accurately assess of how climate change will increase water temperatures in reservoirs and, thus, how that will impact salmon survival.	The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. Therefore, it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3).
6588	11	rkrehbiel@defenders.org	Defenders of Wildlife	This is particularly timely given that water temperature in these reservoirs are the subject of yet another lawsuit against the federal government for mismanagement of the river and its wildlife. In December 2019, the Ninth Circuit Court of Appeals ruled that under the Clean Water Act, 33 U.S.C. 1313(d)(2), the Environmental Protection Agency has an immediate duty to set a Total Maximum Daily Limits (TMDLs) for water temperature in the Columbia and Snake Rivers because the states of Washington and Oregon have conclusively refused to do so.96 Recently, the court denied the agencys request for an en banc and panel rehearing of this issue, so the ruling stands.97	Thank you for your comment. For information regarding the recently issued TMDL for temperature in the Columbia and lower Snake rivers, please see https://www.epa.gov/columbiariver/tmdl-temperature-columbia-and-lower-snake-rivers.
6588	12	rkrehbiel@defenders.org	Defenders of Wildlife	Independent research and computer modeling suggest that even with elevated air temperatures, a free-flowing Snake River will be more resilient to climate change and water temperatures will be significantly lower than they would be in a dammed river.98 Additional modeling by the 89 DEIS at 2-16. 90 Fish Passage Center, Requested data summaries and actions regarding sockeye adult fish passage and water temperature issues in the Columbia and Snake rivers (Oct. 28, 2015). 91 National Marine Fisheries Service, 2015 Adult Sockeye Salmon Passage Report, pp. 2022 (2016). 92 Fish Passage Center, Review of April 2016 Draft of NMFS report 2015 Sockeye Salmon Passage Report, p. 1 (May 4, 2016). 93 DEIS at D-2-1, line 1085. 94 DEIS at 4-2, lines 60-62. 95 DEIS at 4-2, line 69. 96 Columbia Riverkeeper v. Wheeler, 944 F.3d 1204, 1211 (9th Cir. 2019). 97 Riverkeeper v. Wheeler, No. 18-35982, 2020 U.S. App. LEXIS 9897, at *1 (9th Cir. Mar. 30, 2020). 98 Shultz, M. and M. Johnson. 2017. Columbia Riverkeeper White Paper: Computer modeling shows that Lower Snake River dams caused dangerously hot water for salmon in 2015. Available at: 14 Environmental Protection Agency demonstrates that the presence of multiple dams on the Columbia and Snake Rivers has warmed the rivers to unsafe levels for salmon.99 Despite this, the DEIS claims that climate change impacts will be the same on the lower Snake River regardless of if dams are breached or not.100 This may be because the models cited in the DEIS did not examine water temperatures when considering the long-term climate change impacts. We strongly urge the Action Agencies to rectify this glaring error and update its analyses by including these other models.	The analysis of MO3, which includes breaching the four lower Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. However, at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. The water temperature model used to analyze all EIS alternatives underwent review by experts outside of the co-lead agencies, including scientists from the USEPA, USGS, and Portland State University. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/HEC-RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the draft TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC-RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059). The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at the resolution required (river vs. regional or global scale) at this time. Therefore, it was not possible to reliably model water temperature changes under climate change for incorporation into either of the fish models. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature and anadromous fish in Section 4.2.3.
6588	13	rkrehbiel@defenders.org	Defenders of Wildlife	The Action Agencies must also assess the impacts that increasing reservoir water temperatures will have on predation of juvenile salmon by invasive, non-native fish. Several studies have indicated that predation from these invasive species is a major and potentially limiting factor for salmon recovery in the Columbia Basin.101 The DEIS notes that dams have altered habitat in a way that generally favors non-native and invasive species at the expense of native species.102 Further, the DEIS states that most of the invasive species are warm water fish while native species are cold water adapted.103 It goes on to state that warmer water temperatures increase the predation rate of invasive fish on salmonids.104 However, this analysis stops too short.	The qualitative analyses mentioned in this comment concluded that scenarios with increasing temperatures would likely increase predation on juvenile salmon. Water temperature under each alternative was modeled and provided to the quantitative fish models which include a component to consider the relationship between water temperature and predation risk into the results for runs where numerical models were available. Further analyses included qualitative consideration of increased predation risk in scenarios where water temperature would be expected to change. In the case of climate change, there is not sufficient information to numerically model temperature changes because the resolution of climate models is at a regional or global scale instead of specific to water bodies, so these effects were also described qualitatively.
6588	14	rkrehbiel@defenders.org	Defenders of Wildlife	Later in the DEIS, the Action Agencies claim that a free-flowing Snake River may increase the presence of many invasive salmon predators, contradicting their earlier point. 105 As stated above, dam breaching is expected to significantly reduce overall in-stream water temperatures, which will make the habitat less suitable to invasive, warm-water adapted species. Many of these invasive species are also adapted to slackwater environments like lakes and ponds, which are typically warmer than free-flowing rivers. In the 2017 Recovery Plan for Snake River Spring/Summer Chinook Salmon and Steelhead, NMFS stated, when discussing dam breaching, that, It is likely that the return to a more riverine system in this portion of the Snake River could reduce salmon predation losses to native and non-native invasive fishes that have taken advantage of the reservoir habitat, such as northern pikeminnow and walleye. Migrating smolts would be less exposed due to decreased travel times through the lower Snake River.106 The EIS must integrate these findings. https://www.columbiariverkeeper.org/sites/default/files/2017/08/Computer-modeling-shows-that-LowerSnake-River-dams-caused-dangerously-hot-water-for-salmon-in-2015-final.pdf. 99 EPA Region 10. RBM-10 Columbia River Temperature TMDL-Preliminary Technical Information. Presentation to Columbia River Tribes. August 14, 2018. November 2017. ESA Recovery Plan for Snake River Spring/Summer Chinook Salmon (Oncorhynchus tshawytscha) and Snake River Basin Steelhead (Oncorhynchus mykiss). Available at: https://www.fisheries.noaa.gov/resource/document/recovery-plan-snake-river-spring-summer-chinooksalmon-and-snake-river-basin. 15 Breaching the four lower Snake River dams would not only decrease salmon migration time, it would also decrease lethal water temperatures and invasive predators. The Action Agencies should recognize these added benefits to salmon survival when assessing the alternative of dam breaching in the EIS.	The fish analyses for MO3, which includes the dam breach measure, indicated that a free-flowing river would, indeed result in fewer non-native, predatory fish. The CRSO EIS also recognizes, however, that a more natural riverine environment could result in more habitat available for avian predators to nest and could increase predation on salmon in the Snake River corridor by these birds. While some cooler water temperatures may be observed in the summer under MO3, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. Overall, the conclusion in the Draft EIS is that MO3 would be beneficial to anadromous fish for a number of reasons, but other considerations must also be considered in the selection of a Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets certain objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6588	15	rkrehbiel@defenders.org	Defenders of Wildlife	E. The DEIS Mischaracterizes the Impacts of Dam Breaching on Other Wildlife. The Action Agencies did not sufficiently analyze all alternatives because they did not present a complete or accurate characterization of the various actions and potential direct, indirect, or cumulative impacts they may have, such as impacts on other wildlife. As written, the DEIS conveys much more optimism for maintaining the status quo than any of the alternatives, particularly dam breaching. The Action Agencies must provide additional information, context, and analysis to help guide decision making. While the DEIS lists actions the Action Agencies have taken to support ESA-listed fish, it does not provide any information about the effectiveness of these projects or programs.107 While the amount of money committed to fund these projects is impressive, it is unclear how successful these actions have been, particularly given that none of the ESA-listed salmon in the Columbia Basin have been recovered.108 Given the limited time and resources available, it is important for the Action Agencies to assess their current efforts to demonstrate that these investments are making timely and meaningful strides towards recovery. In particular, the Action Agencies should provide information about the degree to which habitat restoration and predator removal efforts have contributed to salmon recovery and returns. Additionally, the Action Agencies must report their success in a way that puts it in the context of Basin-wide salmon recovery. One of the most important data points for salmon recovery is the smolt-to-adult ratio (SAR): the number of adults that return to spawn for every smolt that hatches.109 SARs are used by managers to assess the progress of salmon runs towards recovery goals.110 Current SARs for spring/summer Chinook salmon are estimated to be around 1%.111 The Northwest Power and Conservation Council has stated that 2% SARs are needed to maintain current populations, while 4-6% is needed for recovery.112 Rather than relying on this metric, the Action Agencies instead use misleading data points without putting them in the appropriate context. For example, when discussing juvenile passage over the dams, the DEIS reports juvenile survival rates and migration times.113 While these numbers are indeed important to consider, viewing them in isolation paints a more optimistic narrative for salmon than the reality. These numbers only provide the percentage of fish that survive going from the forebay of a dam to its tailrace. While these survival rates seem high, these percentages do not account for deaths that occur between dams in reservoirs either from latent mortality or from predation. Models from the 107 DEIS at 2-30, table 2-3. 108 See: NMFS, West Coast Salmon & Steelhead Listings.	Regarding wildlife impacts, this information is provided in Section 3.6. Impacts specific to implementation of MO3 are provided in Section 3.6.3.5. It should be noted that the 2-6% Smolt-to-Adult return (SAR) target referenced in this comment refers to the Northwest Power and Conservation Councils (Council's) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the analysis of the Preferred Alternative, the co-lead agencies believe their actions will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. The per-dam survival metric is both accurate and useful in measuring changes in near field survival at the dams due to structural modifications (e.g., surface passage routes) or operation changes (changes to spill levels or spill patterns). The per-dam survival estimates are multiplicative in nature and the improvements in at-dam survival over the past 10 years has been shown to contribute to improvements in total in-river survival of smolts migrating through the CRS especially for steelhead. These figures were used to provide context in the affected environment Section. The co-lead agencies do not agree with this comment that states that this information was misleading in nature or presented in isolation. The focus of this EIS analysis presented throughout this review draft in Section 3.5 and Chapter 7 utilized multiple metrics, including total in-river survival, travel time, powerhouse passage rates, and Smolt-to-Adult return rates. Additional charts detailing recent in-river survival estimates will be added to the FEIS. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Regarding hatchery impacts associated with MO3, as described in Section 3.5, the co-lead agencies anticipate that changes in hatchery funding may occur as needs and obligations shift. The co-lead agencies do not claim that hatchery operations would be shuttered. As noted in Section 3.5, the co-lead agencies also recognize that there would be transitional needs that would be addressed in the additional mitigation measures for MO3 discussed in Chapter 5. Additionally, the Bonneville F&W Program funding for offsite mitigation projects in the Snake River Basin, implemented by local, state, Tribal, and Federal entities, would be reviewed, and potentially adjusted. Any changes of this nature would be implemented over time as the

Survival data smolt to adult queries. http://www.fpc.org/survival/smolttoadult_queries.html. 110 Id. 111 CSS 2016 Annual Report, Chapter 7. Available at: http://www.fpc.org/documents/CSS/2016%20CSS%20Annual%20Report.pdf. 112 Id. 113 DEIS at 3-302, figure 3-112. 16 Fish Passage Center suggest that only 54% of juvenile salmon spawning from above Lower Granite Dam survive the journey over Bonneville Dam.114 The Action Agencies frequently state that hatchery operations, which currently produce 85% of Chinook salmon smolts in the region, would be shuttered if the lower Snake River dams were breached.115 Should this happen, the Action Agencies claim that any potential gains from river restoration would be lost or greatly reduced.116 However, while the Action Agencies would no longer be required to mitigate the impact of these dams, hatchery production would not necessarily need to halt immediately.117	effectiveness of dam breaching is observed and would be done in consultation with fish and wildlife managers, regulatory agencies, and the Council. Consistent with this, offsite mitigation projects for the other CRS dams would be reviewed and could be adjusted as operations change over time. Proposed project modifications would be coordinated with project sponsors and regional stakeholders to determine appropriate funding levels.
6588	16	rkrehbiel@defenders.org	Defenders of Wildlife	The Action Agencies are presenting the public with a false choice. The Action Agencies analysis of the environmental impacts of dam breaching largely assumes that the only necessary management activity to occur would be the removal of the four earthen berms, and that the environment would be left to respond on its own. For example, the DEIS focuses on increased sedimentation and invasive plant colonization that would follow dam breaching.118 Dam breaching, though, presents an opportunity for active riparian and in-river habitat restoration, such as dredging contaminated soils behind the dams, planting trees and native shrubs in newly exposed areas, removing invasive species, and excavating areas for wetlands. The Action Agencies propose actions like these to mitigate potential impacts at the confluence of the Columbia and Snake Rivers, yet they fail to propose similar steps for newly exposed habitat along the Snake River due to dam breaching.119	MO3 in Section 3.6 describes the short-term and long-term effects of dam breaching on the terrestrial and wetland environment. The specific details of the mitigation plan for MO3 have not been developed, but are generally included in Chapter 5. If MO3 was selected and authorized by Congress, an implementation plan and associated National Environmental Policy Act (NEPA) analysis would be prepared that would include site specific information that details the construction, breaching, disposal, and mitigation actions required to implement MO3, as well as identifying all of the associated permitting for this action. As discussed in Chapter 5, mitigation proposed includes "Develop and implement a planting plan to restore arid, native plant communities on approximately 13,000 acres of lands along the lower Snake River."
6588	17	rkrehbiel@defenders.org	Defenders of Wildlife	The DEIS also emphasizes the negative impacts of dam breaching on local wildlife populations in the short term, only briefly mentioning the long-term benefits to species.120 Dam breaching will significantly alter the landscape by restoring the Snake River to its original state. Through active restoration, riparian forests and wetlands can recover relatively quickly. Riparian corridors are also one of the most important habitat types for many wildlife species, and while many species will be disturbed in the short-term by dam breaching activities, it is most likely that native wildlife throughout the region will greatly benefit from a restored, free-flowing Snake River. For instance, following dam removal on the Elwha River in Olympic National Parks, biologists found 1,741 spawning adult Chinook on the river, 75% of which were spawning above the recently removed lower dam.121 Following extensive dam removal on the Rouge River (which began in 2008), fall Chinook populations doubled every year from 2015 2018, despite severe droughts, El Nino, and other environmental factors that usually decrease salmon returns.122 We encourage the Action Agencies to provide a more robust and appropriately balanced assessment of the long-term benefits a free-flowing river would provide to local wildlife. 114 CSS 2019 Annual Report, Appendix, Table 1, available at: http://www.fpc.org/documents/CSS/2019CSSAnnualReport.pdf 115 DEIS at 3-548, lines 16,542 16,543 116 DEIS at 3-550, lines 16,628-16,629 and at 3-558, lines 16,876 16,881 117 For example, funding to support removal of dams on the Elwha River was coupled with the construction and management of a new hatchery to aid in the recovery of salmon on that river. 118 DEIS at 3-749, lines 23,044 23,054. 119 DEIS at 3-756, line 23,324. 120 DEIS from 3-746 through 3-755. 121 Seattle Times. 2013. Salmon Are Booming in Oregons Rogue River. Dam Removal May Be Why. June 26,2018 Water Deeply. Available at: https://www.newsdeeply.com/water/articles/2018/06/26/salmon-are-booming-inoregons-rogue-river-dam-removal-may-be-why 17	Long-term effects to wildlife are included for MO3, the alternative that includes the measure to breach the lower Snake River dams, in Section 3.6.3. This section contains a description of short-term and long-term effects and describes impacts to wildlife from dam breaching. As stated in Section 3.6.3, site-specific NEPA would be necessary to analyze dam breaching, if it were selected. This site specific NEPA would also include more extensive analysis of impacts of dam breaching on vegetation and wildlife resources.
6588	18	rkrehbiel@defenders.org	Defenders of Wildlife	III. The Action Agencies Must Also Consult with NMFS to Ensure that Their Actions Do Not Jeopardize Listed Species or Adversely Modify Critical Habitat. Under the Endangered Species Act, 16 U.S.C. 1531 et seq.(ESA), federal agencies may not take an action if it is likely to result in harm to listed species or affect critical habitat. The ESA aims to conserve species of fish, wildlife, and plants facing extinction as well as the ecosystems upon which endangered and threatened species depend.123 The ESA defines critical habitat as the physical and biological features that are essential to the conservation of listed species.124 For example, in the Columbia Basin, migratory corridors are considered critical habitat defined by several primary constituent elements such as water temperature, water quantity, water quality, and safe passage.125 The ESA also requires each agency to use the best scientific and commercial data available.126 The Action Agencies must consult with NMFS on any actions that may directly or indirectly affect ESA-listed species and their critical habitat, which includes actions related to the CRSO.127 Specifically, section 7 requires that the Action Agencies insure that any action authorized, funded, or carried out by such agency . . . is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of designed critical habitat.128 To jeopardize the continued existence of a species means to engage in an action that reasonably would be expected, directly or indirectly, to reduce appreciably the likelihood of both the survival and recovery of a listed species in the wild by reducing the reproduction, numbers, or distribution of that species.129 NEPAs implementing regulations require that, to the fullest extent possible, agencies must prepare draft environmental impact statements concurrently with and integrated with environmental impact analyses and related surveys and studies that the ESA requires.130 Along with the other alternatives analyzed in the DEIS, the Preferred Alternative certainly may affect several ESA-listed species, including salmon and orcas, as well as the critical habitat for these species, triggering the ESAs requirements. The Action Agencies operation and maintenance of the CRSO directly impacts about 13 runs of salmon ESUs and steelhead distinct population segments (DPSs) listed under the ESA within the Columbia-Snake watershed. ESA-protected salmon and steelhead species that the Preferred Alternative will affect include: 1) Snake River fall Chinook salmon; 2) Snake River spring/summer Chinook salmon; 3) Snake River steelhead (Oncorhynchus mykiss); 4) Upper Columbia River spring Chinook salmon; 5) Upper Columbia River steelhead; 6) Middle Columbia River steelhead; 7) Snake River sockeye salmon (Oncorhynchus nerka); 8) Columbia River chum salmon (Oncorhynchus keta); 9) Lower Columbia River Chinook salmon; 10) Lower Columbia River coho salmon (Oncorhynchus kisutch); 11) Lower Columbia River steelhead; 123 16 U.S.C. 1531(a)(4); 16 U.S.C. 1531(b). 124 16 U.S.C 1532(5)(A). 125 Critical Habitat for 15 Distinct Population Segments (DPSs) of salmon and steelhead (Oncorhynchus spp.) in Washington, Oregon and Idaho, 50 C.F.R. 226.212. 126 16 U.S.C. 1536(a)(2). 127 16 U.S.C. 1536(a)(2). 128 Id. 129 50 C.F.R. 402.02. 130 40 C.F.R. 1502.25. 18 12) Upper Willamette River Chinook salmon; and 13) Upper Willamette River steelhead.131 NMFS has designated critical habitat for 12 of these 13 salmonid species.132 In addition, the CRSO indirectly impacts the endangered Southern Resident orca DPS that depend on the Basins salmon populations as a vital prey source.133 Along with the other alternatives analyzed in the DEIS, the Preferred Alternative may affect several ESA-listed species both directly and indirectly, including salmon, steelhead, and Southern Resident orcas, triggering the requirements of the ESA. Because the CRSO may affect ESA-listed species and their critical habitat, the Action Agencies must consult with NMFS on the Preferred Alternative. After consultation, investigation, and analysis, NMFS must prepare a new biological opinion to evaluate the effects of the proposed actions on the survival and recovery of listed species and designated critical habitat. Under the ESA, recovery means improvement in the status of listed species to the point at which listing is no longer appropriate.134 NMFSs biological opinion should include a summary of the science-based information upon which the opinion is based, an analysis of the effects of the agency actions on listed species and critical habitat, and whether the actions are likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of critical habitat135 If NMFS determines that the Preferred Alternative may jeopardize the survival of ESA-listed species or adversely modify a species critical habitat, the action must be modified or eliminated. Therefore, NMFSs biological opinion must specify all reasonable and prudent alternatives that avoid jeopardy and make recommendations that promote the conservation of the listed species or species critical habitat.136	The co-lead agencies are actively engaged with NMFS and USFWS in the ESA Section 7 process. The Biological Assessment that the co-lead agencies submitted to NMFS and USFWS was included as Appendix V to the Draft EIS. Final biological opinions on the effects of our proposed actions to ESA-listed species under their jurisdiction, will be appended to the FEIS. The co-lead agencies will implement the Terms and Conditions identified in the respective BiOps to minimize adverse effects to ESA-listed species.
6588	19	rkrehbiel@defenders.org	Defenders of Wildlife	IV. Other Comments Generally, the DEIS is poorly written and organized. Finding information is difficult, and it is not communicated clearly. It also contains several contradictions and grammatical errors. We expect the Action Agencies to thoroughly edit this document and organize it in a more sensible and accessible way before publishing the Final EIS.	The co-lead agencies analyzed the integrated operation, maintenance, and configuration of the 14 projects that comprise the CRS. Because the CRS has a broad geographic reach, is subject to numerous legal mandates, and implicates numerous complicated and contested subjects, the analysis is necessarily lengthy. The Final EIS will expand the table of contents that was in the draft EIS to assist readers in finding specific topics. The EIS also includes an index, so the public knows where to look for detailed analysis in either the main body of the EIS or the appendices.
6588	20	rkrehbiel@defenders.org	Defenders of Wildlife	Additionally, the DEIS contains several inaccurate statements regarding grizzly bears (Ursus arctos horribilis).137 We are providing corrections to those statements and the relevant supporting science here: 1. The current Bitterroot population is not an experimental population. A 10J rule was approved for the Bitterroot Ecosystem, but it was never implemented. Only bears that are physically moved by wildlife managers into the ecosystem would be considered part of this 131 Washington Dept of Fish and Wildlife, ESA Listed Washington Salmonids, available at: http://wdfw.wa.gov/conservation/endangered/esa/wa_esa_listed_map.pdf. 132 See: NMFS, West Coast Salmon & Steelhead Listings. http://www.westcoast.fisheries.noaa.gov/protected_species/salmon_steelhead/salmon_and_steelhead_listin gs/salmon_and_steelhead_listings.html. 133 NMFS. Killer whale (Orcinus orca), available at: http://www.nmfs.noaa.gov/pr/species/mammals/whales/killer-whale.html. 134 50 C.F.R. 402.02. 135 50 C.F.R. 402.14(h)(3). 136 16 U.S.C. 1536(b)(3)(A). 137 DEIS at 3-682. 19 experimental population. To date, no bears have been physically moved by wildlife managers into the ecosystem.	Thank you for the correction. The final EIS will reflect the correct listing status for grizzly bear in the Bitterroot recovery area.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				The bears living in the Bitterroot Ecosystem today immigrated there on their own. These bears are fully protected as a threatened species under the ESA.138	
6588	21	rkrehbiel@defenders.org	Defenders of Wildlife	2. The size of the current grizzly bear population in the North Cascades Ecosystem is largely unknown but is typically estimated to be lower than 20 bears.139	The Draft EIS states in Section 3.6.2.6 that the "grizzly bear population in Washington is estimated to be fewer than 20 animals." This agrees with the comment.
6588	22	rkrehbiel@defenders.org	Defenders of Wildlife	3. The DEIS left out the Selkirk population of grizzly bears in northeast Washington, directly west of the Cabinet-Yaak Ecosystem. The Selkirk Ecosystem is estimated to have around 80 grizzly bears. This ecosystem is well within the boundaries of the CRSO analysis.140	The Selkirk Mountains Ecosystem (SE) is located in northern Idaho, northeastern Washington, and southeast British Columbia and has an estimated 80 grizzly bears. It is located between the Kootenai River on the east and the Pend Oreille River to the west. While the boundaries of the SE come very close to the study area that would have been subject to the analysis in Vegetation, Wetlands, Wildlife, and Floodplains, but the two do not overlap. Therefore, it was not described or analyzed in the Draft EIS. However, effects to grizzly bear by CRS regions were described in Section 3.6.3, regardless of whether effects overlapped with an ecosystem recovery zone.
6588	23	rkrehbiel@defenders.org	Defenders of Wildlife	Finally, section 3.16, Cultural Resources, is not written in a culturally sensitive way. For example, a single paragraph describes all Native American cultures and history in the CRSO area from 2000 B.C. to 1720 A.D.141 This vastly oversimplifies the diversity of tribes and First Nations who have lived in the region since time immemorial. When discussing Christian missionaries, the Action Agencies only acknowledge the role missionaries played in spreading diseases that decimated many Native American communities, but the agencies should also recognize that many missionaries instituted racist systems of violence and oppression (like Indian Schools) that stole children from their families and stripped them of their cultures and languages.142 Throughout this section, the Action Agencies emphasize potential risks to cultural resources and minimize the benefits.143 We recommend that the Action Agencies consult with local tribal governments and officials in order to rewrite this section to more accurately describe the history of Native Americans in the region and the impacts dam breaching would have on their cultural resources and reserved treaty rights.	In Section 3.16, the co-lead agencies have adequately identified the historic context for which to conduct the comparative impact analysis from all of the action alternatives on cultural resources. Additional details about historical events in the Northwest would not have assisted in the comparative analysis between the No Action Alternative and the action alternatives. Content was provided to the co-lead agencies by several Tribes and is incorporated in both Section 3.17 and in other specific locations throughout the document. Some of these locations include 3.17.2 (Tribal perspective summaries), 3.17.2.2 (general overview, including documenting impacts to Tribal culture), and Appendix P (Tribal Perspectives). The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS.
6588	24	rkrehbiel@defenders.org	Defenders of Wildlife	V. Public Engagement Was Severely Curtailed and Has Not Been Meaningful. The Action Agencies failed to provide adequate or meaningful opportunities for the public to comment on the DEIS. It is extremely disingenuous that the public was given only 45 days, the regulatory bare minimum, to provide comments on a document that is almost 8,000 pages long and covers an array of complex issues throughout the region. The Action Agencies provided no justification for shortening the timeline, which was originally scheduled for 120 days.144 Members of Congress and many of our organizations have requested that the Action Agencies extend the public comment period back to its original 120-day timeline.145 138 Federal Register 65 FR 69644, page 69644-69649. U.S. Fish and Wildlife Service. November 17th, 2000. Record of Decision Concerning Grizzly Bear Recovery in the Bitterroot Ecosystem. Available at: https://www.federalregister.gov/documents/2000/11/17/00-29531/record-of-decision-concerninggrizzly-bear-recovery-in-the-bitterroot-ecosystem. 139 Interagency Grizzly Bear Committee. http://igbconline.org/. 140 Id. 141 DEIS at 3-1341, lines 5,609 5,626. 142 DEIS at 3-1343, lines 5,700 5,707. 143 DEIS at 3-1355, lines 6,121 6,133. 144 EIS Scheduled Update. US Army Corps of Engineers, Northwestern Division. April 18, 2019. Available at: https://www.nwd.usace.army.mil/Media/News-Stories/Article/1818002/eis-schedule-update/. 145 News release: Washington state, Oregon lawmakers press Trump Administration to extend Columbia River system environmental impact statement comment period as nation works to address coronavirus pandemic. March 31, 2020. Available at: https://www.murray.senate.gov/public/index.cfm/mobile/newsreleases?ID=D3188FED-5034-4177-971AA96F9A966955. 20 Moreover, many individuals across the region have also been responding to the global public health crisis caused by the spread of COVID-19, leaving the public with even less time to fully or fairly review the DEIS. We strongly recommend that the Action Agencies either extend the public comment period to at least 120 days or provide a supplemental public comment period after the COVID-19 crisis has subsided. A supplemental public comment period was recently provided to solicit additional comments on the North Cascades Grizzly Bear Environmental Impact Statement. Recently, the state Department of Ecology cited the COVID-19 pandemic to justify extending the public comment period for the state environmental review of a proposed dam on the Chehalis River from April 27 to May 27.146 Both of these projects have a much narrower scope and impacts a smaller geography than the CRSO DEIS. It is not unreasonable, especially in light of the current public health crisis, that the Action Agencies would provide additional opportunities for public comment and engagement.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.

Batt, J. J. Skalicky, R. Engle, G. J. Barton, R. L. Fosness, and J.	Thank you for providing this list of references. The co-lead agencies have used current high quality information to analyze the effects of operations, maintenance, and configuration of the CRS projects, including for MO3, the alternative that includes the measure to breach the lower Snake River dams. Chapter 11 of the EIS as well as the respective sections of the EIS include the references the co-lead agencies relied on as part of the CRSO EIS analysis. Without specific comments relating these references to the analysis in the EIS, the co-lead agencies would continue to rely on the current high quality information in the CRSO EIS.

6591	1	derekdelongcc@gmail.com	N/A	I found the report provided extensive information on many common topics regarding the CRSO but I was not able to find any information in the executive summary review in regards to the greater unseen environmental impacts of sediment retention of dams. While ALTERNATIVE 3 (MO3) does briefly mention the positive and negative impacts of dam breaching on fish, riparian and wetland habitats in the Snake River and confluence of the Columbia River it does not mentions sediment retention beyond the time it would take for sediments to be transported away from the reservoir. The role of river sediments in the biogeochemical processes of the ocean and associated estuaries is crucial to the primary producers that form the basis of the food chain of which we all depend on.	The Executive Summary provides a high-level overview of the alternatives and effects, but information specifically regarding sediment transport and quality can be found in Section 3.3 (River Mechanics), Section 3.4 (Water Quality), Sections 7.7.2 and 7.7.3, and Appendices C and D. It is known that the dams within the Snake and Columbia River basins disrupt the movement of sediment, blocking most material from moving downstream to the Columbia delta except for small amounts of fine suspended material that are carried to the ocean. This is further described under the Affected Environment Sediment Supply Section 3.3.2.2. It is also recognized that the operation of the dams has altered sedimentation processes in the lower Columbia River and estuary as described under the Affected Environment Aquatic Habitat Section 3.5.2.2. However the effects of dam construction are not directly analyzed in this EIS. Analysis of other downstream conditions, such as sediment delivery to the delta are outside the scope of this study.
6591	2	derekdelongcc@gmail.com	N/A	To that end I believe the agencies involved with the CRSO should revise their documents so that the roles dams play in preventing crucial sediment transport are taken into consideration: 1. A free flowing river provides both nutrients and mineral transport to the oceans which supports the phytoplankton communities of which are the primary producers of the ocean food web. Studies have found that these communities have begun diminishing due to increased ocean acidity and biogeochemical changes of estuaries and as such the Columbia River System Operations should address these phenomena.	It is known that the dams within the Snake and Columbia River basins disrupt the movement of sediment, blocking most material from moving downstream to the Columbia River delta except for small amounts of fine suspended material that are carried to the ocean. This is further described under the Affected Environment Sediment Supply Section 3.3.2.2. It is also recognized that the operation of the dams has altered sedimentation processes in the lower Columbia River and estuary as described under the Affected Environment Aquatic Habitat Section 3.5.2.2. However, the analysis of the effects on ocean conditions is outside the scope of this study.
6591	3	derekdelongcc@gmail.com	N/A	a. Acidity; Ocean acidity has been increasing globally and the decreasing pH levels in the ocean are expected to have profound impacts on the physiology and metabolism of marine organisms through a disruption of intercellular transport mechanisms. The sediments naturally transported in free flowing rivers act as a buffer in estuaries and as such mitigate the increasing acidity. The damming of rivers prevents these sediments from reaching estuaries and are therefore contributing to increasing ocean acidity that could be mitigated by dam removal.	It is known that the dams within the Snake and Columbia River basins disrupt the movement of sediment, blocking most material from moving downstream to the Columbia River delta except for small amounts of fine suspended material that are carried to the ocean. This is further described under the Affected Environment Sediment Supply Section 3.3.2.2. It is also recognized that the operation of the dams has altered sedimentation processes in the lower Columbia River and estuary as described under the Affected Environment Aquatic Habitat Section 3.5.2.2. However, the analysis of the effects on ocean conditions is outside the scope of this study.
6591	4	derekdelongcc@gmail.com	N/A	b. Biogeochemical changes; Dissolved silica drives the growth of diatoms that form a large part of the phytoplankton biomass and are important contributors to primary production of the ocean. The global contribution of BSi carried by rivers was estimated as 1.05 0.20 Tmol Si year 1 . Combined with the global mean riverine DSi concentration of 150 mol liter 1 , 16% of the gross riverine Si load is delivered to the world ocean as BSi. Sediment retention by dams has a clear negative impact on the biogeochemical processes of the ocean by reducing the amount of minerals and nutrients such as silica available to our primary producers.	It is known that the dams within the Snake and Columbia River basins disrupt the movement of sediment, blocking most material from moving downstream to the Columbia River delta except for small amounts of fine suspended material that are carried to the ocean. This is further described under the Affected Environment Sediment Supply Section 3.3.2.2. It is also recognized that the operation of the dams has altered sedimentation processes in the lower Columbia River and estuary as described under the Affected Environment Aquatic Habitat Section 3.5.2.2. However, the analysis of ocean processes is outside the scope of this study.
6591	5	derekdelongcc@gmail.com	N/A	It goes without saying that ecological processes and services are intrinsically intertwined with economic activity. Therefore any negative and unnecessary costs that can be avoided should be pursued and weighed against any supporting benefits provided, such as the power generation of dams versus the possible trophic cascades caused by lost primary producers. The issues I have brought forth should be considered and taken into advisement by the CRSO for review. Peer reviewed scientific literature that supports any arguments for or against dam removal in regards to sediment transportation role on ocean acidity and biogeochemical ocean changes should also be provided in any revisement.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations.
6592	1	N/A	N/A	The preferred alternative offers unsatisfactory energy production levels and unsatisfactory environmental conditions, especially in regard to population levels of endangered fish species in comparison to all other MOs and the No Action consideration. Under the other alternatives section of the EIS, there are no provisions for some other available options that could offset energy production decreases as well as create long-term benefits for the environments and economies surrounding the current dams and hydroelectric locations the EIS is considering, namely geothermal energy production, distributed energy storage grids, and increasing hydroelectric production in lower impact areas not associated with the EIS. The National Renewable Energy Laboratory has a map available (attached) that determines all of the areas considered in the EIS are of moderate to high viability for geothermal power, which, in its largest implementation offers MWh comparable to current energy production provided by the Snake River hydroelectric plants. Breaching the dams and construction of closed-loop geothermal plants that utilize excess water from the increased flow of the rivers as well as non-potable water from wastewater treatment plants and available geothermal fluids would provide minimal environmental impact while providing greater protections for endangered fish species, and the water used in this system is capable of being recycled. Energy surpluses provided by other hydroelectric plants not in the EIS scope could be contained in various distributed energy storage options, mirroring German and Icelandic programs. Various Icelandic sources provide the information that greater than 99% of its energy is based on renewable sources, predominately hydroelectric and geothermal, and they produce a surplus of energy in a land area that is far less than half the size than the regional area described in the EIS; thus the argument of greater viability of geothermal energy in Iceland is minimized by the size of the US regional area outlined in the EIS that is viable for geothermal energy production. This alternative would provide long-term economic incentives in the energy sector and private sectors in both energy production	The comment describes a variety of possible replacement power options with a focus on geothermal energy. The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council (Council) in its 7th Power Plan (7th Power Plan page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission, Section 2.2. Conventional geothermal energy was deemed a secondary resource and enhanced geothermal energy was a tertiary resource in the 7th Power Plan, and thus, were not included in the EIS. The EIS also has examined the use of storage technologies, mentioned in the comment, which were considered a long-term resource of the 7th Power Plan, but have become more commercially available since the release of the 7th Power Plan, and will likely now be considered a primary resource in the Councils 8th Power Plan. See draft EIS, Section 3.7.3.5, Potential Replacement Resources and Associated Costs, for additional details on the replacement resource portfolio identified for Multiple Objective Alternative 3. Hydropower generation at non-Federal dams not included in the Federal Columbia River Power System, which includes the CRS projects, are typically already committed for serving load of other utilities. When these projects produce surplus power, this power is generally traded on the wholesale market, and the EIS analysis incorporated the wholesale market in evaluating the power from the CRS projects. Furthermore, EIS modeling included modeling changes in generation at the major non-Federal hydropower projects that are located downstream of CRS projects to incorporate changes in generation at these projects resulting from changes in outflow of the CRS projects. (See Appendix I.)

				technology and battery technology, which we are currently seeing a rise in due to the increased public awareness of renewable energy options and electric-powered transport systems, as well as the long-term environmental incentives, indigenous cultural preservation/restoration, and other benefits outlined in MO3. This alternative provides an option for increased research and development into technologies, both new and old for energy production and storage, a foothold for companies and stakeholders outside of the region that might be willing to invest in such a program (thus bringing in new investment opportunities), decreases environmental impacts on water/riparian resources, and in the current era of economic uncertainty, provides the possibility of long-term employment opportunities in both the private and public sectors that are potentially greater than those currently offered in the scope of the region outlined in the EIS.	
6594	1	N/A	N/A	Your own study in Chapter 3, pages 548 and 559 discuss that 80-90 % of all juvenile Snake River fish passing CRS projects are hatchery fish. It says the two models projecting fish returns fail to address the loss of hatchery fish and further restoration of habitat (p. 3-548, lines 16557 16558). So positive returns are discussed elsewhere in the report. This is absolutely the wrong approach. The correct approach is to better address what is likely to happen. My request is simple: Put the loss of hatchery fish into both the CSS and COMPASS models so that the real outcomes are conveyed.	Modeling of alternatives for the CRSO EIS did not consider additional mitigation programs such as hatchery production or habitat restoration projects. Mitigation program measures are described in the EIS in Chapter 5. However, it would not be feasible to rerun scenarios of MO3 using NMFS COMPASS and CSS with Snake River hatchery production not included. The COMPASS model relies on the record of hydrosystem survival data estimated with both hatchery and wild-tagged Chinook and steelhead. The NMFS Life Cycle model already reports only wild spawner abundance. Likewise, the CSS Chinook Life Cycle model in the Grande Ronde/Imnaha also only included wild spawners. For both models, density related effects in downstream locations such as the mainstem, estuary, and ocean could only be estimated with hatchery fish present.
6595	1	CommissionersWebPageE-mail@co.yakima.wa.us	Yakima County Commissioners	On behalf the residents of Yakima County, we are writing to express our strenuous opposition to breaching of the Columbia River or Snake River dams. The economic cost to breaching these dams would be disastrous to our residents and local economies. Yakima County agriculture and industry are dependent upon the clean and reliable hydropower provided by these dams. As we prepare for the economic challenges that will result from the COVID-19 emergency, our residents and businesses must be protected from any potential increases in cost for basic utilities. A large jump in the cost of electricity could also have far reaching impact on the price of food: On the production side as irrigation and processing are power-dependent activities. On the supply end for grocers and restaurants who could see an increase in their operational expenses. On a national level as cold storage facilities would experience an unmitigated surge to their fixed costs. These economic impacts would be passed on to consumers and would drive up food prices. While we are supportive of efforts to diversify our electrical sources and protect fish, at this time there is insufficient supply to ensure the dams could be breached without significant and far reaching economic damage.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
6605	1	Charles Tracy	Pacific Fishery Management Council	Council Concerns In accordance with the Councils authorities, the Council has considered the DEIS and the preferred alternative in the context of sustainable fisheries and salmon EFH. The DEIS analysis and preferred alternative are of particular relevance and concern, as the allowable ocean harvest rate of Council-managed fisheries must meet MSA- and ESA- required conservation objectives for multiple stocks, including wild Snake River fall Chinook. Mortalities of ESA-listed populations can impose limitations on Council-area fisheries, even when catch rates of particular ESA-listed fish (fall and spring Chinook salmon) are not substantial. For example, in past years, fisheries have been constrained by the allowable exploitation rate on Snake River wild fall Chinook. The Council is undergoing review of its fisheries with respect to the southern resident killer whale (SRKW) to ensure that conduct of Council salmon fisheries does not adversely affect SRKW via reduction of their primary prey, Chinook salmon. This issue is relevant to the DEIS, as many Columbia River basin Chinook Page 3 salmon stocks are considered among the priority Chinook salmon stocks for increasing abundance to help SRKW recovery.	The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The population dynamics of the SRKW are complicated, and there is no one factor that contributes to overall success of this species; however, the co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be minor. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW. Also, see updated language of effects on SRKWs in Chapter 3.6 and Chapter 7 of the FEIS.
6605	2	Charles Tracy	Pacific Fishery Management Council	Based on the Councils review, we find a number of deficiencies with the DEIS analysis and the selection of the preferred alternative. These are noted here and further discussed below by section. 1. The DEIS does not incorporate the Councils scoping recommendations	The scoping process and comments were used to solicit concerns from the public and establish objectives to focus the evaluation and measures that may address them as part of the CRSO EIS. In addition, all recommendations are evaluated against their ability to meet the Purpose and Need Statement. The co-lead agencies used the scoping process to develop measures to build alternatives to the operations, maintenance and configuration of the CRS. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), The Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Additionally, the co-lead agencies evaluated many different flow and spill levels in the EIS and as well as seasonal patterns for when flows are enhanced or reduced. The Preferred Alternative represents an operation that provides a balanced approach between spring and summer flow and spill levels to benefit salmon and steelhead, while also providing benefits to resident fish in the Columbia Basin.
6605	3	Charles Tracy	Pacific Fishery Management Council	2. The DEIS does not include an anadromous fish-focused alternative in the range of alternatives	The co-lead agencies disagree with the commenter that the Draft EIS does not contain an anadromous fish-focused alternative. All alternatives developed have anadromous fish as two of the objectives. The EIS set forth eight objectives which, in tandem with the purpose and need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call however is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead Agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. For additional information on the alternatives development, see Chapter 2 and Appendix A, which explains why single-objective alternatives were not carried forward for detailed study in the EIS.
6605	4	Charles Tracy	Pacific Fishery Management Council	3. The DEIS analysis does not sufficiently account for the impacts of climate change or avoid and mitigate increased water temperatures	Historically, water temperatures in the lower Snake River were warm (USGS 1960, 1961, 1964; Corps 2002a). Observed historic water temperatures show that average monthly water temperatures during July and August, in the 1950s, averaged 7 to 8 degrees Fahrenheit higher than today's conditions, while maximum daily differences were 10 to 12 degrees Fahrenheit higher. The differences observed in the lower Snake River today, as compared to historical conditions, are a result of the middle and upper Snake River reservoirs combined with the influence that Dworshak Dam operations. The EIS analysis shows that when breaching the four lower Snake River dams, nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. The models showed minor changes in the Columbia River under MO3, indicating that the operations of the CRS dams have a limited ability to reduce temperatures in the lower Columbia River. Summer water temperatures exiting the Snake River are typically 1 to 3 degrees Fahrenheit warmer than the receiving Columbia River temperatures. Even though the cold water released from Dworshak during the summer is less than 50 degree Fahrenheit, the volume of water released is less than one tenth of the flow in the Columbia River. Since the distance between the confluence of the Snake and Columbia Rivers is about 180 miles downstream from Dworshak, the impact on water temperatures is negligible. Regionally high air and water temperatures result in water quality standard exceedances that are beyond the ability of the CRS to cool. Overall the conclusion in the Draft EIS is that MO3 would be beneficial to anadromous fish for a number of reasons, but other objectives must also be considered in the selection of a Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change and, unfortunately, they have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. Therefore it was not possible to reliably model water temperature changes under climate change for incorporation to either of the fish models. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature and anadromous fish. These analyses are documented in Section 4.2.3 for the multiple objective alternatives and Section 7.8.4 for the Preferred Alternative. Overall, the Preferred Alternative is expected to result in benefits to anadromous salmon and steelhead. The analysis in Section 7.8.4 recognizes that some of the benefits to fish from the Preferred Alternative could be offset by the effects of climate change.
6605	5	Charles Tracy	Pacific Fishery Management Council	4. The DEIS does not include an equitable economic analysis of recreational, commercial, and tribal fisheries	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries subsection and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries subsection of Section 3.15.2.1. Fisheries Tribal interests are described in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including Tribal interests (Section 3.11.3.7). Most sections of Chapter 3 include a Tribal Interests Section at the end that attempts to summarize issues by topic.
6605	6	Charles Tracy	Pacific Fishery Management Council	5. The DEIS alternatives analysis is insufficient in assessing the benefits of configurations and operations that restore or improve EFH for salmonids	Section 8.3.5 of the Draft EIS describes EFH and the basic requirements of the Magnuson-Stevens Fishery Conservation and Management Act to consult on a proposed action, and indicates the co-lead agencies are in consultation with the NMFS and USFWS under Section 7 of the ESA. The Assessment of Effects on Essential Fish Habitat Designated Pursuant to the Magnuson-Stevens Fishery Conservation and Management Act for the Preferred Alternative is presented in Chapter 5 of the Biological Assessment of Effects of the Operations and Maintenance of the Federal Columbia River System on ESA-Listed Species.
6605	7	Charles Tracy	Pacific Fishery Management Council	6. The DEIS preferred alternative is not a sufficient improvement over the No Action Alternative and, therefore, fails to meet a number of regional requirements, goals, and objectives for salmon (e.g., Endangered Species Act, Northwest Power Act, Northwest Power and Conservation Council Fish and Wildlife Program Recovery and Harvest Goals, Columbia Basin Partnership Task Force Goals, and state water quality standards).	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple legal responsibilities, including compliance with Section 7 of the Endangered Species Act. Under Section 7(a)(2) of the ESA, the co-lead agencies must insure that any action authorized, funded, or carried out is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species. Section 7(a)(2) does not require the co-lead agencies to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is predicted to benefit salmon and steelhead. It also meets the other objectives for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Chapter 8 of the EIS demonstrates the agencies compliance with applicable laws, including the ESA, MSA and Northwest Power Act. The co-lead agencies look forward to continue cooperation with region on actions to benefit ESA-listed species, such as those described by NMFS in its Columbia Basin Partnership Task Force. Finally, alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the 2018 EIS from NOAA and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so.
6605	8	Charles Tracy	Pacific Fishery Management Council	1. The DEIS does not incorporate the Councils scoping recommendations. Despite the Council having made extensive recommendations on DEIS scoping (enclosed, PFMC 2016), many of our comments are not incorporated in the DEIS. Among these, the Council called for an equitable analysis of actions that could lead to the recovery of ESA-listed stocks and restore Columbia River salmon populations to sustainable, harvestable levels. The Council also called for emergency response water temperature strategies and measures to improve passage and migration. These are further described below.	NEPA requires agencies to consider the significant environmental consequences of their proposed actions and inform the public about decisions being made. NEPA also requires that the agencies look at a reasonable range of alternatives that can meet the purpose and need of the action. To meet this requirement, after evaluating scoping comments from the public, the co-lead agencies collaborated with Cooperating Agencies in teams of technical experts through several iterations to create 12 alternatives that could meet the CRSO EIS Purpose and Need Statement: first, eight single objective alternatives, and then four multiple objective (MO) alternatives. The MOs were determined to be more efficient and reasonable, as the MOs were composed of combinations of measures from the single objective alternatives. The Draft EIS considered the environmental consequences of the range of alternatives and disclosed to the public those consequences. The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The co-lead agencies do not have authority to regulate harvest, which is the purview of tribal, state and other federal (i.e. NMFS) agencies, and an analysis of sustainable, harvestable levels is outside the scope of this EIS. Chapters 2 and 8 of the EIS describe the actions the agencies are taking to address water temperature, and Sections 3.4 and 7.3 discuss the effects of the CRSO EIS alternatives on water temperature.
6605	9	Charles Tracy	Pacific Fishery Management Council	2. The DEIS lacks an anadromous fish-focused alternative in its range of alternatives. The CRSO DEIS did not include a set of configurations and operational measures across the spectrum, as recommended by the Council during DEIS scoping, and as ordered by the 2016 U.S. Court decision, to ensure equitable treatment of anadromous fish-focused priorities, alongside other DEIS priorities. An anadromous fish-focused alternative would demonstrate the full potential for recovery and increased productivity possible with CRSO modifications that would likely include restoring spawning and rearing habitats in the Snake River and improved fish passage at all Federal Columbia River Power System (FCRPS) dams, but without additional measures to benefit power generation, water supply, and water management that adversely affect salmon and EFH. Such an alternative could include measures that reconnect and restore hundreds of miles of fish habitat throughout the CRS to improve spawning, rearing, passage, and natural migration. This would Page 4 likely include a combination of breaching the lower Snake River dams and high spill to 125 percent total dissolved gas (TDG) at the eight FCRPS dams. No such alternative was presented in the DEIS. In fact, the proposed alternatives are biased toward power generation and include measures that simultaneously improve and reduce fish survival.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. For additional information on the alternatives development, see Chapter 2 and Appendix A, which explains why single-objective alternatives were not carried forward for detailed study in the EIS. The agencies disagree, however, that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For Power and Transmission, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. This potential alternative has not been evaluated for direct, indirect and cumulative effects to other resources. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
6605	10	Charles Tracy	Pacific Fishery Management Council	3. The DEIS analysis does not sufficiently account for the impacts of climate change or avoid and mitigate increased water temperatures. The DEIS states, Air temperature is projected to be warmer throughout Region C (Section 4.1.2.1). Warmer air temperature combined with projected reduced summer and fall flow volume (Section 4.1.2.4) will likely lead to increased riverine and reservoir surface water temperature. Periods of higher temperature are projected to occur earlier in the year and last for longer durations than historically. Under the CRSO operations of the no action alternative, there are 257 temperature exceedance events annually. Under climate change predictions, reduced snowpack, and increased water temperatures and lower summer discharges, the frequency of cumulative daily temperature exceedance events will likely increase. The DEIS states the preferred alternative will result in additional exceedances of state water quality standards for temperature (68F). Temperature exceedances are expected to occur between 57 to 71 days, at each of the four Columbia River dams, for a total of 265 exceedance events. The DEIS also states that water temperature violations would occur more frequently during years when river flows are lower than normal and summer ambient temperatures are higher. The DEIS states, Historical water temperatures have already approached lethal limits for adult steelhead in the upper Snake and middle Columbia Rivers (Wade et. al 2013). Thus, even minor increases in thermal exposure put some of these populations above lethal limits. This is likely to occur with regularity as the effects of climate change persist in the Columbia Basin. The cumulative effect of increased water temperature is not adequately described in the DEIS, and can be anticipated to result in sub-lethal effects (compromised fitness) or direct lethal mortality. The preferred alternative did not analyze the effects of increased water temperature on fish populations, particularly the effects caused by climate change.	The analysis of MO3, which includes breaching the four lower Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at the resolution required (river vs. global or regional scale) at this time. Therefore, it was not possible to reliably model water temperature changes under climate change for incorporation to either of the fish models. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature and anadromous fish. These analyses are documented in Section 4.2.3 for the MO Alternatives and Section 7.8.4 for the Preferred Alternative. A thorough discussion of cumulative impacts from climate change is provided in Chapter 4 for the MO Alternatives and Chapter 7 for the Preferred Alternative. Overall, the Preferred Alternative is expected to result in benefits to anadromous salmon and steelhead. The analysis in Section 7.8.4 recognizes that some of the benefits to fish from the Preferred Alternative could be offset by the effects of climate change.

6605	11	Charles Tracy	Pacific Fishery Management Council	Furthermore, the DEIS does not include a thermal emergency contingency plan. The DEIS must anticipate thermal emergencies and provide a plan to mitigate such events. The Councils DEIS Scoping comments recommended the DEIS contain a thermal emergency contingency plan and offered sufficient detail for such a plan (see enclosed DEIS scoping letter).	The EIS analyzes the effects of operations, maintenance, and configuration of the CRS projects. The EIS evaluates multiple alternative ways of meeting the Purpose and Need Statement and a set of objectives for this federal action. The alternatives and analysis metrics, such as temperatures in different water year types, were developed for this purpose. Scenarios such as a "thermal emergency" in a specific year would be addressed through adaptive management as discussed in Appendix R. The co-lead agencies would utilize the Regional Forum, including the Technical Management Team, to address any emergency situations that arise that impact fish.
6605	12	Charles Tracy	Pacific Fishery Management Council	4. The DEIS does not include an equitable economic analysis of recreational, commercial, and tribal fisheries. The socioeconomic elements of the DEIS fail to address or employ widely accepted professional standards to ensure a thorough, objective and transparent evaluation of the DEIS alternatives. These standards are defined in court interpretations of the National Environmental Policy Act, the Corps guidance documents for socioeconomic analyses, and other standards. Consequently, there are severe, systemic gaps in the socioeconomic analyses of the DEIS. The DEIS fails to: Page 5 Make use of all the available socioeconomic information that is relevant, accurate, and reliable. Make a substantial, objective effort at studying, analyzing, and evaluating all the socioeconomic issues relevant to the actions considered. Account fully for the socioeconomic importance of ecosystems and ecological risks. Consider equally both effects that are monetized and effects that are not monetized. Examine the multiple socioeconomic consequences of the preferred alternative and other alternatives. Fully disclose all relevant information, and provide full transparency to the decisionmaking process, to enable the public and decision makers to understand the rationale for selecting the preferred alternative.	Chapter 7, Preferred Alternative, describes the process to select the Preferred Alternative. Socioeconomic effects from all of the alternatives are discussed throughout Chapters 3 and 7. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. That the effects of the alternatives on certain resources are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. The analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of Sections throughout the document. The Fisheries Section 3.15 as well as Section 3.17, in particular, include discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries Section 3.15.2.1, which includes Sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries. It is important to note that the EIS has undergone a third party neutral Independent Expert Peer Review on the tools used (including the economic models), as well as the assumptions and conclusions in the EIS.
6605	13	Charles Tracy	Pacific Fishery Management Council	The DEIS reports current gross domestic product (GDP) and full-time equivalent (FTE) fishery values for Oregon and Washington. Those numbers reflect the current state and value of salmon fisheries in Oregon and Washington, which are operating under a constraining set of rules that severely limits harvest. Given that other sections of the CRSO DEIS evaluate alternative futures, it is equally warranted to scale fishery economic values to that of a future with healthy salmon populations and what that would mean to the fisheries GDP and FTEs of the states. The Council anticipates that the increased employment and economic value would be substantial.	The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries (which the co-lead agencies have no role in), the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
6605	14	Charles Tracy	Pacific Fishery Management Council	Furthermore, the DEIS does not provide an equitable economic analysis of fisheries as a commodity. Hatchery contributions in the region are significant, but are not considered in the analysis. Both ocean and in-river fisheries that depend on the health of Columbia River salmon stocks provide millions of dollars in economic activity annually. From 2012-2015, Gislason et al. (2017) estimated that commercial and recreational salmon fishing accounted for an annual average of $1,996 million in GDP and supported 26,700 FTE jobs in the U.S. economy	Hatchery contributions are considered in the analysis. As described in Section 3.5, the co-lead agencies anticipate that changes in hatchery funding may occur as needs and obligations shift. The co-lead agencies do not anticipate that hatchery operations would be shuttered. As noted in Section 3.5, the co-lead agencies also recognize that there would be transitional needs that would be addressed in the additional mitigation measures for MO3 discussed in Chapter 5. Additionally, the Bonneville F&W Program funding for offsite mitigation projects in the Snake River Basin, implemented by local, state, Tribal, and Federal entities, would be reviewed, and potentially adjusted. Any changes of this nature would be implemented over time as the effectiveness of dam breaching is observed and would be done in consultation with fish and wildlife managers, regulatory agencies, and the Northwest Power and Conservation Council. Consistent with this, offsite mitigation projects for the other CRS dams would be reviewed and could be adjusted as operations change over time. Proposed project modifications would be coordinated with project sponsors and regional stakeholders to determine appropriate funding levels." Although Bonneville's funding of the Lower Snake River Compensation Plan hatcheries would no longer be authorized, remaining fish hatcheries would continue to produce fish and other Federal or state entities may continue funding the hatcheries. The EIS provides an evaluation of recreation (Section 3.11) and commercial fisheries and passive use values (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other areas would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. For MO1, MO2, MO4, and the Preferred Alternative, the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
6605	15	Charles Tracy	Pacific Fishery Management Council	Furthermore, recreational fishing is combined with other recreational activities into a single metric in the DEIS socioeconomic analysis of recreational use, and thus provides no measure of the economic impacts of different alternatives on recreational fishing. For the states with fisheries most impacted by CRSO operations, recreational angling for salmon accounted for an annual average $238 million in GDP and 3,160 FTE (Washington) and $173 million in GDP and 2,850 FTE (Oregon) (Gislason et al. 2017).	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. That the effects of the alternatives on certain resources are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. For MO1, MO2, MO4, and the Preferred Alternative (PA), the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the PA and MO4 (i.e., models show either beneficial or adverse effects on anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6605	16	Charles Tracy	Pacific Fishery Management Council	Likewise, the DEIS lacks an economic analysis of river and ocean commercial fisheries and tribal fisheries. Commercial salmon harvest accounted for an annual average $241 million in GDP and 3,090 FTE (Washington) and $55 million in GDP and 910 FTE (Oregon) (Gislason et al. 2017).	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of Sections throughout the document. The Fisheries Section 3.15 as well as Section 3.17, in particular, include discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries Section 3.15.2.1, which includes Sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries.
6605	17	Charles Tracy	Pacific Fishery Management Council	Beyond economic activity, salmon are profoundly important for the native peoples of the Northwest. As co-managers of the salmon resource, tribal interests must be an integral part of this discussion.	Tribal input, concerns, and interests were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7).
6605	18	Charles Tracy	Pacific Fishery Management Council	As stated previously, Council fisheries can be further constrained by listed species, depending on the actions proposed in the alternatives. Given the significant contributions of commercial, Page 6 recreational and tribal fisheries to regional economies, a fishery-specific economic analysis should be given equal weight with other commodity-specific analyses in the DEIS.	Chapter 7, Preferred Alternative, describes the process to select the Preferred Alternative. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of Sections throughout the document. The Fisheries Section 3.15 as well as Section 3.17, in particular, include discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries Section 3.15.2.1, which includes Sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries.
6605	19	Charles Tracy	Pacific Fishery Management Council	5. The DEIS alternatives analysis is insufficient in assessing the benefits of configurations and operations that restore or improve EFH for salmonids. The Council has long supported the Northwest Power and Conservation Councils (NPCC) Fish and Wildlife Program goals and objectives for listed and unlisted populations. The NPCC recovery goal for ESA-listed Snake River and upper Columbia River salmonids is a smolt-toadult return (SAR) rate of 2-6 percent, with an average of 4 percent. Below two percent, the population is at risk of decline. The NPCC objectives for unlisted populations or ESA-listed populations downstream of the Snake River and Upper Columbia River basins are to significantly improve the smolt-to-adult return rates (SARs) for Columbia River Basin salmon and steelhead, resulting in productivity well into the range of positive population replacement.	It should be noted that the 2-6% Smolt-to-Adult return (SAR) target referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the analysis of the Preferred Alternative, the co-lead agencies believe their actions will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To clarify, a point made in this comment, it is SARs below 1.0% rather than 2.0% that depending on the combination of SARs and freshwater productivity can lead to declines in populations. SARS above 2.0% like those predicted by the CSS model to result from the Preferred Alternative meet the lower end of the Council's SAR goals for rebuilding stocks. These improvements will apply to all stocks in the Columbia Basin, whether they are listed under the ESA or not.
6605	20	Charles Tracy	Pacific Fishery Management Council	The DEIS used two analytical models (the Northwest Fisheries Science Center [NWFSC] life cycle model [LCM] and Comparative Survival Study [CSS] model) for estimating fish survival under the alternatives (Figure 1). However, only four evolutionarily significant units were analyzed quantitatively; the following comments focused on the Snake River spring/summer Chinook evolutionarily significant unit for illustrative purposes. The CSS models accounts for the effects of powerhouse encounter rates, spill, water transit time, migration timing, and ocean conditions on juvenile survival (latent mortality), while the LCM model assumes there is little effect of the outmigration experience (other than estuary arrival time) on ocean survival and primarily attributes survival to ocean conditions. The disparity between the models underscores the shortcomings of the DEIS analysis. Nevertheless, the models generally agree that MO3 is best for fish, and that the preferred alternative is similar (LCM) or slightly better (CSS) than the No Action Alternative; however, there is there is so little variation in the LCM results (without assuming decreases in latent mortality) that they could be described as functionally the same. These results informed the Councils review of the alternatives, which is focused on the preferred alternative and on alternatives that provide substantial benefits to salmon (MO3 and MO4). Page 7 Figure 1. LCM1 and CSS model results2 of predicted SAR for Snake River juvenile Chinook for DEIS alternatives. The LCM results displayed assume 0% decrease in latent mortality	The co-lead agencies understand and acknowledge that model estimates for MO3, the alternative that includes the dam breaching measure, showed the greatest predicted potential Smolt-to-Adult returns (SARs) for Snake River salmon and steelhead among the alternatives, as well as other effects to species in both the upper and lower Columbia River. The purpose of the analysis in the EIS is not limited to which alternative benefits salmon the most. The EIS analysis provides analysis of multiple objectives and resources of the Columbia River System including flood risk management, water supply, hydropower generation, fish and wildlife conservation (including a variety of other species than salmon and steelhead), navigation, cultural resources, recreation and other environmental and socioeconomic resources. In addition, the EIS seeks to identify a Preferred Alternative that achieves a reasonable balance of multiple river resource needs and co-lead agency mission requirements. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6605	21	Charles Tracy	Pacific Fishery Management Council	MO3 (breach of the lower Snake River dams) The DEIS concludes that MO3 will have long-term beneficial effects for juveniles of all anadromous fish stocks, and major increases in Snake River fall Chinook spawning habitat. The DEIS also concludes long-term benefits from MO3 for anadromous adults in the Lower Snake and Columbia Rivers. MO3 is an aggressive reconfiguration of long-standing structure and operations that would improve conditions for migration and full life-cycle survival of anadromous species in the Columbia River. It is the only alternative that both models predict as an improvement over the no action alternative. MO3 consistently achieves SAR levels that lead to recovery; however, neither model accounts for the multitude of EFH benefits of a naturallyfunctioning river on salmon populations such as Snake River fall Chinook and coho salmon, or potential reductions in predation from non-native warm water fish species. 1 The footnote from Table 7-25 states in full: 1 / NMFS LCM does not factor latent mortality due to the System into the SARs or abundance outputs. For discussion purposes, potential decreases in latent mortality of 10 percent, 25 percent, and 50 percent are shown. The value for 0 percent is the actual model output, the 10 percent, 25 percent, and 50 percent values represent scenarios of what SARs or abundance hypothetically could be under the increased ocean survival scenario if changes in the alternative were to decrease latent mortality by that much. 2 The data for the PA- Preferred Alternative and the NAA- No Action Alternative are in Chapter 7, table 7-27 page 7- 102. The data for the other Multi-Objective Alternatives are in Appendix E, Table 3-22 page E-3-21. Page 8 Key habitat benefits that were not quantitatively analyzed in the DEIS are: Restoring approximately 140 river miles of spawning and rearing habitat currently inundated by the four lower Snake river reservoirs, with potential increase of up to 70 percent in spawning habitat for fall Chinook salmon (USACE 2002a) Decreased summer and early fall average daily water temperatures through the lower Snake river and possibly into the lower Columbia river and downstream of McNary Dam Restoration of natural riverine habitat from its current reservoir habitat, which would reduce non-native predatory fish such as smallmouth bass and walleye, and favor native species that co-evolved (i.e., salmon, steelhead, white sturgeon, Pacific lamprey, native trout) Major long-term benefits for ecosystem recovery, including wetlands, floodplains, vegetation, and wildlife that collectively benefit fish These habitat benefits can lead to improved survival of endangered fish stocks, which could have additional downstream effects, including potential delisting.	It is correct that neither the NMFS or CSS Life Cycle model included expanded spawner capacity in their modeling. There is considerable uncertainty around expectations for expanded spawning areas under MO3, the alternative that includes the measure to breach the lower Snake River dams. In the pre-impoundment era before the construction of Ice Harbor dam, most Snake River fall Chinook spawning occurred in the tributaries and middle/upper Snake upstream of Lower Granite (Groves and Chandler 1999). Scour from ice in the winter and relatively high water temperatures during fall (compared to the upper Columbia) were believed to be limiting factors. It is not known if ice formation would be a contemporary issue below Hells Canyon, and there is some doubt whether adequate gravels would be available in the lower Snake River. However, temperatures would be expected to cool earlier in fall. Groves, P. A., & Chandler, J. A. (1999). Spawning habitat used by fall Chinook salmon in the Snake River. North American Journal of Fisheries Management, 19(4), 912-922. For the 2000 Biological Opinion, NOAA proposed estimating free-flowing Snake River survival rates by estimating survival rates of PIT-tagged smolts from both the Salmon River trap to the Lower Granite bypass and from the Snake River trap (at the head of Lower Granite Reservoir) to the Lower Granite bypass. The per-kilometer survival rate of the free-flowing portion of the Snake River could be inferred from the difference between these two trap-to-dam estimates (Ferguson et al (2004). For the CRSO EIS, NMFS used a similar method of estimating free-flowing survivals and travel times with their COMPASS model. PIT-based monitoring efforts have occurred at 20-plus additional hatchery and wild-trap locations in the Snake and upper Columbia since the 2000 BiOp. In the appendix, NMFS carries out a sensitivity analysis for the choice of upstream trap location by comparing free-flowing survival rates estimates from the Grande Ronde, Salmon, and Imnaha traps to Lower Granite Dam to represent dam breach conditions under a dam breaching scenario. There is a wide variance in per-kilometer travel times and survival rates to Lower Granite Dam among all of the possible hatchery release sites and screw trap locations upstream of Lower Granite Dam. The river conditions and migration behavior of fish in tributaries to the Snake River is much less representative of river conditions we expect in the lower Snake River following dam breaching than are the river conditions in the free-flowing Snake River between the confluence of the Clearwater River and the confluence of the Salmon River. NMFS selected the three locations because each trap location was low in the tributary and are very close to the mainstem Snake River; we expect that reach of the free-flowing Snake to be very similar to what the breached lower Snake would look like in MO3. Traps further up in the tributaries are likely to tag more parr while these three traps tend to intercept mostly smolt-aged fish which arrive at Lower Granite without further rearing behavior. Yet it does appear that some fish in the Grande Ronde (GRN) and Imnaha (IMN) data exhibit parr-like behavior, especially in early April. This is a major contributor to why the GRN-IMN model predicts slower migration and lower survival in MO3 than the other calibrations, and the reason for why it was placed into the appendix. The Salmon River trap-to-Lower Granite reservoir free-flowing survival rate is used as a representative yearling Chinook population for the main text of the MO3 analysis. In response to the comment "outside the range of the data so the model is useless," this criticism can only apply to the Snake (SNK) calibration. Yes, MO3 is outside the range of the calibration data for the SNK calibration, as is noted in the Draft EIS text. The calibration between the Snake River Trap and Lower Granite Dam was just a "throwaway" calibration used to get at the GRN-IMN and Salmon (SAL) calibrations, and was not used in any prospective model runs for the CRSO EIS. However, the SAL and GRN-IMN calibrations are not outside the range of the calibration data when used for MO3. Flow, water velocity and temperature are all comparable between the free-flowing reaches of the Snake River used for calibration and the breached lower Snake dams in MO3.
6605	22	Charles Tracy	Pacific Fishery Management Council	MO4 (spring-summer spill to 125 percent TDG at all eight FCRPS projects) MO4 provides for spring-summer spill to 125 percent TDG at all eight FCRPS projects and would improve EFH conditions and salmon survival (including juvenile survival, ocean survival and smolt-to-adult survival) for most fish in the Columbia River system. In addition, it is expected to reduce juvenile passage delays and result in increased productivity of harvestable stocks.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO4. However, the Preferred Alternative also meets certain objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. MO4, by contrast, has significant regional economic and environmental impacts, and meets only a subset of the EIS objectives. Thus, the co-lead agencies did not recommend MO4 because the Preferred Alternative is more likely to satisfy multiple and, at times, conflicting legal requirements for a complex system.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6605	23	Charles Tracy	Pacific Fishery Management Council	6. The DEIS preferred alternative is not sufficiently improved over the no action alternative and, therefore, fails to meet a number of regional requirements, goals and objectives for salmon. The DEIS fails to recognize that both models predict that the preferred alternative will not achieve the NPCC recovery goal for Snake River Chinook. In fact, relative to the no action alternative, the preferred alternative will not sufficiently improve survival enough to recover listed stocks or increase healthy and harvestable populations. The actual survival benefit of the Flex Spill Agreement, which is fundamental to the preferred alternative, may overestimate survival benefits due to higher nighttime powerhouse encounter rates that are not accounted for in DEIS modeling. The CSS analysis further indicates a high (63 percent) probability that the preferred alternative will fall below the minimum SAR (2 percent), the rate at which the population is at risk for decline (McCann et al 2019). This is particularly problematic during low water years, which are expected to occur with greater frequency as climate change continues to manifest in the region in the form of reduced snowpack, earlier spring discharge peaks, and warmer temperatures nearly annually.	Regarding meeting regional requirements, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other applicable laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The CSS model predicts that Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and with a median well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. Regarding the overestimation of benefits due to higher nighttime powerhouse passage: in practice, model estimates may not be an overestimate due to day vs. night passage differences because limitations on nighttime spill reductions are already in place through the adaptive management process and lessons learned from the 2019 flexible spill operation. These adjustments in the amount of night time spill were informed by state, Tribal, and Federal biologists with expertise in dam operations and their effects to fish passage. These examples of adaptive management will continue during post-ROD operations.
6605	24	Charles Tracy	Pacific Fishery Management Council	The preferred alternative includes several structural measures that further threaten salmon survival: High capacity turbines: The preferred alternative (and other alternatives) includes installation of new high-capacity turbines (termed fish-friendly in the DEIS) at several FCRPS dams which will increase powerhouse flow. These new turbines require higher water volume than existing turbines, and will divert a greater proportion of flow, and therefore fish, away from the spillways and toward the powerhouses. Powerhouse passage is associated with stress, injury, direct mortality and delayed mortality. The cumulative effect of high-capacity turbines installed at multiple dams will likely further reduce SARs. Given that the benefits to a fish passing via a high capacity turbine are yet unproven, it is impossible to determine if that benefit can compensate for the proven detriments of increased powerhouse encounters. Therefore, it is premature to install highcapacity turbines until scientifically vetted.	The co-lead agencies disagree the Improved Fish Passage turbines would adversely affect SARS. See Section 3.5 and Section 7.7.4 for additional information. The new John Day and Ice Harbor turbines will be designed to operate within the existing turbine operating range. McNary turbines will be designed with an increased range. Once installed, the new turbines will be tested and validated for fish survival. Although only the McNary turbines will be designed for an increased operating range, the overall level of spill at any given project is determined not by the individual turbine unit capacity but by overall project operations management decisions. These decisions will occur through the Regional Forum and guided by the Adaptive Management Plan. Adaptive management strategies will be used to assure no detrimental impact.
6605	25	Charles Tracy	Pacific Fishery Management Council	Structural measures: All but four of the twenty-two structural measures in the preferred alternative are either measures retained from the no action alternative or new measures developed to increase power production, increase water supply for municipal or irrigation, or to benefit lamprey. The only structural measures included in the preferred alternative to mitigate for reductions in salmonid survival are the Lower Granite Trap Modifications and the Bonneville Ladder Serpentine Weir Modifications. Both of these modifications have been reduced in scope to only include trap gate modifications, which will greatly reduce anticipated benefits. Taken as whole, the structural measures in the preferred alternative will have an overall adverse impact on salmonid survival as compared to those in the no action alternative.	Based on the information provided in the comment, it is not clear how the structural measures would have an adverse effect to salmonid survival. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is predicted to benefit salmon and steelhead. It also meets the other objectives for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
6605	26	Charles Tracy	Pacific Fishery Management Council	Removal of fish screens: Fish screens have played an active role in diverting smolts away from turbines. The preferred alternative proposes to remove fish screens at several dams, which could increase turbine passage and result in increased injury and mortality.	As described in the Section 7.6.2.22 titled Fewer Fish Screens, the fish screens would not be removed when the increased efficiency hydropower turbines would be installed at Ice Harbor, McNary, and John Day dams until the co-lead agencies collaborated with NMFS and USFWS to develop a Turbine Intake Bypass Screen Management and Future Strategy process to monitor success of the turbines and determine if and when it would best to remove fish screens at these projects.
6605	27	Charles Tracy	Pacific Fishery Management Council	For the reasons described above, the preferred alternative fails to meet regulatory requirements for the recovery of listed species under ESA and water temperature requirements of the Clean Water Act, and fails to meet regional goals of the NPCC (2014) and Columbia Basin Partnership Task Force (2019) for the recovery of ESA-listed salmonids and sustainable, harvestable abundances of salmonid populations in the Columbia Basin. Furthermore, the preferred alternative does not improve or restore ESA-designated critical habitat and MSA-designated EFH for salmon in the Basin.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple legal responsibilities, including compliance with Section 7 of the Endangered Species Act. Under Section 7(a)(2) of the ESA, the co-lead agencies must insure that any action authorized, funded, or carried out is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species. Section 7(a)(2) does not require the co-lead agencies to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is predicted to benefit salmon and steelhead. It also meets the other objectives for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Chapter 8 of the EIS demonstrates the agencies compliance with applicable laws, including the ESA, MSA and Northwest Power Act. The co-lead agencies look forward to continue cooperation with region on actions to benefit ESA-listed species, such as those described by NMFS in its Columbia Basin Partnership Task Force. Finally, alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the 2018 EIS from NOAA and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so.
6609	1	Christina St. Germaine	The Clearwater County Economic Development team (CCED)	We recognize the CRSO DEIS process includes a response to The Opinion and Order from US District Court for the District of Oregon, which states the EIS should evaluate how to ensure that the prospective management of the CRS is not likely to jeopardize the continued existence of any endangered or threatened species We also recognize that the CRSO process, within the framework of the National Environmental Policy Act, looks to identify broad-based environmental and socio-economic impacts associated with the proposed alternatives. However, we do not find in the CRSO DEIA any analysis of socio-economic impacts from proposed actions. We cannot support the CRSO DEIS because both direct and indirect economic impacts of its proposed actions on regional economies are not considered, which are as follows: Clearwater County is home to Dworshak Reservoir, the Dworshak National Fish Hatchery and Clearwater Hatchery provide direct local economic value through a number of avenues: federal jobs (USACE, USFWS), state jobs (ID Fish & Game, ID Parks & Rec), commercial vendors (licensed outfitter-guides, campground operations); and indirectly from the hospitality industry (hotels, eating establishments and retail). According to ID Fish & Game angler surveys, steelhead fishing contributes $ 31,677,943 (inflation adjusted) annually in Clearwater River communities; and, throughout the region $ 80,815,718. Fishing on Dworshak Reservoir contributes $4,614,444 to the local economy. The Idaho Department of Labor Regional Economist recently provided multipliers of both jobs and income tied to steelhead fishing in Clearwater County: Jobs Average Earnings Job Multiplier Income Multiplier Outfitters & Guides 24 $23,221 1.54 1.70 Accommodation 55 $18,448 1.49 1.73 Restaurants & Bars 131 $14,692 1.33 1.63 Sporting Goods Stores 37 $35,831 1.55 1.76	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial, although quantitative impacts from fish modeling results are limited. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
6609	2	Christina St. Germaine	The Clearwater County Economic Development team (CCED)	The importance of angler spending cannot be understated in the Clearwater County economy. We do not understand why the CRSO DEIS does not address the economic impacts of its proposed actions on local and regional economies.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. For MO1, MO2, MO4, and the Preferred Alternative (PA), the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the PA and MO4 (i.e., models show either beneficial or adverse effects on anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term.
6609	3	Christina St. Germaine	The Clearwater County Economic Development team (CCED)	The CRSO DEIS suggests proactive coordination with Libby and Hungry Horse Reservoirs related to drawdowns and resident fish impacts but no such concern given to the Dworshak community. The Dworshak community has aggressively, over the past decade, marketed the bass and kokanee fishery in Dworshak while still maintaining the importance of the resident fish well-being. In fact, the first and second largest record smallmouth bass in Idaho were caught in Dworshak. Since, as previously noted, angler spending is a valued component in Clearwater Countys economy, why are resident fisheries not considered equally throughout the CRSO network?	The Walla Walla District leadership will continue active communication with stakeholders regarding Dworshak operations under the Preferred Alternative. As Dworshak operations are consistent with the No Action Alternative, there were no additional effects discussed in the Preferred Alternative analysis (Chapter 7). The Preferred Alternative analysis indicate the elevations would be very similar to the No Action Alternative by the time smallmouth bass would begin spawning in April or May and remain similar to the No Action Alternative through the summer and fall. Figure 7-13 illustrates the hydrograph in dry, average, and wet years. In this figure the No Action and Preferred Alternative hydrographs are nearly identical in average and wet years during April through June, and in dry years the elevation would be higher than the No Action Alternative at times during these months. The deeper draft is seen in January, February, and partly into March, especially in the wet years, in which the elevation would be lower than the No Action Alternative for a particular date in those months; in other words the reservoir would draft faster and earlier than the No Action Alternative, but it would not result in drawdowns any lower than the No Action Alternative at the lowest point. Effects to smallmouth bass are expected to be negligible. Boat ramps access would be the same as the No Action Alternative during months when they would be in use, and the summer drawdown would also be the same as the No Action Alternative, so mitigation would not be required under NEPA.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
6609	4	Christina St. Germaine	The Clearwater County Economic Development team (CCED)	The CRSO DEIS makes mention of a 2019-2021 Spill Operations Agreement. We learned from Corps staff that the Spill Operations Agreement is a negotiated spill regime between co-lead agencies, (Nez Perce Tribe and States of Oregon and Washington) for implementation in the Lower Snake River and Lower Columbia River Dams. It has been suggested that smolts historically made the downstream migration from the upper reaches of the Clearwater River system to the ocean in days and that with the slack water pools the trip takes months.	Federal, state and Tribal partners came together to develop an agreement on a key component of operating Federal dams in the Columbia River Basin. Parties to the agreement have aligned on a flexible spring spill operation premised on achieving improved salmon survival while also managing costs in hydropower generation and maintaining operational feasibility: (https://www.bpa.gov/efw/FishWildlife/SpillOperationAgreement/Pages/default.aspx) Average travel time through seven of the eight reservoirs and eight dams is presented in the CRSO EIS for each alternative for those species that could be modeled. For Snake River spring/summer Chinook, travel time under the Preferred Alternative is estimated at 15 days, one day fewer than the No Action Alternative.
6609	5	Christina St. Germaine	The Clearwater County Economic Development team (CCED)	We support and applaud the predator control measures: The measures proposed in the CRSO DEIS to reduce predation on downstream anadromous smolts. We support these predator control measures and encourage an aggressive approach to reducing avian predation of anadromous smolts.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
6609	6	Christina St. Germaine	The Clearwater County Economic Development team (CCED)	We applaud efforts that will increase flow in the pools enabling swifter migration of smolts through the CRSO hydro system.	Thank you for your comment.
6609	7	Christina St. Germaine	The Clearwater County Economic Development team (CCED)	The CRSO DEIS mentions a Zero Generation Opportunity, which would allow flow through dams without electricity generation. The proposal would extend the Zero Generation Opportunity from mid Dec Feb to Oct 15 Feb 28, when power markets warrant and river conditions make it feasible. The CRSO DEIS also states that a slightly deeper Dworshak would increase water flow through turbines Jan March with a focus on hydropower generation because the power demand markets are higher in winter across the CRSO. It seems the Dworshak water is being used for power generation to enable the Zero Generation Opportunity in the lower Snake-Columbia system. Dworshak has been tapped for years to augment flows for out-migrating anadromous fish. We do not support the elements in Zero Generation Opportunity for the following reasons: The Zero Generation Opportunity seasonal extension seems contradictory to the statement of the regional demand for power being greater in the winter. The additional winter season hydro power generation being considered for upper CRSO system storage facilities seems unsubstantiated (i.e. Libby is also a storage facility and has more generating capacity than Dworshak).	The commenter may be conflating two different issues. Drafting Dworshak slightly deeper has the power benefits described in the EIS. Dworshak often fills too quickly in the spring and then has forced spill to meet flood risk management operations. Spill at Dworshak leads to high TDG in water entering the lower Snake River which could adversely impact anadromous fish. Drafting slightly deeper commensurate with the water supply forecast above Dworshak would reduce the incidence of forced spill and provide power benefits described in the EIS. Due to the sensitivity around refill for summer cooling water, the developed process would use a higher probability of refill than what is used at other headwater projects (Grand Coulee and Hungry Horse). As shown in Section 7.7, Figure 7-12 and Table 7-14 in the Draft EIS, this operation does not measurably affect the elevation at the beginning of April or the flow in April except around the highest 1% of water conditions when flood risk management is an issue. The Zero Generation Operations measure, which is include in the Preferred Alternative, allows the lower Snake River projects to reduce generation during night-time hours when loads are lower. This reduction in generation decreases the outflow on the project which allows for water to be stored in the reservoirs for use later in the morning during high winter load peaks. Increasing water flows from Dworshak during January to March with the Zero Generation Operations measure would allow for more peaking capability on the lower Snake projects to meet high winter load peaks.
6609	8	Christina St. Germaine	The Clearwater County Economic Development team (CCED)	In the slightly deeper Dworshak scenario the CRSO DEIS should consider the impact on resident fish. Bass spawning typically occurs when water temperatures hover around 60 degrees F, which in the Dworshak neighborhood is April May. Given lower water levels in spring and the CRSO EIS lack of inclusion of any climate change assessment on water availability, a slightly deeper Dworshak could have negative impacts on resident smallmouth bass, a highly valued recreational fishery and growing economic engine in Clearwater Countys economy. Additionally, the graphs in CRSO DEIS Figure 7-13 suggest the slightly deeper Dworshak would reach full pool the last week of June and the previously negotiated Dworshak drawdown for fish outmigration begins July 1, resulting in a 1 week full pool recreational opportunity. We have remained actively engaged with the Dworshak recreation program over the years and have kept up with the visitor data collected by the Corps at Dworshak. Recognizing the data collection methodologies have changed over the years, the trend demonstrates a very clear relationship between pool level and visitation. The figures below represent data from USACE Dworshak Reservoir visitor tracking in 1990 (no summer drawdown) and 2019 (summer drawdown). We do not support the slightly deeper Dworshak scenario for the following reasons: There is no consideration to the impact on resident fish and strong potential for negative impacts on resident smallmouth bass. There is no analysis of resident fishery impacts as a result of a slightly deeper Dworshak? The climate change has not been considered in the CRSO DEIS in regard to snowpack and water availability There are no funding resources allocated to Dworshak Reservoir to facilitate water access during the slightly deeper Dworshak levels (boat ramp extensions) for public safety. There are no additional funding resources committed to offset the known negative impacts summer time drawdown has on Dworshak recreation (dock improvements, on water destination facility expansion, campground improvements, OHV use area/camping improvements).	Figures 7-12 and 7-13 offer different ways to view the elevation hydrograph, but both figures indicate the elevations would be very similar to the No Action Alternative by the time smallmouth bass would begin spawning in April or May and remain similar to the No Action Alternative through the summer and fall. Figure 7-13 illustrates the hydrograph in dry, average, and wet years. In this figure the No Action and Preferred Alternative hydrographs are nearly identical in average and wet years during April through June, and in dry years the elevation would be higher than the No Action Alternative at times during these months. The deeper draft is seen in January, February, and partly into March, especially in the wet years, in which the elevation would be lower than the No Action Alternative for a particular date in those months; in other words the reservoir would draft faster and earlier than the No Action Alternative, but it would not result in drawdowns any lower than the No Action Alternative at the lowest point. Effects to smallmouth bass are expected to be negligible. Boat ramps access would be the same as the No Action Alternative during months when they would be in use, and the summer drawdown would also be the same as the No Action Alternative, so mitigation would not be required by NEPA. Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives.
6609	9	Christina St. Germaine	The Clearwater County Economic Development team (CCED)	In Clearwater County the economy and individual livelihoods are closely tied to the natural resources; natural resource management is a leading economic cluster. The jobs and wages associated with the government funded positions, the outfitters and guides who host anglers and the local hospitality businesses are intrinsically linked to the way our resources are managed. We request consideration of the impacts the CRSO EIS preferred alternative will have on the Clearwater County economy.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively.
6611	1	lochsalaughy@yahoo.com	N/A	Consider also that the Environmental Protection Administration, forced into action after 17 years by a Clean Water Act lawsuit, has once again prepared a working document leading to a TMDL for water temperature on the Columbia and Snake Rivers. As in its 2003 draft, EPA once again finds the source of increased water temperatures in these impaired water bodies is the reservoirs behind the dams. Now EPA also adds its estimate of temperature increases over time that will result from global warming. The only way the Lower Snake River Dams can meet water quality standards critical for SR salmon and steelhead is with the elimination of the pools behind the LSR dams.	EPA's temperature TMDL evaluates both natural and anthropogenic sources of heat in the Columbia and Snake rivers. The temperature TDML is a comprehensive analysis identifying all the sources of heating in the Columbia and Snake rivers, including the CRS dams and reservoirs. The EIS indicates that some CRS dams can lead to heating and cooling, while other CRS dams have little to no influence on the river temperatures. Regarding the lower Snake River dams, the EIS references historical temperatures in the lower Snake River basin prior to the construction of the lower Snake River facilities and the Hells Canyon Complex. This data shows that temperatures in the pre-dam, free-flowing lower Snake River often exceeded 68F (20C) in July and August and occasionally exceeded 25C. These measurements were taken near the mouth of the Snake River from 1955 to 1958. (Peery, C. A. and T. C. Bjornn. 2002. Water Temperatures and Passage of Adult Salmon and Steelhead in the Lower Snake River. Technical Report 02-1. U.S. Geological Survey, Idaho Cooperative Fish and Wildlife Research Unit, University of Idaho, Moscow, Idaho.) For information regarding the recently issued TMDL for temperature in the Columbia and lower Snake rivers, please see https://www.epa.gov/columbiariver/tmdl-temperature-columbia-and-lower-snake-rivers.
6611	2	lochsalaughy@yahoo.com	N/A	One more observation: In April 2016 NOAA Fisheries provided a biological opinion to the Federal Emergency Management Agency requiring FEMA in Oregon to provide greater protections for imperiled salmon, steelhead and yes, to Southern Resident Killer Whales. NOAAs BiOp states that these species. depend on healthy, functioning floodplain habitat. Altering the natural processes that allow habitat to form and recover from disturbances, such as floods, can affect multiple stages of the salmon life cycle and impede their survival and long-term recovery. Lets place the DEIS in context based on the decision Judge Michael Simon rendered on the operation of the FCRPS: a. More than 20 years ago, Judge Marsh admonished that the Federal Columbia River Power System cries out for a major overhaul. b. Judge Redden, urged the relevant consulting and action agencies to consider breaching one or more of the four dams on the Lower Snake River. however, the federal agencies have ignored these admonishments and have continued to focus essentially on the same approach to saving the listed speciesHydro-mitigation efforts that minimize the effect on hydropower generation operations. c. Judge Simon stated that for the past 20 years the federal action agencies have done their utmost to avoid considering the reasonable alternative of breaching, bypassing, or removing one or more of the Lower Snake River Dams. d. NOAA Fisheries has identified critical habitat necessary through the migratory corridor for the survival of endangered Snake River salmon and steelhead, including a waterway free of obstruction with water quantity and quality conditions and natural cover such as submerged and overhanging large wood, aquatic vegetation, large rocks and boulders, and side channels. e. In 2016 NOAA fisheries provided a biological opinion to the Federal Emergency Management Agency requiring FEMA in Oregon to provide greater protections for imperiled salmon, steelhead and Southern Resident Killer Whales. NOAAs BiOp states that these species. depend on healthy, functioning floodplain habitat. Altering the natural processes that allow habitat to form and recover from disturbances, such as floods, can affect multiple stages of the salmon life cycle and impede their survival and long-term recovery. The science of what is required for the recovery of threatened and endangered Snake River salmonids is clear. Idaho Congressman Mike Simpson encapsulated those requirements in just five words: The salmon need a river. He was referring to the series of four reservoirs that now define the lower Snake River. In 2019 Snake River threatened and endangered spring and summer Chinook salmon population returns were .006 per cent of their historical abundance. For fall Chinook the number was .011 percent; steelhead at .029 per cent; sockeye salmon at .0005 percent. The DEIS calls for a continuation of the status quo, a tweak here, a tuck there, clearly not enough to produce the average 4% SAR needed for fish recovery, just enough to keep the wild salmon and steelhead from going extinct. Maybe.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. It should be noted that the 4% average SAR target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
6620	1	lagergren@cs.com	N/A	Also old dams that need extensive work for repairs and need mitigation measures to protect Salmon require electricity for the work and thus will negate the positive contribution of the hydropower they may produce. It has been described for years that the cost benefit of the dams for producing electricity, and for the cost of keeping the dams for cargo transportation up to Lewiston is a decreasing or even a money-losing endeavor. It may be	As explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, MO3 (which includes breaching the four lower Snake River dams) would have a direct and substantial impact on the supply of Federal power to meet regional load requirements. Breaching the dams would reduce energy to meet regional load requirements, and reduce generating capacity (peaking capacity) to meet variability in loads. The four lower Snake River dams are among the most

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				cheaper to transport by truck or rail than to barge up the complicated dammed-up river. Lewistons and other communitys economy could benefit far more from a lucrative sport fishing industry IF wild Salmon numbers could be allowed to recover.	valuable projects in FCRPS. These dams provide over 1000 MW of carbon-free energy and up to 2000 MW of peaking capacity at certain times of the year. The dams also have unparalleled ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2200 MW of capability in certain months of the year. Access to barge transportation is the most cost effective means of accessing export markets for many of the grain producers in the Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS shows. Impacts to navigation from MO3, which includes the dam breach measure, along with community effects, are described in Section 3.10.3.5. Impacts to recreation are described in Section 3.11.3.5 for MO3.
6625	1	sjones@2ndhomes.com	N/A	1. The DEIS must include a comprehensive economic analysis of Idahos salmon sportfishery and its potential in the event of restored abundant wild salmon and steelhead returns. In 2019 anglers spent $750 million dollars in the state. In the Clearwater region in 2003, during a decent return year, salmon	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in tum, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. For MO1, MO2, MO4, and the Preferred Alternative (PA), the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the PA and MO4 (i.e., models show either beneficial or adverse effects on anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term.
6625	2	sjones@2ndhomes.com	N/A	2. MO3, the dam breaching alternative, is the only option that meets life-cycle survival criteria, achieves meaningful recovery, and minimizes the jeopardy of extinction. According to the scientific models from many agencies in the DEIS, only MO3 will lead to smolt-to-adult ratios (SARs) that meet regional goals. Averaging 4 adults returning for every 100 smolts migrating out (4% SAR), with a range of 2-6% SAR has been deemed necessary for recovery to sustained, harvestable abundance MO3 is the only alternative that adequately minimizes the risk of extinction for Snake River stocks as a baseline; something legally required of this DEIS.	It should be noted that the 2-6% SAR target referenced in this comment refers to the Northwest Power and Conservation Councils (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the Preferred Alternative analysis, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6625	3	sjones@2ndhomes.com	N/A	3. Alternative MO3 needs to include an accurate cost-benefit analysis of the four Lower Snake River dams, the power they generate and the does the market want the power? Purchasing replacement power on the open market would cost $11 million/year. This is $38 million/year cheaper than estimated LSRD maintenance and operation expenses and does not include benefits from reduced fish and wildlife and turbine rehab costs. Turbine replacements and maintenance in the next decade at the four dams will cost tens of millions of dollars a year	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Without adding replacement resources, the LOLP without the four lower Snake River dams increased to 13.9 percent above the 6.6% of the No Action Alternative and about the 5% standard set by the Council The cost range of these replacement resources would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $156 million and $417 million and the benefit-cost ratios are between 2.9 and 6.1. If the generation could be reliably replaced with short-term wholesale market purchases (see Table 3-170 of the Draft EIS), the lower bound for net benefits would fall to $57 million and the benefit-cost ratio would fall to 1.7. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1, the Headwater/Lower Snake Asset Class2 is forecast to have a 50-year levelized cost of generation3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant amortized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
6631	1	N/A	N/A	3. Culture-- the creation of the four dams and the reservoirs flooded 14,000 acres of indigenous homelands (34 ,000 acres, 700 sites according to the state of Washington where the dams are located), containing burial grounds, sacred gathering places, villages, artifacts, and accustomed sites for fishing, hunting, and gathering. While the executive summary views the removal of reservoirs as a negative in terms of this culture, I see it as a positive. As the dams are breached, native sites would need to be protected as they were with a breaching of the Wanapum Dam, so their artifacts are not washed away or compromised by looters. When the breaching and reservoir drawdown are complete, Native peoples can return to these sites to honor and retrieve a part of their history and culture that was lost when the dams were constructed	In the Draft EIS, Table 3-105, the co-lead agencies provide the estimated amount of acreage that would convert from inundated land to non-inundated land, estimated at 13,772 acres. For the purposes of the cultural resources impact analysis, the co-lead agencies rounded this number up to 14,000 acres. This estimate is based on GIS analysis of anticipated land mass areas to be exposed during the implementation of MO3. In Section 3.16.3.6 in the Draft EIS, the co-lead agencies provide an impact analysis to all identified cultural resources in the study area under MO3. On pages 3-1390 through 3-1391 in the Draft EIS, the co-lead agencies noted the exposure of Traditional Cultural Properties would allow a resumption of traditional uses that have not been possible since the dams were constructed and this is viewed as a beneficial effect. The Preferred Alternative identified in the Draft EIS did not include the measure to breach the four lower Snake River dams.
6631	2	N/A	N/A	5. Agriculture-There will be change and loss to families who farm the 47,000 acres along the Snake River. While I recognize this loss is substantial to those involved, I must weigh it against the 34,000 acres and 700 sites that will be restored to the Native peoples if the dams are breached. While our immigrant culture has been here for the past 200 years, Bative culture thrived along the river for at least 12,,000 years. It must be noted that there are 5 million other acres of farmland in Southeastern Washington, not impacted by dam breaching. Certainly agricultural losses must be mitigated. The CRSO indicates that these losses will be near Tri-Cities. The Tri-Cities is bounded not only by the Snake but by the much larger Columbia as well. It seems that it would make sense to study whether irrigation can be provided by the Columbia River itself if the Ice Harbor Dam is breached. A study in Washington indicates that lowering intake structures, increasing pumping capacity, and digging deeper wells can leave at least a third of the 47,000 acres intact. Other alternatives also need to be explored: could farmers be compensated for their loss through financial remuneration, by assisting them in moving to dryland agriculture, by offering them land and infrastructure at new locations. I do not say I do not see that the ways of mitigating agriculture have been fully studied or addressed in this CRSO.	In Region C (lower Snake River) and potentially Region D (mainstem Columbia River) around the confluence of the lower Snake River, the MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams will reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected. Additionally, transportation of farming goods would expect to move off river and on to rail or trucks, as there would be a complete loss of commercial navigation on the lower Snake River and could not be feasibly mitigated. All ports along the Snake River would lose access to the navigation channel. Some ports at the confluence or the Snake and Columbia River could dredge new channels to the Federal channel in the confluence (McNary reservoir) to maintain access. Private or public entities or businesses could take actions and/or build infrastructure to extend pumps or water supply access for water. Ports and farmers can likewise change their transportation modes or connect to the navigation system at a different point on the river. See Chapter 3 analyzes the social and economic effects of implementing a dam breaching alternative (MO3) and Chapter 5 for mitigation discussion. This EIS discusses engineering solutions (pipeline extensions for example) in Section 3.12.3 Environmental Consequences - Specifically under Region C under the MO3 alternative (see page 3-1267, line 3244 in the Draft EIS) and in Appendix N. The report which this EIS draws upon, as discussed, concluded that modifying the existing pump system was cost prohibitive. In Region C under the MO3 alternative this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres. This is discussed in Section 3.12.3 under Region C and the MO3 alternative. NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide mitigation for the effects to private infrastructure such as ports, irrigation pumps, wells, or private docks.
6631	3	N/A	N/A	7. Transportation-- Trucks, railroads, and barges are currently used to transport grain between Tri-Cities and Lewiston, a distance of 140 miles. Barge transport is safest, cheapest, and most reliable followed by rail and then trucking. The grain transported in 100 raill cars is equivaleny to the grain transported in a four barge transport on the River. Barge traffic has declined by 70% in the past 20 years; grain makes up 87% of the cargo still transported, which is taken to the Pacific coast to be exported overseas. Northeastern Washington and North Idaho grain growers rely on rail transport;	The volume of wheat on the river has declined, with variation, over the past 20 years, but steadied the past eight years. For evaluating effects, 2.4 million tons is used, which reflects the average over the past 10 years. Access to barge transportation is the most cost effective means of accessing export markets for many of the grain producers in the Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS described in Section 3.10.3.5. The EIS finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. The co-lead agencies lack the authority to invest in or mitigate for private infrastructure, such as rail lines.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Southeastern Washington growers reliy on rail and barges. There are already many rail-to-coast systems in place without the use of barges. Washington Grain Train provides a transport system from remote rural farmlands serving 2,500 members in Eastern Washington to International ports. Multi rail car loading facilities have been established in at least 22 Eastern Washington sites, allowing farmers to truck their grain short distances to rail transport. I see no mention of these resources or the role they might play in replacing barge transport in the Executive Summary. Both the dams and the rail systems are in need of infrastructure repair. In order to maintain barge traffic millions of dollars must be poured into restoration of the four aging dams. I believe this money would be better spent upgrading railroad infrastructure. Rail transport provides middle-ground option and has the advantage of being able to service remote farming communities both in northern and southern Eastern Washington. In our quest to reduce fossil fuel consumption to ameliorate climate change, rail that travels close to farm lands is the best option since trains are far more fuel efficient and leave substantially less of a carbon footprint than trucking. That is, we are going to need to expand railroad transport of goods and people in order to mitigate climate change, so our investment ought to go into the rail system. Again while loss of barging will bring an end to a family enterprise and local river culture, it will restore the natural historical river culture of fish and their Native American caretakers.	
6646	1	solomon.michelle@gmail.com	N/A	Scientists from the Fish Passage Center have stated that breaching all four of these dams would result in roughly 1 million adult Chinook salmon returning to the mouth of the Columbia River, providing significant relief for endangered Southern Resident orcas. As you know Chinook salmon are the orcas' primary food source from central California to the Salish Sea. And the Columbia Basin supports salmon runs that the orcas have relied on for centuries. Historically half of all the salmon returning to the Columbia Basin were bound for the Snake River. But after the river was dammed more than half a century ago, the wild salmon runs plummeted and left the orcas with fewer fish to eat. Despite the fish ladders and our current interim spill measures, dams continue to cause serious salmon declines by directly killing and preventing their migration. Breaching these dams will cut dam-caused mortality by at least 50%. What's more, these dams have flooded miles of spawning habitat, destroyed healthy riparian forests, and created lethal warm-water reservoirs.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by USFWS.
6646	2	solomon.michelle@gmail.com	N/A	With climate change, the number of days where temperatures will reach deadly levels are expected to increase. Independent research has stated that removing these four dams will help cool the river. By removing these dams, we'll also be increasing salmon access to more than 5,500 miles of free-flowing, climate-resilient, federally protected spawning habitat in northwest Oregon, southeast Washington and central Idaho.	Historically, water temperatures in the lower Snake River were warm (USGS 1960, 1961, 1964; Corps 2002a). Observed historic water temperatures show that average monthly water temperatures during July and August, in the 1950s, averaged 7 to 8 degrees Fahrenheit higher than today's conditions, while maximum daily differences were 10 to 12 degrees Fahrenheit higher. The differences observed in the lower Snake River today, as compared to historical conditions, are a result of the middle and upper Snake River reservoirs combined with the influence that Dworshak Dam operations. The EIS analysis shows that when breaching the four lower Snake River dams, nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. The models showed minor changes in the Columbia River under MO3, indicating that the operations of the CRS dams have a limited ability to reduce temperatures in the lower Columbia River. Summer water temperatures exiting the Snake River are typically 1 to 3 degrees Fahrenheit warmer than the receiving Columbia River temperatures. Even though the cold water released from Dworshak during the summer is less than 50 degree Fahrenheit, the volume of water released is less than one tenth of the flow in the Columbia River. Since the distance between the confluence of the Snake and Columbia Rivers is about 180 miles downstream from Dworshak, the impact on water temperatures is negligible. Regionally high air and water temperatures result in water quality standard exceedances that are beyond the ability of the CRS to cool. Overall the conclusion in the Draft EIS is that MO3 would be beneficial to anadromous fish for a number of reasons, but other objectives must also be considered in the selection of a Preferred Alternative. The four lower Snake River and four lower Columbia River dams are equipped with adult fish ladders which are safe and effective for passing adult fish upstream, and adult salmon and steelhead passage is generally considered good through the lower Snake and Columbia rivers. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change and, unfortunately, they have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. Therefore it was not possible to reliably model water temperature changes under climate change for incorporation to either of the fish models. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature and anadromous fish. These analyses are documented in Section 4.2.3 for the multiple objective alternatives and Section 7.8.4 for the Preferred Alternative. Overall, the Preferred Alternative is expected to result in benefits to anadromous salmon and steelhead. The analysis in Section 7.8.4 recognizes that some of the benefits to fish from the Preferred Alternative could be offset by the effects of climate change.
6647	1	treeder@portofkalama.com	N/A	2. The MO3 alternative does not meet the objectives identified in the Purpose and Need statement. Breaching the dams would not allow for operation of the Congressionally authorized purposes of maintaining and operating the four lower Snake River dams for navigation, hydropower, irrigation, and recreational benefits.	Thank you for your comment.
6647	2	treeder@portofkalama.com	N/A	3. The MO3 alternative would increase air pollutant emissions due to the increased greenhouse gas emissions from power generation and the shift away from river-based navigation to truck and rail that would follow. Breaching the dams would actually result in the addition of 1,251,000 tons of CO2 per year, which is a factor of 2.38 greater than what is included in the DEIS.	The comment that air pollutants and greenhouse gas emissions would increase under Multiple Objective Alternative 3 is consistent with the findings of the EIS. This comment describes the results of a recent Pacific Northwest Waterways Association report that, due to a variety of differing assumptions from the EIS, is not directly comparable to the EIS navigation analysis.
6647	3	treeder@portofkalama.com	N/A	4. The DEIS understates the harm to transportation that would be caused by dam breaching, particularly with regard to river navigation. The DEIS did consider the downriver grain shipments, which make up 62% of shipments on the Snake River, but did not include the remaining 38% of shipments. The economic impacts of the loss of the 38% of other shipments needs to be addressed. Furthermore, the use of barges on the river for movement of grain is very important. The Port of Kalama sees 400-500 barges per year just from the Snake River system. Maintenance of the dams is essential to maintaining barge traffic for the grain terminals and other industry and to maintain exports from inland ports.	In 2018, 72 percent of overall freight volume on the Lower Snake system traveled downriver, the majority of which (87 percent) was wheat and barley. As discussed in Section 3.10.2.1 of the Draft EIS, 28 percent of overall freight traveled upriver. In 2018, 25 percent of overall freight on the Lower Snake River was petroleum products that terminated below Ice Harbor Dam. These shipments do not utilize the Snake River locks and would not be directly affected by dam removal under MO3. This was unclear in some instances in the Draft EIS, and has been corrected and clarified in Section 3.10 and Appendix L. Other commodities that utilized the Snake River system included pulp and paper products (4 percent) as well as chemicals and iron/steel commodities (8.5 percent), some of which also terminate below Ice Harbor Dam. To the extent that these shipments utilize the Snake River locks and dams, they would be affected under MO3 by increased transportation costs. These potential effects are discussed qualitatively in Section 3.10.3.5.
6647	4	treeder@portofkalama.com	N/A	5. The salmon survival benefits associated with Alternative MO3 are uncertain, speculative, and subject to scientific dispute. Other rivers that are undammed are also experiencing reduced salmon survivability, such as the Fraser River among others. Therefore, there are other forces negatively impacting salmon overall. There is strong evidence to suggest that the downward trend of salmon survival is due in large part to other factors including ocean conditions, and avian and pinniped predation. The DEIS should be revised to address mortality assumptions and predictions used in the DEIS, as well as the evidence that other forces have a significant influence on salmonid survival.	The majority of a salmon's life is spent in the ocean. Therefore, the habitat, food, and predator conditions in the ocean will have a large influence on the proportion surviving to reproduce. When ocean conditions are good, the Columbia Basin enjoys large returns of salmon such as in 2014, for example, when nearly every ESU had record returns. However, when ocean conditions are poor as has been the case for the past several years, the number of adult salmon are much smaller. While none of the alternatives would affect ocean conditions, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of ocean conditions in the return of adult salmon and steelhead (Peterson et al. 2019). Among the objectives are improving passage conditions and survival of both juvenile and adult anadromous fish through the CRS. The more healthy juvenile salmon that enter the ocean, whether the conditions there are good or poor, the greater the returns to the Columbia Basin can be. The greater the success adults migrating up the Columbia and tributaries and spawning, more juvenile can be produced for the next generation. Under the Preferred Alternative, actions for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The co-lead agencies analyzed the effects of the operation, maintenance, and configuration of the CRS projects on resources affected by the CRS, including the potential to improve conditions for ESA-listed species. The co-lead agencies also looked at the cumulative effects of other actions, including harvest in Chapters 6 and 7 of the EIS. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm.
6657	1	N/A	N/A	In addition, there is no cost-benefit analysis of the removal of the four Lower Snake River dams and the power they generate. The cost of purchasing replacement power on the open market is much less that the estimated LSRD maintenance and operation expenses alone, which does not include benefits from reduced fish and wildlife and turbine rehabilitation costs which cost tens of millions of dollars a year. The benefits of a restored Lower Snake River corridor (140 river miles if the dams were breached) are not sufficiently described. Allowing spillover for fish is a start, but it does not adequately minimize the risk of extinction, which the presence of dams significantly increases.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $156 million and $417 million and the benefit-cost ratios are between 2.9 and 6.1. If the generation could be reliably replaced with short-term wholesale market purchases (see Table 3-170 of the Draft EIS), the lower bound for net benefits would fall to $57 million and the benefit-cost ratio would fall to 1.7. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation <Blockedhttps://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf> at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: Blockedhttps://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf <Blockedhttps://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf> and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
6657	2	N/A	N/A	This report underestimates the benefits of improving Idahos salmon fishery. The fishing industry is a huge draw for tourism, supporting guides, outfitters, and businesses in river towns throughout Idaho, which would positively impact the local economy. Outdoor recreation is a 2.3 billion-dollar industry in Idaho. In summary, the DEIS greatly minimizes the potential benefits of a restored Lower Snake River corridor.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial although quantitative impacts from fish modeling results are limited. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
6657	3	N/A	N/A	The argument that decreasing hydropower generation automatically means an increase is greenhouse gas is misleading. Natural gas does not have to be the alternative power source to decreasing hydropower generation. Cost of renewable energies is continuing to drop, and research has shown that these energy sources would provide tons of jobs and boost the economy. Reliance on energy sources that are not finite is a huge investment in our future, both for economic stability and environmental protection	Contrary to the comment about replacement power resources, the EIS did not exclusively examine natural gas. The EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council in their 7th Power Plan (7th Power Plan, pages 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission, Section 2.2. The EIS identifies natural gas as the conventional least-cost replacement portfolio as well as a portfolio of solar, demand response and storage as the least-cost zero-carbon portfolio. See draft EIS, Section 3.7.3.5 at pages 3-904-910. The EIS finds that under these portfolios greenhouse gas emissions increased. See draft EIS, Section 3.8.3.5 at pages 3-1009-1010. For the zero-carbon renewables portfolio, the increase in emissions is due to increased generation from existing fossil fuel power plants because new renewable resource like wind and solar are variable and not always available. The magnitude and timing of the reduction in hydropower generation would occur in particular times seasonally or daily (e.g., during peak demand) during which flexible resources would need to increase generation in order to maintain reliability (i.e., to meet the demand for power and avoid blackouts). In addition, the four lower Snake River dams play an important role in the regional power system, particularly in regards to the integration of renewable power sources, which, as described by the comment, are likely to increase in the future. See draft EIS, Section 3.7.3.1, Integration Services at page 3-832.
6659	1	John Francisco	Northwest Requirements Utilities (NRU)	Summary of Conclusions The co-lead agencies have conducted a robust process that fulfills the statutory and policy purposes of the National Environmental Policy Act (NEPA). NEPA does not dictate any particular policy outcomes and does not mandate particular results. Instead, it regulates the manner in which federal agencies arrive at their outcomes by simply providing the necessary process to ensure that federal agencies take a hard look at the environmental consequences of their actions. The CRSO process as envisioned and carried out by the lead agencies easily and clearly meets this threshold.	Thank you for your comment.
6659	2	John Francisco	Northwest Requirements Utilities (NRU)	The Preferred Alternative represents an objective and sustainable path that meets all objectives set by the lead agencies. In fact, the Preferred Alternative is the only alternative that meets all eight study objectives. The study objectives were formulated with extensive and substantive input from stakeholders. Stakeholders were given ample opportunity at the outset of the process for input to the lead agencies through oral, written and in-person comment opportunities. Four of the eight objectives specifically address improving fish stocks, including lamprey. The remaining objectives recognize the other vital resources provided by the CRS and recognize that increasing anadromous fish and lamprey populations at an untenable societal expense does not represent a balanced or holistic outcome. NRU supports the Preferred Alternative and urges the lead agencies to carry the Preferred Alternative forward to the final environmental impact statement. Mitigation for the Federal Columbia River Power System (FCRPS) is a goal shared by NRU members. NRU members contribute significantly to efforts to improve survival rates of anadromous fish. Mitigation costs currently comprise some 25% of our members wholesale rates and have historically been as high as 33%. Mitigation must be scientific, cost effective and have a nexus with FCRPS operations. We do have concerns with some elements of the Preferred Alternative. The Preferred Alternative primarily relies on increased spill over the dams to meet the objectives focused on increasing fish populations. The levels of spill defined in the Preferred Alternative have not been proven to benefit fish populations and estimates from the two models used in the analysis show disparate results when estimating increases in fish population related to the - 3 - spill assumptions from the Preferred Alternative. We make further comments on this topic and other topics in the following sections of these comments.	The co-lead agencies have used high-quality information and the best available science in the analysis of the alternatives included in the EIS. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies are committed to ongoing coordination with stakeholders through a variety of forums. In areas where we have appropriate authority, we will continue to be strong regional partners. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on the fish analysis in Section 7.7.4 for the Preferred Alternative, it will make a meaningful contribution towards recovery, but the Councils broad sense recovery goals are beyond the scope of this EIS which is limited to those effects associated with the operation and maintenance of the 14 CRS projects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
6659	3	John Francisco	Northwest Requirements Utilities (NRU)	Any new costs resulting from the EIS must be equitably allocated and cannot be borne exclusively by BPA/public power. Cost responsibility for mitigation efforts should equitably align with public benefits. Doing so recognizes the regions shared stake in these efforts and the diverse benefits provided to multiple users of the CRS.	The financial responsibility for fish mitigation is not solely allocated to Bonneville's power ratepayers as the comment suggests. Fish mitigation costs are assigned to each authorized project purpose based on each purposes overall share of project costs, as determined by the cost allocation, by recovering those costs through power rates. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Congress also granted Bonneville discretion to fund the power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992, in some situations, including the Columbia River Fish Mitigation program. (Energy Policy Act of 1992, Pub. L. No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)). Bonneville generally does not, however, directly pay for the capital costs of fish mitigation structures; instead, it reimburses the U.S. Treasury for the power share of appropriations used to construct the structure. As described in Section 3.19 of the EIS and Appendix Q, funding to operate the system comes through multiple mechanisms, including Federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. For joint related costs, including funding for fish and wildlife mitigation actions, the Corps and Reclamation receive annual congressional appropriations to fund most, if not all, capital investments. Bonneville reimburses the U.S. Treasury for the power share of these appropriations. Once the investment is in place, Bonneville will typically direct fund the power share of the operations and maintenance costs associated with the facility. In addition to congressional appropriations for fish and wildlife and costs directly funded to Corps and Reclamation by Bonneville, the Bonneville Fish and Wildlife Program (which is separate and distinct from direct funding described above) funds hundreds of projects each year to mitigate the impacts of the Federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the FCRPS. Bonneville uses its authority under 16 U.S.C. 839b(h)(10)(A), to make expenditures to implement its Fish and Wildlife Program, which is funded by Bonneville's electricity ratepayers as part of the rates Bonneville sets to recover its costs. These expenditures provide systemwide funding for actions that also mitigate for the non-power purposes of the CRS, so Bonneville recoups the non-power share of those expenditures from the U.S. Treasury as credit, as required under 16 U.S.C. 839b(h)(10)(C). Bonneville's Fish and Wildlife Program expenditures incurred mitigating the CRS operations identified in the final EIS and adopted in Bonneville's Mitigation Action Plan would continue to be allocated and borne as provided by existing laws governing the FCRPS and the long-standing accounting procedures used to implement them.
6659	4	John Francisco	Northwest Requirements Utilities (NRU)	Fish and Wildlife Two models have been relied on in the study to predict the effects of alternative hydroelectric system operations on Columbia and Snake River salmon and steelhead populations: the COMPASS model used by NOAA Fisheries and the Comparative Survival Study (CSS) model used by the Fish Passage Center. Each model relies on different inputs and assumptions. The two models often align but diverge on expected smolt to adult returns (SAR). The CSS model predicts much higher adult salmon returns associated with increased spill levels and/or dam breaching than the COMPASS model. The choice to prioritize one model over the other in the study is not validation of one model over another. The divergent results of two widely accepted models demonstrates the uncertainty of river operations science. Given this level of uncertainty, it is critical for the federal agencies to design and implement a methodology to monitor impacts of actions proposed in the D-EIS on CRS fish and wildlife. The monitoring methodology must monitor SAR performance and account for unintended consequences of heretofore untested spill levels. The levels of total dissolved gas (TDG) in the	To address this uncertainty and minimize risk, the Preferred Alternative includes an adaptive management plan (Appendix R). This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Preferred Alternative exceed those recommended by the EPA; both Washington and Oregon had to revise previous TDG limits imposed on river operations to allow the proposed levels of TDG that will occur with implementation of the Preferred Alternative. Monitoring of impacts will only have value if the results of monitoring are shared broadly and transparently and those results can be responded to positively.	
6659	5	John Francisco	Northwest Requirements Utilities (NRU)	The D-EIS includes a proposed adaptive management plan to respond to scenarios where actual in-river results differ negatively from estimates generated by the model(s). Federal agencies operating the CRS must be given the flexibility to execute the adaptive management plan, specifically including the authority to reduce spill levels across the CRS to levels where the aforementioned monitoring demonstrates reduction or elimination of negative consequences to salmon, steelhead and other river organisms.	The co-lead agencies anticipate using existing Regional Forum adaptive management workgroups, such as the Technical Management Team (TMT), which have proven effective in managing through unforeseen situations when they occur during the spill season. If TMT cannot resolve a real-time issue, the issue can be elevated to the Regional Implementation Oversight Group, which has representatives from sovereign entities with fisheries management responsibilities.
6659	6	John Francisco	Northwest Requirements Utilities (NRU)	The impacts, both positive and negative, of extreme spill are yet to be proven outside the CSS model and the model results should be viewed with a measure of caution. The CSS model relies on a theory referred to as latent or delayed mortality as the basis for its projected higher survival rates. To elaborate, the theory posits that although juvenile salmon have a very high survival rate, approximately 96-97% on average, past each of the lower Columbia River dams and lower Snake River dams (LSRD), that the act of going through fish bypass passage structures and powerhouses takes a toll that results in fewer returning adult salmonids. This theory, if true, would suggest that the effects of the dams on salmon are not fully captured by the measured survival rates, and that more spill may be needed to avoid passage through turbines and potentially harmful fish bypass structures.	Delayed mortality effects due to multiple potential mechanisms (transportation, multiple dam passage, route of dam passage, water quality) were considered and factor prominently in the analysis and selection of the Preferred Alternative. Further, the model results presented in Section 3.5 and Chapter 7 address levels of delayed mortality. Delayed mortality is captured directly in the CSS model for Smolt-to-Adult returns (SAR) and abundances, and is overlaid with several assumed values (10%, 25% and 50% reductions in latent mortality) in the NMFS Life Cycle model results. Potential delayed mortality in the ocean due to CRS dam passage is discussed throughout the Draft EIS.
6659	7	John Francisco	Northwest Requirements Utilities (NRU)	It is noteworthy that the higher sustained spill operations pursuant to the implementation of the Flexible Spill Agreement in 2019 represented uncharted territory. While there have been periods throughout history with high levels of uncontrolled TDG, 2019 was the first time in the operation of the FCRPS, where TDGs were maintained at levels as high as 120% on a planned and sustained basis for the entire spring spill period. While the full effects of this high and sustained spill level on juvenile salmon will not be realized for years, the earliest signs point to poor results for both juvenile salmon and returning adults. As an example, according to a NOAA Fisheries Science Center memo from September 19, 2019, on juvenile survival for the 2019 migration season, [t]he combined yearling Chinook salmon survival estimate from the Snake River trap to Bonneville Dam tailrace was 41.3% (33.8-48.9%), which was below the long-term average of 48.9%.1 The memo goes on to note that, [t]he combined Snake River Steelhead survival estimate from the Snake River trap to Bonneville Dam tailrace was 41.2% (26.1-56.3%), which was below the long-term average of 45.7%2 We also note that in 2019, adult salmon were stalled repeatedly in their efforts to make it upstream past Little Goose Dam due to increased spill levels. Correspondingly, Claire McGrath at NOAA presented the attached report to the U.S. Army Corps of Engineers Technical Management Team (TMT) Meeting on July 10, 2019. According to the TMT meeting minutes, Ms. McGrath concluded, 1 Preliminary survival estimates for the passage of spring-migrating juvenile salmonids through Snake and Columbia River dams and reservoirs, 2019 2 Preliminary survival estimates for the passage of spring-migrating juvenile salmonids through Snake and Columbia River dams and reservoirs, 2019 - 5 - that despite varying results from the data tools, all of the indicators did consistently point to lower than expected conversion rates and slower travel times in the Lower Monumental to Little Goose reach. The 2019 YTD (as of 7/10) conversion of PIT-tagged adult Chinook from Lower Monumental to Little Goose was 96.2%, whereas the historical average for EOY conversion is 98.3%.3 Many would argue that one year of implementation does not represent a statistical sample, but we point to these initial findings as clearly demonstrating the uncertainty related to extreme spill operations and proof of the need for effective monitoring of impacts and clear action plans to respond if necessary.	The benefit of flexible spill operations to salmon and steelhead relies largely on reduction in PITPH, which is projected to result in increased Smolt-to-Adult return rates (SARs). Therefore in-river survival doesnt tell the whole story. The commenter is correct in that one year of in-river data to assess the benefits of flex spill is not adequate. It will likely take years to understand the true effect because adult returns are required to calculate SARs. The Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts to juvenile migrants.
6659	8	John Francisco	Northwest Requirements Utilities (NRU)	ey Power Supply Observations The D-EIS correctly notes that the four LSRD produce an average of 1,100 megawatts of carbon free electricity each year. That is enough to power a city the size of Seattle. More importantly, due to their location, the LSRD generate power that is more easily distributed to the smaller and more rural NRU member utilities that rely on that power to sustain small towns and irrigate crops for food and export outside the region. Regional power planners are sounding the alarm that the Pacific Northwest is headed for an electricity shortage. The Northwest Power & Conservation Council4 , the Northwest Power Pool5 , consultancy E3 6 , and Energy Strategies for the Western Interstate Energy Board7 , have all issued significant warnings about a potential energy shortage or even blackouts resulting from the retirement of thousands of megawatts of the regions coal plants. Notably, all these forecasts assume that the LSRD remain in place. As disturbing as this risk is with the LSRD in place, the CRSO D-EIS indicates that removing the LSRD from the resource mix would double the risk of blackouts in the region.	The comments about the importance of the four lower Snake River dams for regional power reliability and carbon emissions are consistent with the EIS findings. The EIS analyzed two resource portfolios to replace the hydropower generation of the four lower Snake River dams, both of which maintain regional power system reliability. See Section 3.7.3.5, pages 3-904-910 in the Draft EIS. Under these replacement portfolios, regional power rate pressure increases. See Section 3.7.3.5, at 3-918-924; and Table 3-166 in the Draft EIS. Without replacement resources, however, the statement about the effects of breaching the four lower Snake River dams on regional resource adequacy and power reliability is consistent with the findings of the EIS. See Section 3.7.3.5, Effects on Power System Reliability, at page 3-903; and Appendix H, Table 2-1 in the Draft EIS. The EIS also finds, consistent with the comment, that increasing retirement of coal power plants in the region would adversely affect regional power reliability. See Appendix H, Section 2.3, Sensitivity of LOLP to Assumptions about Coal Capacity in the Draft EIS.
6659	9	John Francisco	Northwest Requirements Utilities (NRU)	Breaching of the LSRD would run counter to current and emerging state policies to curb or eliminate greenhouse gas emissions in the electricity sector. Since the relatively recent start of the CRSO EIS process in 2016, Washington State enacted the Clean 3 7/10/2019 Columbia River Technical Management Team Draft Facilitators Summary 4 NWPCC - Pacific Northwest Power Supply Adequacy Assessment for 2024 5 NWPP - Exploring a Resource Adequacy Program for the Pacific Northwest 6 E3 Projects Substantial Capacity Shortfall in the Pacific Northwest 7 Energy Strategies & Western Interstate Energy Board- Western Flexibility Assessment 8 Columbia River System Operations Draft Environmental Impact Statement Executive Summary, 25-27 - 6 - Energy Transformation Act requiring utilities in Washington to transmit electricity that is coal free by 2025 and carbon neutral by 2030. Earlier this year, Oregons Governor Brown issued an executive order9 to curb greenhouse gases. These actions are certainly only the beginning of stricter emission regulations on the electricity industry. The D-EIS demonstrates that replacing the clean renewable hydropower generated by the LSRD with a lowest cost resource portfolio, consisting primarily of natural gas generation, would increase carbon output in the electricity sector by 10%, in direct conflict with state regulatory policies. 10 Replacing the carbon free generation from the LSRD with non-carbon emitting resources would cost $1 billion and could result in 25% retail rate increases. Utilities who get all of their wholesale power from BPA would see the full brunt of this increase. A rate increase of that size simply isnt tolerable. In many cases, consumers will be unable to pay the additional costs without forsaking other basic needs. The LSRD play another critical role in the clean energy paradigm of the Northwest. To meet the carbon reduction and overall climate change goals, the region will need to add thousands of megawatts of wind and solar power. Wind and solar power generate power intermittently. The LSRD already fill the crucial role of balancing and stabilizing the grid and this need will increase as more intermittent generation is added to the grid. The CRSO D-EIS notes that the LSRD provide roughly 1,100 average megawatts of carbon-free electricity each year under average water conditions, but they can provide over 2,000 megawatts of sustained peaking capabilities during the winter.10 The D-EIS also indicates, the Bonneville Power Administration will often carry up to 25% of its hourly reserves on the LSRD, in part to balance renewables on the grid.10 This flexibility makes the LSRD vital as we move to a cleaner grid.	The comment makes various statements about the importance of hydropower and the four lower Snake River dams for the regional power system and achieving clean energy goals; these statements are consistent with discussions and findings in the EIS. Specifically, the importance of hydropower generation from the dams for resource adequacy and power system reliability is consistent with the findings of the EIS, as is the statement that replacing lost hydropower generation with renewables under Multiple Objective (MO) Alternative 3 (which includes breaching of the four lower Snake River dams) could cost up to $1 billion. The EIS further describes the operational characteristics of the four lower Snake River dams in Section 3.7.3.5, Lower Snake River Full Replacement (Used in Rate Sensitivity Analysis).
6659	10	John Francisco	Northwest Requirements Utilities (NRU)	Other Socioeconomic Considerations Although NRU is organizationally focused on the power sector, we recognize the cumulative impacts of changes to the CRS on the customers served by our member electric utilities. Breaching the LSRD would eliminate barging of goods from rural communities to the confluence of the Snake River with the Columbia River. The loss of barging as a transportation mechanism for agricultural goods would significantly increase truck traffic, especially during the condensed harvest. Tractor trailers would be added to narrow rural roads significantly increasing safety risks, adding additional 9 https://www.oregon.gov/gov/Documents/executive_orders/eo_20-04.pdf 10 Columbia River System Operations Draft Environmental Impact Statement Executive Summary, 25-27 - 7 - costs to already shrinking margins on agricultural crops and increasing carbon emissions. The loss of irrigated land associated with breaching of the LSRD would be devastating to the rural communities served by NRUs members. Irrigation is not only beneficial for increasing yields and allowing flexibility in crop choice, irrigation often allows the farming of otherwise infertile land. Without access to the pools formed behind the LSRD, many multi-generational farms would cease to exist. With the demise of those farms comes the loss of support jobs that sustain the most vulnerable communities.	Environmental and human health impacts associated with increased emissions to shipping goods by rail and/or truck are evaluated and described in the Air Quality Section (3.8), and increase health and safety concerns due to increased truck traffic on roadways and potential for increased accidents are described in the Navigation and Transportation Section for other social effects (Section 3.10.3.5). This EIS discusses engineering solutions (pipeline extensions for example) in Chapter 3.12 Section 3.12.3 Environmental Consequences - Specifically under Region C under the MO3 alternative (see page 3-1267, line 3244, in the Draft EIS) and in Appendix N. The report which this EIS draws upon, as discussed, concluded that modifying the existing pump system was cost prohibitive. In Region C under the MO3 alternative this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres. This is discussed in Section 3.12.3 under Region C and the MO3 alternative.
6662	1	felice.kelly@gmail.com	N/A	The proposed flexible spill plan is not sufficient to save salmon populations, especially because flex spill will not significantly reduce the transit time of juvenile fish, as shown from the implementation of a similar Flex Spill plan in 2019. One of the issues with flex spill is that it provides the Corps with the flexibility to spill when hydro needs are low, which is usually during the day, while salmon migrations are often highest at night, when spill is lower, reducing its beneficial effects	The CSS model predicts that Smolt-to-Adult return (SAR) rates will increase for both Snake River spring Chinook and steelhead with median values well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, which includes the flexible spill operation measure. While the Draft EIS analysis did consider and present juvenile fish travel time through the CRS, the benefit of flexible spill to salmon and steelhead relies largely on reduction in the proportion of fish passing through powerhouses, which is projected to result in increased SARs. Therefore in-river survival and travel time does not tell the whole story. It will likely take years to understand the true effect because adult returns are needed to calculate SARs. The Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts on juvenile migrants.
6662	2	felice.kelly@gmail.com	N/A	In addition this plan fails our orca populations. Southern Resident Orcas depend on abundant salmon for their survival, and best available science says that breaching the lower four snake river dams gives Southern Resident Orca the best chance for recovery. The DEIS says that breaching the dams would have a negligible effect for orca, but the orca scientists have repeatedly advocated for the breaching of the lower four Snake River dams to restore the salmon populations that the orca depend on.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.
6662	3	felice.kelly@gmail.com	N/A	Finally, the Draft EIS fails to honor our treaty promises. Native tribes are more than simply river stakeholders as they have inherent rights as first people. Native nations also have treaties with the United States government which gives them sovereign status. Indigenous people gave up thousands of acres of their land for the right to hunt and fish in their usual and accustomed places, a promise which has not been kept by the government.	The 19 Federally recognized Tribes in the Columbia River Basin have been consulted and provided input on the Draft EIS. The co-lead agencies recognize these Tribal governments as sovereign nations and appreciate and respect their perspectives. Tribal interests are summarized in Section 3.17. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic.
6666	1	Aaron Lieberman	Idaho Outfitters & Guides Association	Background The Snake Basin and its tributaries in Idaho have a disproportionate importance to the Columbia Basin and to downstream users, where 19% of total Columbia River Basin flow originates. Historically, the Snake River has produced 55% of the total Columbia Basin summer steelhead, 45% of the total Columbia Basin summer chinook, and 39% of the total Columbia Basin spring chinook. Once producing over 1.5 million wild chinook in the 1880s, Snake River stocks have shown precipitous declines by as much as 99%. Numbers have run as low as 1,167 wild chinook in 1995. Because of these declines, wild-origin Snake River Basin sockeye, spring/summer (sp/ su) chinook, fall chinook, and steelhead have all been listed under the Endangered Species Act (ESA). 3 Our hatchery stocks have also shown declines in the uppermost reaches of the Columbia and Snake River System, threatening Idahos recreation and tourism industry. Idaho releases more than 18 million hatchery sp/su chinook for recreational angling opportunity, but lately our state has struggled to even reach broodstock needs across multiple sub-basins. Idaho fishing seasons are greatly suppressed, have reduced take limits, or been outright shut down as a direct impact of low fish returns.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. For MO1, MO2, MO4, and the Preferred Alternative (PA), the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the PA and MO4 (i.e., models show either beneficial or adverse effects on anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term. In addition to the stressors caused by the maintenance and operation of the CRS dams, there are many other stressors to these fish populations from outside the CRS hydro-system. These include, poor ocean conditions, harvest, access to habitat, among others. Current ocean conditions have limited adult returns up and down the west coast regardless of migration impediments.
6666	2	Aaron Lieberman	Idaho Outfitters & Guides Association	II. THE DEIS FAILS TO EVALUATE ECONOMIC IMPACTS OF THE NORTHWEST SALMON AND STEELHEAD FISHING INDUSTRY 4 The dEIS entirely fails to consider the economic impacts of the Northwests salmon and steelhead fishing industry. When evaluating the economic impacts of each alternative, the analysis completely ignores the sportfishing economy and its estimated contribution of over $757 million in Idaho alone (over $2 billion region-wide) . 1 Just as Snake River salmon and steelhead play a disproportionate role in the historical Columbia River abundance, salmon and steelhead fishing also plays a disproportionate role in small Central Idaho economies. Idaho riverside towns are overwhelmingly rural and heavily dependent on natural resource and recreational based economies. In Idaho, fishing for salmon and steelhead is estimated at 20-25% of total angling effort. There is an estimated $757 million in total spending for fishing in Idaho yearly in which salmon and steelhead fishing correlates to between $151.4-189.25 million per year to the state. Idaho salmon and steelhead anglers spend almost twice as much as cold water anglers, and three times as much as warm water anglers . 2 American Sportfishing Industry. https://asafishing.org/industry/american-sportfishing-1 association-highlights-barriers-to-economic-success-in-idaho-salmon-discussion/ O Laughlin, Jay. 2005. Economic Impact of Salmon and Steelhead Fishing in Idaho: Review of 2 the Idaho Rivers United Report. College of Natural Resources, University of Idaho. Issue Brief No. 6. https://www.webpages.uidaho.edu/fish510/PDF/Steelhead%20economics.pdf 5 Table 1: Summary of Regional and Other Social Effects .	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial, although quantitative impacts from fish modeling results are limited. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the range in estimated visitation in the long-term in the lower Snake River, including recreational fishing, and that it would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The social welfare effects under MO3 on commercial fisheries (Section 3.15.3.5) are described as major and beneficial in the long-term in this reach, with increases in regional economic effects if commercial fish catch rates increase. The reports the commenter cites have been reviewed and incorporated into the analysis (see Region C Sections 3.11.2.2, 3.11.3.2, and 3.11.3.5).
6666	3	Aaron Lieberman	Idaho Outfitters & Guides Association	3 The agencies analysis of regional and other social effects in shown in Table 1 above. The dEIS relied solely on qualitative, rather than quantitative analyses to evaluate impacts despite the existence of several current studies on the economic contributions of outdoor recreation and Slide presented by Army Corps of Engineers to Idaho Governors Salmon Working Group 3 March 2020. 6 sportfishing in states with anadromous fish runs. This contrasts with the analysis of water supply, irrigation, navigation, and hydropower generation, all of which were evaluated quantitatively. At the March 5, 2020 Idaho Governors Salmon Workgroup meeting, an Army Corps of Engineers economist stated economic impacts of sportfishing were outside the scope of the EIS, despite all other resources evaluated in the analysis with quantified effects.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial, although quantitative impacts from fish modeling results are limited. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the range in estimated visitation in the long-term in the lower Snake River, including recreational fishing, and that it would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The social welfare effects under MO3 on commercial fisheries (Section 3.15.3.5) are described as major and beneficial in the long-term in this reach, with increases in regional economic effects if commercial fish catch rates increase. The reports the commenter cites have been reviewed and incorporated into the analysis (see Region C Sections 3.11.2.2, 3.11.3.2, and 3.11.3.5).
6666	4	Aaron Lieberman	Idaho Outfitters & Guides Association	In 2001, Idaho anglers enjoyed a single year spike in the Chinook salmon runs returning to the Snake, Clearwater, and Salmon Rivers. Anglers totaled 448,000 days fishing salmon during the 2-4-month salmon seasons, generating $46 million to 15 river communities and $43 million to the rest of the state . That year, the spring Chinook season brought $10 million to Riggins alone 4 (estimated population 417), where the total spending that year was $44 million . That same year 5 Lewiston saw $8.8 million and Orofino $8 million from the same salmon season. Just as robust salmon and steelhead returns can provide an economic boom to these riverside towns, feeble returns can devastate them. During the four-month steelhead fishing closure on the Clearwater River in 2019, the Clearwater Region missed out on $8.6 million a month ($34.4 U.S. Fish and Wildlife Service and U.S. Bureau of the Census (2003). 2001 National Survey of 4 Fishing, Hunting, and Wildlife-Associated Recreation. Idaho. FHW/01-ID Rev. U.S. Dept. of the Interior and U.S. Dept. of Commerce. 20. http://www.census.gov/prod/2003pubs/01fhw/fhw01id.pdf Idaho Fish and Wildlife Foundation. 2003.https://idfg.idaho.gov/press/salmon-fishing-valuable-5 idahos-economy. 7 million total), with the majority of the loss in Clearwater County . The Idaho Fish and Game 6 Commission then re-opened the fishing season in 2020 for only catch and release opportunity for hatchery-origin steelhead. These losses can and will be felt for years following the 2019 steelhead fishing season closure for businesses directly and indirectly tied to steelhead	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial, although quantitative impacts from fish modeling results are limited. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. Again, there is uncertainty around recreational and commercial fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. However, the EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative,

				fishing. A survey in 2001 concluded that if salmon fishing were not available in Idaho, 73% of Idaho salmon fishermen would travel and spend their money elsewhere . 7	supporting jobs, income, and tourism businesses. The social welfare effects under MO3 on commercial fisheries (Section 3.15.3.5) are described as major and beneficial in the long-term in this reach, with increases in regional economic effects if commercial fish catch rates increase.
6666	5	Aaron Lieberman	Idaho Outfitters & Guides Association	Structural and operational measures to the Columbia River System identified in the dEIS will have profound impacts on Snake River anadromous fish and the corresponding riverside towns reliant on adult fish returns. It is unacceptable that the dEIS, despite thousands of pages of other analyses, did not include publicly available data sources to quantify both the economic potential of abundant fish returns as well as the devastating financial impacts of declining salmon and steelhead populations on rural communities in Idaho and throughout the Pacific Northwest. III. THE PREFERRED ALTERNATIVES STRUCTURAL AND OPERATIONAL MEASURES FALL SHORT TO RECOVER SNAKE RIVER BASIN SALMON AND STEELHEAD Data sourced from Kathryn Tacke, Idaho Department of Labor. https://billingsgazette.com/6 outdoors/steelhead-fishing-closure-hammers-idaho-economy/article_481f7f8c-7a85-5a7ebf5c-029b53b9144f.html Idaho Fish and Wildlife Foundation. The Economic Impact of the 2001 Salmon Season in 7 Idaho. 2003. https://www.webpages.uidaho.edu/fish510/PDF/FishingEconReport.05.pdf 8	There are benefits and costs associated with operating the lower Snake River projects. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. In addition, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. Again, there is uncertainty around recreational and commercial fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. However, the EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
6666	6	Aaron Lieberman	Idaho Outfitters & Guides Association	The preferred alternative in the dEIS does not adequately provide for salmon and steelhead population recovery because it will not improve smolt to adult rates (SARs) to levels identified and accepted by scientists as necessary for harvest or recovery. The Northwest Power and Conservation Council has identified SAR ranges from 2-6% as necessary for true recovery for anadromous stocks. This range provides a gauge of whether life cycle survival rates can both 8 avoid extinction and make progress toward broad-scale salmon restoration. Harvestable populations require consistent SARs of around 4% to meet the National Marine Fisheries Services 48-year recovery standard for sp/su chinook in the Snake River basin. Current SARs for Snake River sp/su chinook sit just under 1%, which is less than half of the minimum SAR range the Northwest Power and Conservation Council has affirmed for multiple years as necessary for maintenance of existing populations. This is a far reach from the mid-to upper goals of 4-6% SAR identified as population abundance and recovery . 9 It is important to consider survival in all life stages and in certain areas of the Columbia River system when assessing SARs. Snake River sp/su chinook and steelhead consistently display some of the lowest SARs in the Columbia River Basin, despite enduring the same pinniped predation, ocean conditions, and downstream fishing pressure. Studies have displayed that survival rates of sp/su chinook is lower than similar downriver populations that experience fewer Independent Scientific Advisory Board. Review of the 2014 Columbia River Basin Fish and 8 Wildlife Program. 2018. https://www.nwcouncil.org/sites/default/files/isab-2018-3review2014fwp23march.pdf CSS 2016 Annual Report, Chapter 7, Petrosky et al. http://www.fpc.org/documents/CSS.html9 9 dams . Despite the dEIS claiming that juvenile survival is high through the lower Snake River, 10 the 2019 CSS report estimates only 48% juvenile survival from Lower Granite dam to Bonneville Dam for Snake River steelhead from 1994-2019. Snake River chinook survival is estimated only slightly better at 54% on average. The CSS Report noted that the risk of mortality increases by about 12% for each powerhouse encounter a juvenile salmon experiences . This 11 CSS report does not even account for mortality in reservoirs. Additionally, there is evidence that Snake River chinook suffer substantial delayed mortality as a result of their outmigration experience in the smolt stage . 12 Schaller, H.A., and C.E. Petrosky. 2007. Assessing hydrosystem influence on delayed 10 mortality of Snake River stream-type Chinook salmon. North American Journal of Fisheries Management 27:810-824. CSS Annual Report. 2019. http://www.fpc.org/documents/CSS/2019CSSAnnualReport.pdf11 Williams, J.G., S.G. Smith, R.W. Zabel, W.D. Muir, M.D. Scheuerell, B.P. Sandford, D.M. 12 Marsh, R.A. Prepared by ESSA Technologies, Ltd., Vancouver, B.C. for the Fish Passage Center (Portland OR) and U.S. Fish and Wildlife Service (Vancouver WA). 147 pp. http://www.fpc.org/ Schaller, H.A., C.E. Petrosky and E.S. Tinus. 2014. Evaluating river management during seaward migration to recover Columbia River stream-type Chinook salmon considering the variation in marine conditions. Canadian Journal of Fisheries and Aquatic Sciences. 71:259-271. 10 Table 2: Comparison of Alternatives of In-River Surival, PITPH, and SARs for Snake River Spring Chinook, relative to the No Action Alternative . 13 Table 3: Comparison of Alternatives of In-River Survival, PITPH, and SARs for Snake River Steelhead, relative to the No Action Alternative . 14 Refer to footnote 2.13 Refer to footnote 2.14 11	It should be noted that the 2-6% Smolt-to-Adult return (SAR) target referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the Preferred Alternative analysis, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The co-lead agencies conclude the expected outcomes for salmon and steelhead associated with MO3 are appropriately acknowledged and framed appropriately with impacts to other authorized purposes.
6666	7	Aaron Lieberman	Idaho Outfitters & Guides Association	Management actions taken in the PA predict SARs for Snake River sp/su chinook to reach 2.7% at best, as shown in Table 2. Table 3 shows the estimated SAR under the PA is even lower for Snake River Steelhead at 2.4%. At worst, the Life Cycle Model predicts an extinction trajectory under the PA with a SAR below 1%, with Snake River sp/su chinook SARs predicted at a troubling 0.81%. The Fish Passage Center conducted the analyses of the alternatives through the Comparative Survival Study (CSS). The analyses concluded that the PA results in a SAR less than one percent 36-39% of the time for yearling chinook and steelhead, while MO3 results in a SAR less than 12 one percent only 12-19% of the time. The MO3 yields SARs greater than two percent up to 68% of the time compared to the PA of 37% of the time . 15	The co-lead agencies disagree with this comment and instead stand by the data and results presented in the draft CRSO EIS. Estimates of Smolt-to-Adult returns (SARs) (and all other fish metrics) represent the average outcome of 80 different river flow conditions, not the best outcome as portrayed in this comment. As these values represent an average, there will be many river conditions that produce SARs above the 2.7% average and many that produce values below that estimate. As noted by the ISAB in their review of the CSS model results generated for this EIS (ISAB 2020-1), changing climate conditions should be carefully assessed when considering potential impacts to salmon and steelhead, but the co-lead agencies note the concerns raised by the ISAB regarding the CSS's quartile range analysis and the likelihood or probabilities of SARs falling below 1 percent or above 2 percent. The co-lead agencies will evaluate that analysis as it evolves but are not relying on the probability analysis at this time. As noted in the response above, there is a wide range in predicted outcomes between CSS and NMFS modeling approaches. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be reduced under the Preferred Alternative, and on average, SARs are expected to be above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The expected outcomes for salmon and steelhead associated with MO3 are appropriately acknowledged and framed appropriately with impacts to other authorized purposes.
6666	8	Aaron Lieberman	Idaho Outfitters & Guides Association	Table 4: Escapement goals for wild-and natural-origin Snake River salmon and steelhead aggregated at the species level. Ten-year average returns to Lower Granite Dam calculated for years 2008-2017. NOAA minimum abundance threshold represents values that NOAA has identified to minimize long-term extinction risk. Escapement goals to the Snake River basin include populations in Washington, Oregon, and Idaho. Proposed escapement goals to Idaho include the component of the Snake River basin aggregate that returns to spawn in Idaho tributaries . 16 Table 4 above further highlights the inadequacy of the PA SAR projections to minimize the long term extinction risk for wild-and natural-origin Snake River salmon and steelhead. Idaho will From the Chapter 2 CSS analyses and March 3, 2020 presentation of the CSS analyses to the 15 Pacific Fishery Management Council Habitat Committee on the CRSO-EIS Idaho Department of Fish and Game (IDFG).2019. Fisheries Management Plan 2019-2024. 16 Idaho Department of Fish and Game, Boise, USA. 13 simply never dig out of the 10-year return averages and trend towards recovery goals with SARs >4% for sp/su chinook, steelhead, and sockeye with the PA projections.	See response to Comment 6666-6.
6666	9	Aaron Lieberman	Idaho Outfitters & Guides Association	Despite clear evidence for the management actions and structural changes needed to recover Snake River anadromous stocks, the dEIS focuses on the No Action Alternative (NAA) as the basis for therange of alternatives. The NAA has been rejected by courts and is the sole reason that this dEIS analysis has been conducted. We believe the agencies should not champion the PA SAR improvements off of a legally flawed baseline. The agencies should step away from claiming the PA operations will meet the objectives and needs just because it provides minor improvements to the flawed NAA and towards actions that will keep fish alive through the system and analysis out of the courts. The final draft should incorporate a complete alternative that benefits multiple users, but our organizations will not support implementation of river system operations that may continue to contribute to the extinction of salmon and steelhead. It is a disservice to all Idaho communities reliant on salmon and steelhead to settle with an alternative that simply holds the line	NEPA requires evaluation of effects of alternative potential actions against a baseline approach of status quo, the "no action alternative." The data analysis and evaluation should help determine which actions would be most effective. The legal status of the No Action Alternative is not relevant to analysis of potential action effectiveness.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				just above the threat of extinction and does not strive for abundance. Strong salmon and steelhead runs are part of the Northwests historical identity and is the very reason why the Salmon River is named. We cannot continue to accept the action agencies inadequate analysis only to move the goalposts of success and provide for minimal improvements to our fish populations while Idahos riverside communities continue to dwindle as a direct result of these actions.	
6666	10	Aaron Lieberman	Idaho Outfitters & Guides Association	IV. THE DEIS DOES NOT ADDRESS CLIMATE CHANGE AND ASSOCIATED IMPACTS FROM WARMER CONDITIONS THROUGHOUT THE FCRPS. While the dEIS studies a wide range of alternatives, it does not address in detail the impacts of climate change on salmonids in the long term. Millions of dollars have been spent to improve spawning and rearing habitat for salmon and steelhead- much of that in central Idaho- in part to combat climate change. This has led to small improvements in fish populations and natal stream survival rates and will continue to be an important action in the future. However, continuing to pursue habitat improvements as the primary way to recover Snake River stocks will fail because it hinges upon fish first making it to these spawning and rearing areas. The improvements from habitat restoration and natal stream temperatures may not be enough to offset the conditions that salmonids must endure when entering the FCRPS during their out-migration as well as during their return as adults through multiple reservoirs, which exposes fish to heightened stressors, including temperature. This is especially true when accounting for climate change in the near and long term future.	Historically, water temperatures in the lower Snake River were warm (USGS 1960, 1961, 1964; Corps 2002a). Observed historic water temperatures show that average monthly water temperatures during July and August, in the 1950s, averaged 7 to 8 degrees Fahrenheit higher than today's conditions, while maximum daily differences were 10 to 12 degrees Fahrenheit higher. The differences observed in the lower Snake River today, as compared to historical conditions, are a result of the middle and upper Snake River reservoirs combined with the influence that Dworshak Dam operations. The EIS analysis shows that when breaching the four lower Snake River dams, nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. The models showed minor changes in the Columbia River under MO3, indicating that the operations of the CRS dams have a limited ability to reduce temperatures in the lower Columbia River. Summer water temperatures exiting the Snake River are typically 1 to 3 degrees Fahrenheit warmer than the receiving Columbia River temperatures. Even though the cold water released from Dworshak during the summer is less than 50 degree Fahrenheit, the volume of water released is less than one tenth of the flow in the Columbia River. Since the distance between the confluence of the Snake and Columbia Rivers is about 180 miles downstream from Dworshak, the impact on water temperatures is negligible. Regionally high air and water temperatures result in water quality standard exceedances that are beyond the ability of the CRS to cool. Overall the conclusion in the Draft EIS is that MO3 would be beneficial to anadromous fish for a number of reasons, but other objectives must also be considered in the selection of a Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change and, unfortunately, they have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. Therefore it was not possible to reliably model water temperature changes under climate change for incorporation to either of the fish models. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature and anadromous fish. These analyses are documented in Section 4.2.3 for the multiple objective alternatives and Section 7.8.4 for the Preferred Alternative. Overall, the Preferred Alternative is expected to result in benefits to anadromous salmon and steelhead. The analysis in Section 7.8.4 recognizes that some of the benefits to fish from the Preferred Alternative could be offset by the effects of climate change.
6666	11	Aaron Lieberman	Idaho Outfitters & Guides Association	The dEIS should put more emphasis on evaluating the impacts of climate change on Snake River salmonids. The dEIS only evaluates these impacts on a 25-year scale while economics were evaluated on a 50-year timeframe. Because of the discrepancy in time scales, the PA implements almost no mitigation to offset the negative impacts climate change will have over the next 50 years or more. The 25-year analysis downplays the potential compounding effects of the reservoir and slack water system on salmonids and yields a PA that does little to combat this 15 threat. After the appropriate analysis and time scale is implemented in the analysis, the action agencies should incorporate new measures to mitigate for the impacts of climate change. In the meantime, the agencies should consider spilling at 125% TDG over all Columbia and Snake River dams during out-migration to reduce the water transport time and should adjust operations that will drastically reduce reservoir temperatures in late summer and early fall for adult returns.	The temporal scope of the EIS is assumed to be 25 years from the signing of the Record of Decision (ROD) in order to have a similar period of analysis for comparison of effects across resources for all multiple objective alternatives. While the Preferred Alternative was developed largely focused on the analysis based on historical and synthetic hydrology, climate change data was also considered. Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives, including the Preferred Alternative. With the uncertainty associated with climate change, it is important that we establish methods for adapting and increasing flexibility on the system. There are measures in the Preferred Alternative that are adaptive to emerging changes in climate and ensure there is flexibility to respond to future changes. One example of this is the habitat restoration program that counters increased stream temperature with deeper pools and more shaded areas. With respect to fish results under the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. Finally, the Preferred Alternative includes the Juvenile Fish Passage Spill Operations measure, which includes spill up to 125% total dissolved gas at certain projects given existing operating constraints
6666	12	Aaron Lieberman	Idaho Outfitters & Guides Association	V. THE DEIS ANALYSIS OF IMPACTS OF MO3 IS INCOMPLETE It is well documented that Columbia Basin salmon smolt are targeted by avian predators and warm water fish species that thrive in the warm slack water from numerous reservoirs throughout the system. However, the methods used in the dEIS do not accurately predict how predation rates vary across the range of alternatives and, in particular, MO3. In MO3, the COMPASS model actually predicts an increase in predation rates on wild fish because of the elimination of hatchery fish. MO3 assumes that all hatchery fish production in the Snake River basin would cease to exist because BPA would not be obligated to mitigate for the impacts of the Snake River dams. However, both of these assumptions are incorrect. Predatory fish are well adapted to slow moving water provided by the reservoir system and will be an increasing threat in the future as climate change continues to improve conditions for warm-water species. Higher water velocity under MO3 will greatly reduce encounter rates between salmonids and predators, decrease the suitable habitat for predator species, and decrease predator densities. The assumption that hatchery efforts will be terminated with MO3 shows that the scope of the dEIS is too narrow to solve the multiple issues the CRSO faces. Hatcheries provide robust recreational opportunities 16 and reduce fishing impacts on wild fish. It is likely that hatcheries will be needed for years, even in actions such as MO3, to help meet mitigation goals until wild stocks are fully recovered. We supports continued implementation of hatcheries to provide for recreational opportunity in Idaho while wild stocks continue to recover.	The Draft EIS acknowledges that with the breaching of the four lower Snake River dams in MO3, there would no longer be an obligation to fund the Lower Snake River Compensation Plan, which accounts for much of the hatchery production in the basin and other mitigation activities could be adjusted. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. The fish models are based upon data collected from past fish runs and there is no data available to inform a quantitative analysis for wild fish in the absence of hatchery fish. Over time, increased returns of wild fish would be expected as wild fish replace hatchery fish, and the Snake River resident fishery would improve as the reservoir habitats transition to riverine. The long term overall effect of MO3 would be beneficial for Snake River salmon and steelhead as well as resident fish, so no mitigation for this effect was identified. Additional hatchery production would be in place for limited years to offset the short term dam breaching and construction effects. Mitigation measures were proposed for both anadromous and resident fish for a transitional period for the breaching of the four lower Snake River dam embankments, as described in Sections 5.4.3.2 and 5.4.3.3. Proposed mitigation includes two years of hatchery production along with trap and haul operations for the anadromous fish during this period. These mitigation measures would reduce adverse effects to resident and anadromous fish in Region C. Although there is uncertainty, the quantitative and qualitative analysis use current high quality information and best available science to predict the effects. With respect to the Preferred Alternative, the fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals.
6666	13	Aaron Lieberman	Idaho Outfitters & Guides Association	The evaluation on the loss of irrigated acres in MO3 is incomplete. The dEIS states that all irrigated acresreceiving water from the current pumps would no longer be irrigated (with condition) and would convert to dryland pasture (without condition). This may be true if the action agencies proceeded with only breaching the four Snake River dams with no mitigation plan in place, but it is far from a realistic action that would be taken. The dEIS does not provide any opportunities to evaluate actions that can be taken that are outside administrative authority, so the public is left with an unrealistcally dark picture of what MO3 may bring to farmers and irrigators who currently rely on a dammed Snake River system. This analysis also perpetuates the notion that it is either fish or farms in the Northwest, which could not be further from the truth. MO3 should have included an evaluation, even if out of the administrative scope, that showed the possibility of legislation to provide federal funds to modify irrigation systems, upgrade rail infrastructure, and mitigate for the loss of barging along the Snake River to allow the continuation of an extremely important economic and social sector of the Northwest.	This EIS discusses engineering solutions (pipeline extensions for example) in Section 3.12.3 Environmental Consequences - Specifically under Region C under the MO3 alternative (see line page 3-1267 line 3244 in the Draft EIS) and in Appendix N. The report which this EIS draws upon, as discussed, concluded that modifying the existing pump system was cost prohibitive. In Region C, under the MO3 alternative this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres. This is discussed in Section 3.12.3 under Region C and the MO3 alternative. As described in Chapter 5 Mitigation, specific regulations guide the development of appropriate mitigation measures to address environmental impacts. If MO3 were to be selected as the Preferred Alternative, more detailed evaluations and NEPA would be needed along with congressional authorization and appropriations to assess the engineering requirements of the project and to potentially further refine and develop mitigation measures. However, it should be noted that as described in Section 5.1.1., Overview of Mitigation, mitigation measures developed as part of a NEPA process are not intended to indicate the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures described. But rather, it provides a list of potential mitigation needs, some of which could be implemented by other agencies, officials and/or the public who would potentially benefit from the mitigation measures.
6666	14	Aaron Lieberman	Idaho Outfitters & Guides Association	VI. THE ACTION AGENGIES PARTICIPATION AND RESPONSE DURING THE DEIS OPEN COMMENT PERIOD WAS INADEQUATE Covid-19 17 The Northwest is feeling the very real threat of the COVID-19 outbreak, and many towns near the Columbia and Snake Rivers are rightfully focused on community health at this time. A comment extension was requested by dozens of organizations, federal legislators, city officials, and chambers of commerce to allow time for impacted individuals to focus on health and safety first before engaging on the dEIS. We believe this comment extension was warranted and is common practice, but the action agencies denied any opportunity to provide for in-person meetings and comment opportunities in the future by adhering to the original timeline. We believe this is yet another missed opportunity in the EIS process where Idahoans have been excluded from adequate participation and a federal process has been pushed forward on an arbitrary timeline during unprecedented times for our nation. Failing to provide adequate public participation in this process will certainly lead to further public distrust and will likely perpetuate the cycle of litigation surrounding the FCRPS.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The meeting format made the public meetings equally accessible for the public, regardless of their location. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
6666	15	Aaron Lieberman	Idaho Outfitters & Guides Association	BPA response during comment period On March 30, Bonneville Power Administrations Senior Spokesperson delivered responses to various reporters to clarify issues identified by constituents during the ongoing public comment period. We believe this response was first, an inappropriate action during an open comment period and, second, did not provide legitimate rebuttals. BPAs email focuses on the Snake River Dams operations and the Administrations financial situation- two of the most debated subjects tied to this process. From this response, it is obvious that BPA does not seek robust discussions on impactful changes to the Columbia River system and only has the agencys self-interest in 18 mind. We believe BPAs response is a narrow, incomplete analysis of all factors and will only limit broad input from Americans in the future, undermining the NEPA process.	Bonneville provided clarifying information based on information included in the draft CRSO EIS to correct inaccurate media reports. The clarifying information focused on how Bonneville collects revenue, the power characteristics of the four lower Snake river dams, and the impacts of breaching on Bonneville's customers.
6666	16	Aaron Lieberman	Idaho Outfitters & Guides Association	VII. CONCLUSION For decades, the action agencies have been boasting minor tweaks to the Columbia River system. The agencies peddle that salmon and steelhead will recover under a new analysis that proposes more minor tweaks, while the agencies own data shows otherwise. Courts have consistently struck down the action agencies analysis, with recovery of salmon and steelhead at the crux of the issue. In National Wildlife Federation, et al. v. National Marine Fisheries Service, et al., 184 F. Supp. 3d 861 (D. Or. 2016), Judge Simon concluded the previous analysis focus on essentially the same approach to saving the listed species-minimizing hydro mitigation efforts and maximizing habitat restoration. Despite billions of dollars spent on the efforts, the listed species continue to be in a perilous state. He rejected the analysis and demanded a new study, stating One of the benefits of the NEPA analysis, which requires that all reasonable alternatives be analyzed, is that it allows innovative solutions to be considered and may finally be able	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives, including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				to break through any bureaucratic logjam that maintains the status quo...The FCRPS remains a system that cries out for a new approach. A NEPA process may elucidate an approach that will finally move the listed species out of peril. 19 It is not only the judicial branch that sees the water seeping through the cracks in the Columbia River System management framework and the consistent failure of system operations to save Snake River salmon and steelhead. The Northwest Power and Conservation Council states that despite $16.3 billion spent on fish and wildlife restoration, all Snake River anadromous fish remain at high risk of extinction . The Governors of Idaho and Washington have convened 17 working groups comprised of dozens of stakeholders in an attempt to break through the administrative logjam to seek solutions that are collaborative and encourage outside thinking that may save anadromous fish and the communities that rely on them. The PA, if implemented, will continue to fall short of benefiting Idaho riverside communities, anadromous fish, ratepayers and taxpayers. Our organizations fully recognize that this complex balance is too large for any administrative levers pulled alone to solve. A true solution to keep all parties whole and to save our anadromous fish from the risk of extinction will require congressional action from our Northwest leaders. Legislation is needed to address strategies and actions that will substantially recover anadromous fish populations while providing certainty in the future for ratepayers and others who currently rely on the status quo. This dEIS provides negligible benefits while risking another round of litigation in the courts and several more years of depressed wild salmon and steelhead returns. With the PA, the action agencies have proven yet again they are willing to continue to spend time, resources, and money to run out the clock on Information presented by Russ Thurow, U.S. Forest Service, to Idaho Governors Salmon 17 Workgroup meeting January 17, 2020. 20 our anadromous fish, riverside communities, sportfishing industry, and our way of life in the Northwest.	The co-lead agencies recognize that there are many effects to salmon and steelhead populations outside those associated with the operation, maintenance and configuration of the dams, including ocean conditions. A whole ecosystem approach would be welcomed by the co-lead agencies, who will be active participants in regional discussions and solutions for achieving broader recovery objectives.
6666	17	Aaron Lieberman	Idaho Outfitters & Guides Association	THE DEIS DISREGARDS THE ECONOMIC CONTRIBUTIONS AND IMPACT OF SALMON AND STEELHEAD FISHING, AND GUIDING, IN IDAHO AND THE NORTHWEST. 1 Our goal has been to develop an approach to river management that balances these multiple perspectives and can serve as a springboard to continued progress in the region on recovery and mitigation for fish and wildlife, reliable and affordable clean electricity, and economic vitality for the many communities that depend on the CRS for their livelihoods.2 Whereas the CRSO DEIS process acknowledges The Opinion and Order from US District Court for the District of Oregon, which states the EIS should evaluate how to ensure that the prospective management of the CRS is not likely to jeopardize the continued existence of any endangered or threatened species, the CRSO process, within the framework of the National Environmental Policy Act, also ostensibly identifies broad-based environmental and socio-economic impacts associated with the proposed alternatives. However, in its analysis of the [socio]economic impacts of the respective Multiple Objective Alternatives, the CRSO DEIS fails entirely to consider the Sportfishing economyits contributions and the anticipated impacts of the respective alternatives to it. Despite the dEISs utter and complete ommitance, the importance of these fish and the outfitting & guiding industry to these rural Idaho communities cannot be overstated. Ours is an industry that has long been negatively impacted by the decline in sportfishing opportunities for salmon and steelhead, in our businesses as well as their respective communities economically, culturally and socially. According to the Idaho Outfitters and Guides Licensing Board (IOGLB), there are currently between 1500 and 2000 guides in Idaho Licensed for, and reliant on, Salmon and Steelhead fishing. Approximately 80% of these resident Idaho Outfitters live in and contribute to the economies of communities with an average population of ~500. Idaho riverside towns, where these Salmon and Steelhead outfitters and guides reside and operate, are overwhelmingly rural and heavily dependent on natural resource and recreational based economies. According to the Idaho Department of Labor, the annual average earnings of steelhead guides is ~$23,000. Using the Income Multiplier generated for our industry by the Idaho Department of Labor, that represents and economic contribution of between $58,650,000 and $78,200,000 associated with Salmon and Steelhead guides alone. This figure, staggering in and of itself, does not include the broader impact and generated spending of the outfitters3 that employ those guides, not least the induced spending of those businesses and professionals nor that of their clients in their respective communities and Idaho as a whole. 4 The importance of salmon and steelhead fishing in rural Idaho communities and their economies is thrown into still sharper relief when framed in terms of the States Sportfishing economy on the whole (beyond outfitting and guiding specifically). On the whole, the sportfishing economy contributes an estimated $757 million dollars per year in Idaho alone.5 Based on estimates from the Idaho Department of Fish and Game regarding the proportionate angling effort for Salmon and Steelhead, that would extrapolate to a base contribution of between $151-189 million/year to the State for Salmon and Steelhead fishing. Table 1: Summary of Regional and Other Social Effects. The agencies analysis of regional and other social effects is shown in Table 1 above. Whereas the Action Agencies plan details the impacts on other industries/sectors, including agriculture, subsidized barging, and power generation, the dEIS relies solely on qualitative, rather than quantitative analyses to evaluate impacts of/on sportfishing (not to mention Idahos outfitters, guides, and rural fishing communities)despite the existence of several current studies on the economic contributions of outdoor recreation and sportfishing in states with anadromous fish runs.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
6666	18	Aaron Lieberman	Idaho Outfitters & Guides Association	This contrasts with the analysis of water supply, irrigation, navigation, and hydropower generation, all of which were evaluated quantitatively. For all management alternatives and their Preferred Alternative, the economies of recreation and fishing (from guiding, outfitting, hotels, restaurants, gas stations, boat shops, license fees, etc.) were not even accounted for despite existing, publicly available data. At the March 5, 2020, Idaho Governors Salmon Recovery Workgroup meeting, an Army Corps of Engineers economist stated economic impacts of sportfishing were outside the scope of the EIS, despite all other resources evaluated in the analysis included quantified effects. In 2001, during the height of our modern day anadromous fish returns to Idaho, anglers fished 475,000 days for steelhead and 448,000 for salmon.6 The 2-4-month salmon seasons generated $46 million to 15 river communities and $43 million to the rest of the state.7 That year, the spring Chinook season brought $10 million to Riggins alone (estimated population 417), where the total spending that year was $44 million. That same year Lewiston saw $8.8 million and Orofino $8 million from the same salmon season. In 2003, the Idaho Department of Fish and Game calculated that sportfishing generated $438 million in direct spending, including $32 million on outfitters and guides. (Adjusted for inflation, that would amount to $598,197,213 statewide and $51,898,388 on outfitters and guides, again, without factoring in additional, standard multipliers.)8 Just as robust salmon and steelhead returns can provide an economic boom to these riverside towns, feeble returns can devastate them. During the four-month steelhead fishing closure on the Clearwater River in 2019, the Clearwater Region missed out on $8.6 million a month ($34.4 million total), with the majority of the loss in Clearwater County.9 The Idaho Fish and Game Commission then re-opened the fishing season in 2020 for only catch and release opportunity for hatcheryorigin steelhead. These losses can and will be felt for years following the 2019 steelhead fishing season closure for businesses directly and indirectly tied to steelhead fishing. A survey in 2001 concluded that if salmon fishing were not available in Idaho that 73% of Idaho salmon fishermen would go elsewhere.10 Fishing outfitters, guides, and their rural communities continue to helplessly watch the downward arc of Idahos anadromous fish. Their hardship is not hypothetical; it is real and immediate and longendured. That the dEIS neither quantified the economic potential of abundant fish returns nor the devastating financial impacts of declining salmon and steelhead populations on rural communities in Idaho and throughout the Pacific Northwest is unacceptable. The economic and cultural impacts of salmon and steelhead in Idaho must be given full consideration by the federal agencies that control this system. Previous EISs included such information, but this newest iteration does not.	There are benefits and costs associated with operating the lower Snake River projects. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. However, the EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of Sections throughout the document. The Fisheries Section 3.15 as well as Section 3.17, in particular, include discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries Section 3.15.2.1, which includes Sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries. The studies that the commenter notes were reviewed and a number of these studies were included in the analysis (see Sections 3.11.2.2., 3.11.3.2, and 3.11.3.5).
6666	19	Aaron Lieberman	Idaho Outfitters & Guides Association	THE DEIS IS INADEQUATE TO RESTORE SALMON & STEELHEAD The dEIS Executive Summary acknowledges its impetus as being in response to the need to review and update management of the CRS, including evaluating impacts to resources in the context of new information and changed conditions in the Columbia River basin, and further, that the operation and maintenance of the Columbia River System affects threatened and endangered fish populations within the region, and the co-lead agencies are committed to mitigating these effects. Despite the Congressionally authorized and mandated objectives of the Columbia River Systems Operations, not least the calls from stakeholders across the region for actions that will lead to recovery of listed and endangered Snake River stocks of Salmon and Steelhead, the Preferred Alternative identified in this dEIS fails to put forward operational and structural measures/changes to improve smolt to adult rates (SARs) to levels identified and accepted by scientists as necessary for harvest or recovery. This failure has largely to do with the fact that the dEIS uses the legally discounted No Action Alternative (NAA) as its baseline for relative improvements vis-a-vis Smolt-to-Adult Return (SAR) metrics. To put it very simply, the approach is not dissimilar from a student receiving a failing grade of 50% on a test, then claiming to have rectified the shortfall by an improvement to 55% the next time around. Rather, the dEIS selects strategies already in use and makes small tweaks to reservoir releases in the higher tributaries. Both central approaches in the PA are already in use, and while each has utility in particular cases and in degrees, neither have yielded results approximating Federal obligations to conserve endangered fish	See response to Comment 6666-6. In addition, the agencies used current, high quality modeling information consistent with NEPA and did not rely on information contained in the Plan for Analyzing and Testing Hypotheses (PATH) Weight of Evidence Report (ESSA Technologies 1998), which is over 20 years old and does not reflect current CRS operations.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				populationeven just above extinction-trend levels. The Northwest Power and Conservation Council (NPCC) has identified SAR ranges from 2-6% as necessary for true recovery for anadromous stocks (this range provides a gauge of whether life cycle survival rates can both avoid extinction and make progress toward broad-scale salmon restoration). The NPCC 2%6% SAR objectives are consistent with analyses conducted by PATH, in support of the 2000 Biological Opinion of the Federal Columbia River Power System (FCRPS) found that median SARs of 4% were necessary to meet the National Marine Fisheries Service (NMFS) interim 48-year recovery standard for Snake River spring/summer Chinook; meeting the interim 100-year survival standard required a median SAR of at least 2%.	
6666	20	Aaron Lieberman	Idaho Outfitters & Guides Association	Current SARs for Snake River sp/su chinook sit just under 1%, which is less than half of the minimum SAR range the Northwest Power and Conservation Council has affirmed for multiple years as necessary for maintenance of existing populations. The Comparative Survival Study (CSS) also notes in its 2017 annual report that 1% SAR is associated with population decline. This is a far reach from the mid-to-upper goals of 4-6% SAR identified as population abundance and recovery. 11 It is important to consider survival in all life stages and in certain areas of the Columbia River system when assessing SARs. Snake River sp/su chinook and steelhead consistently display some of the lowest SARs in the Columbia River Basin, despite enduring the same pinniped predation, ocean conditions, and downstream fishing pressure. Studies have displayed that survival rates of sp/su chinook is lower than similar downriver populations that experience fewer dams.12 Despite the dEIS claiming that juvenile survival is high through the lower Snake River, the 2019 CSS report estimates 48% juvenile survival from Lower Granite dam to Bonneville Dam for Snake River steelhead from 1994-2019. Snake River chinook survival is estimated only slightly better at 54% on average. The CSS Report noted that the risk of mortality increase by about 12% of each powerhouse encounter a juvenile salmon experiences.13 This CSS report does not even account for mortality in reservoirs. Additionally, there is evidence that Snake River chinook suffer substantial delayed mortality as a result of their outmigration experience in the smolt stage.14	See response to Comment 6666-6.
6666	21	Aaron Lieberman	Idaho Outfitters & Guides Association	Management actions taken in the Preferred Alternative estimate high-end SARs for Snake River sp/ su chinook to reach 2.7%. The anticipated SAR for Snake River Steelhead under the Preferred Alternative is worse still at 2.4%. The Life Cycle Model predicts a potential extinction trajectory under the PA with a SAR below 1%, with Snake River sp/su chinook SARs predicted at a troubling 0.81%. Beginning in 2013 the Comparative Survival Study (CSS) workgroup began developing life cycle models for the purpose of examining survival at specific life stages, which is a critical component of NOAAs Biological Opinion on the operation of the Federal Columbia River Hydrosystem. This modeling provides integrated assessments of tributary smolt production, main-stem passage survival, ocean survival, and smolt to adult return rates. At the request of the Federal Action Agencies, the CSS used the Grande Ronde Life Cycle Model and the cohort-specific model to analyze six federal operational alternatives for the Columbia River Systems Operations (CRSO) Environmental Impact Statement (EIS), using the 80-year water record. The Fish Passage Center conducted the analyses of the alternatives in this dEIS through the Comparative Survival Study (CSS). The analyses concluded that the Preferred Alternative results in a SAR that is less than one percent 36-39% of the time for yearling chinook and steelhead, while MO3 results in a SAR less than one percent only 12-19% of the time. The MO3 yields SARs greater than two percent up to 68% of the time compared to the PA of 37% of the time.	The co-lead agencies used current high quality data and the best available science in the analysis in the CRSO EIS. Specific to salmon and steelhead, the agencies used both two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return (SAR) rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. SAR values reflect the methods used for estimation, and this should be taken into account when comparing estimates against the Council's regional SAR objectives for recovery. The Council did not prescribe a specific method of SAR calculation. SARs reported by hatcheries using coded wire tags often incorporate a harvest correction factor for ocean, recreational and Tribal harvest. Due to the different approaches of the models, including the length of the historical survival time series, use of different hatchery and natural origin populations, and other factors, the two models estimated substantially different SAR under the No Action Alternative for Snake River spring Chinook: 0.88% from the NMFS COMPASS model, assuming no latent mortality, and 2.0% SAR from the CSS life cycle model, which is within the Council's targeted range for recovery.
6671	1	N/A	N/A	In an increasingly electronified and digitized world, we are seeing unprecedented amounts of stress placed upon the power grid. At the same time, demand for green energy has also skyrocketed due to political and environmental concerns. Though more and more avenues are becoming available for production of said green energy, many options have the same problem: They do not adequately meet the schedule of the grid. The ideal solution for this problem would be battery storage. Unfortunately, battery storage is still an area of science that could benefit from further refinement and economy of scale. Until then, the availability of resources that are non-carbon producing, renewable, and responsive to changes in the grid as well as relatively low cost such as hydroelectric power, is invaluable. Not only does hydro power spool up quickly when demand needs to be met, but it can also in some situations double as storage for excess power produced by the grid in times of low demand. It is much easier to control when the gates of a dam open than when the sun shines or the wind blows. Since the primary electro-physical issue faced by the power grid today is the increasingly bipolar shape of demand, the ability to shift to high production in a short amount of time is a great advantage. With this in mind, it is particularly disturbing to see the possibility of breaching or reducing the efficacy of the Lower Snake River Dams (LSRDs) in Multiple Objective Alternatives 3 and 4. The Draft EIS wisely rejects these alternatives, both of which would have extremely negative impacts on the hydropower system. To accept the loss of 1,000 1,300 average megawatts of hydropower production, especially in this time of national emergency and faltering economy, would seem the height of negligence when confronted with the issues of the electrical industry today.	The statements regarding the importance of hydropower as a reliable power source, and the ability of hydropower to integrate renewables and adjust generation to meet load are consistent with the findings of the EIS. Consistent with the comment, the EIS did identify battery storage as a potential solution for replacement sources. See Section 3.7.3.5 - Potential Replacement Resources and Associated Costs. Regarding the concern voiced by the comment regarding the loss of power under Multiple Objective alternative 3 and Multiple Objective alternative 4, the co-lead agencies developed a Preferred Alternative that provides an adequate, efficient, economical and reliable power supply and includes a combination of measures from all the alternatives with consideration of environmental, economic, and social effects.
6674	1	boleneus@gmail.com	N/A	My comment is attached. I included three images in the attached document. I would like to send a more readable version of images 1 and 3 if allowed. Combines the two images are approximately 3.5 MB in a single document which I have been unable to reduce size. Please use my email to request that I forward the larger document by other means.	The co-lead agencies are sorry for any technical difficulty experienced. It is accurate that the website had file size limitations that were listed for a single entry. That was not to limit you in your comments, but to alert you to submit in multiple entries either contact the CRSO info helpline, or mail your materials to the P.O. Box listed on the CRSO website and on other news and informational releases.
6674	2	boleneus@gmail.com	N/A	Theme: The region will not be supplied with adequate electric supply if the four dams on the Snake River are removed. The removal of dams will exacerbate supply problems worsened by Washingtons new electricity law. If the four dams on the Snake River are removed the supply of electricity will be at deficit conditions, permanently. IMAGE 1 [letter contains graph] shows the electric supply and load from Bonneville Power Administration during two weeks in November. All forms of electricity are included: Hydro, Fossil, Biomass, Wind and Nuclear. There is excess supply of electricity. Note the blue area, which includes all sources of supply exceeds the load. This is the current situation. The supply is adequate. It is comfortable. This data is provided by BPA. BPA transmits electricity to 120 utility customers with enough electricity to supply seven to nine (7-9) Seattles. The purpose in this comment is to shown how well the state is supplied with electricity today but that electricity after 2045 will not supply all customers full time. Three figures (images) are produced to compare today with the same two weeks in 2045 under conditions that will exist for two weeks in 2045 in addition to show how poorly is the performance of wind electric generation. IMAGE 1. SHOWS SUPPLY OF ELECTRICITY FROM THE BONNEVILLE POWER ADMINISTRATION SYSTEM DURING TWO WEEKS IN NOVEMBER 2019 COMPOSED OF WIND (RED), FOSSIL/BIOMASS (GREEN), NUCLEAR (ORANGE) AND HYDRO (BLUE). LOAD (or demand) IS THE BLACK LINE. TOTAL PERIOD SHOWN EACH WEEK IS 168 HOURS, A TOTAL OF 336 HOURS (only 226 hours of 336 are shown). NOTE, IN PARTICULAR THE WIND GENERATION (RED) IS NOT PRODUCING MUCH ELECTRICITY. WIND EXCEEDS 50% OF ITS CAPACITY FOR ONLY 16 HOURS (4.8%) DURING THE 336 HOURS SHOWN. The problem that will exist in the future when the new electricity law takes full effect, the Clean Electricity Transformation Act of 2019 in Washington, if the dams are removed involves a combination of problems that will develop and events to reduce supply that are not foreseen: 1. The new electricity law in Washington passed into law in 2019 requires that all fossil fuel sources are removed by 2025, requires that renewable forms of electricity provide supply for what is lost from fossil fuels. It also requires that Washingtons electricity can produce no carbon dioxide by 2040 or ZeroCarbon. The Zero Carbon adds to the developing dilemma.	The statement that Multiple Objective Alternative 3 (which includes breaching the four lower Snake River dams) would have substantial effects on the regional power system, requiring replacement resources to maintain reliability, is consistent with the findings of the EIS. See draft EIS, Section 3.7.3.5, Effects on Power System Reliability at page 3-903 and Appendix H, Table 2-1. The EIS did not analyze all potential effects of the Washington's Clean Energy Transformation Act legislation; however, it does acknowledge potential effects on regional reliability due to upcoming coal power plant retirements and finds that additional marginal renewable power resources would be needed, consistent with the concern voiced by the comment. Appendix H, Section 2.3, Sensitivity of LOLP to Assumptions about Coal Capacity, provides additional details. The statement also makes suggestions about concerns regarding the reliability of wind power; the EIS did not find wind cost-effective at improving power system reliability, and thus, did not include it in the base case resource portfolios. The graphic cited by the commenter appears to rely on data provided by Bonneville's transmission business line: https://transmission.bpa.gov/Business/operations/Wind/baltwg3.aspx. This graphic displays Bonneville's load and resource balance within its Balancing Authority Area, which includes non-Federal generation and load, and omits Federal generation and Federal load not located in the Bonneville Balancing Authority Area (BAA, the area for which Bonneville's transmission business line is responsible). The footnote to the table notes that this is the load in the BAA. It does not include all of the load served by the Federal Columbia River Power System(FCRPS) for which Bonneville's power business line is responsible. Bonneville sends power to customers that are in other BAAs. Conversely, some of the load within Bonneville's BAA is served by other power providers. Thus, this graphic does not assess whether power from the FCRPS is surplus.
6674	3	boleneus@gmail.com	N/A	2. Between 2025 and 2040 cap and trade will begin to take effect because Washington is not allowed to use carbon-emitting sources of electricity although through cap and trade with the electricity imported from other places but customers will be charged very large fees for the extra service that could amount to an extra 20 cents to 30 cents per kwhr. The carbon is not reduced as the electricity still emits carbon, but it is emitted somewhere else.	The EIS considers Washington's Clean Energy Transformation Act and examines the potential costs of carbon compliance including the Washington state fees for fossil-fuel generation mentioned in the comment (see Section 3.7.3.1, Additional Power Rate Sensitivity Analysis and Other Regional Cost Pressure Analysis, Cost of Carbon Compliance in the draft EIS).
6674	4	boleneus@gmail.com	N/A	3. By 2030 natural gas must be removed from the generation of electricity and must end completely by 2045. This ends all fossil fuel generation before 2045. Cap and trade will expand but cap and trade does not end the emission of carbon. Renewables will continue to expand at a high cost. The cost of electricity from wind generation in Ontario was estimate to cost 40 cents to 44 cents per kwhr. 4. The cost of electricity will continue to increase as renewable forms of energy expand while the actual supply will increase only slightly. A 100 % increase in renewables can only increase supply by 10%. The cost of renewables increases but the supply does not increase a similar amount. Renewables cannot replace fossil fuels but few understand this dilemma. Wind generation now in Washington amounts to 4,782 megawatts (MWs) that comes from about 3,000 wind turbines. Image 2 is a chart from BPA to show the number of days per month that the approximate 3,000 wind turbines produce no electricity over a period of 776 days from Jan. 1 2013 to Feb. 10 2015 when all turbines were producing. This is full demonstration of the wind deficit. The turbines are there but they produce almost no electricity. Note the number of autumn to wintertime days during the November 2013 to March 2014 is 18+15.4+10+18.2+10.2+9.2 days, a total of 81 days. The reason that wind turbines do not produce electricity is because the wind is calm most times during these periods when the need is greatest. It would not matter how many turbines are built, the turbines cannot produce electricity when wind is calm for several days and the deficit becomes far more severe during autumn-winter times. The deficit during the 776 day period is 265.2 days without electricity. During these times when wind is not producing electricity other forms of electricity must fill the deficit. Removing Snake River dams places electric supplies at great risk. IMAGE 2. SHOWS NUMBER OF DAYS PER MONTH THAT WIND GENERATION FALLS BELOW 5% OF CAPAICTY ON THE BONNEVILLE SYSTEM, A TOTAL OF 265.2 DAYS DURING THE 776 DAY PERIOD FOR JAN. 1 2013-FEB. 10 2016.	The comment analyzes wind power generation and notes the seasonality and variability of wind energy in the region, which is consistent with information presented in the EIS. In the renewables portfolio, the EIS did consider wind power as a potential replacement resource; however, wind power was not found to be cost-effective at improving regional power reliability compared to solar resources. See Appendix H, Power and Transmission, Section 2.3, page 2-12 in the Draft EIS. The EIS acknowledges the dispatchability issues of renewables, as noted by the comment, in Section 3.7.2.2, Power System Flexibility and Reliability.
6674	5	boleneus@gmail.com	N/A	5. The number of customers will increase by 1.25% to 1.5% per year enlarging customer load, the number of customers needing electricity by 2045 will increase by 37.5% All of these factors increase dependence while decreasing supply. Fast forward to 2045 as shown in image 3. The image 3 shows supplies of electricity remaining during the two week period in November 2045, with hydro supply decreasing by 11.5%, the amount now capable from	The comment states multiple concerns with the adequacy of the power system to meet growing demand in the future should loads increase and reliance on fossil fuels decline. While the specific calculations and analysis presented in the comment are not consistent with the findings of the EIS, the broader concerns about reliability of the future power system are consistent with discussions in the EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the 4 Snake River dams and fossil supplies eliminated. The image shows load increasing by 37.5% to accommodate additional customers. It shows an additional 4,000 MWs of wind turbine capacity added to overcome the loss from the four dams. Wind capacity is now 4,000 MW + 4,792 MW = 8,782 MWs total. Also 82MW of solar/biomass are also added but solar only produces electricity during daylight hours. The result shown in the image is that the supply of electricity is at a deficit condition. The deficit, the amount of electricity demand that is failed to be supplied to households is 154,820 MWs. The demand line lies above the total amount of supply illustrated. This means that for any two week period in November that 259,765 residences cannot be supplied with electricity. This amount of electricity shortage equals the load for 5 to 6 counties in the State of Washington is another way of saying that customers in 5 to 6 Washington counties are denied electric supply. IMAGE 3. SHOWS THE TOTAL ELECTRICITY SUPPLY FOR THE BONNEVILLE SYSTEM FOR THE SAME TWO WEEK PERIOD USED ABOVE BUT FOR NOVEMBER 9-17, 2045 AFTER FOSSIL SOURCES ARE REMOVED and THE FOUR SNAKE RIVER DAMS ARE REMOVED. THE RENEWABLE SUPPLY IS INCREASED BY 82 MWs (SOLAR, BIOMASS) AND 4,000 WMs (WIND). AGAIN NOTE THE WIND (RED). WIND GENERATED ELECTRICITY CANNOT PROVIDE THE SUPPLY NEEDED TO REPLACE THE COMBINED LOSSES OF THE FOUR SNAKE RIVER DAMS AND THE FOSSIL SOURCES. THE WIND IS STILL MOST OF THE AUTUMN-WINTER MONTHS AND CANNOT GENERATE ELECTRICITY. IT DOES NOT MATTER HOW LARGE IS THE FLEET OF WIND TURBINES IF THE WIND IS NOT BLOWING. ANOTHER FACTOR IS THE SOLAR ONLY PRODUCES ELECTRICITY DURING WINTER ABOUT 3 HOURS PER DAY. THE RESULT IS THAT MORE THAN A QUARTER MILLION CUSTOMERS MUST GO WITHOUT AN ELECTRICITY SUPPLY. THE MAIN REASON IS THAT RENEWABLE FORMS OF ELECTRICITY CANNOT PROVIDE A FILL TIME SUPPLY. WHO ARE THE VOLUNTEERS TO GO WITHOUT ELECTRICITY? THE DEFICIT OF ELECTRICITY SUPPLY IS 154,820 MWs WHICH MEANS 259,765 HOUSEHOLDS MUST BE WITHOUT ELECTRICITY (YELLOW ARROWS AND YELLOW LINE). THE DEFICIT PRODUCED BY THIS CONDITION IS THE SAME AS SAYING: FOR THE 3,864,000 CUSTOMERS PROMISED ELECTRICITY THAT 3,670,000 CUSTOMERS MUST DO WITHOUT ELECTRICITY.	
6676	1	N/A	N/A	The document notes that breaching the dams would cost about $955 million or about $35.4 million a year over 50 years. However, it doesnt consider current operating losses, new construction costs and repairs of dams nor the taxpayer subsidies to the Port in Lewiston, barge companies and Portland Power and Electric. These last three are operating at a substantial loss and would have to be compensated. Breaching the dams would actually save the government nearly $79 million a year in dam maintenance costs and $32 million in capital costs. Comparing breaching with continuing the same failing strategy indicates that breaching operations and maintenance costs come to $477.5 million a year which is a DECREASE in expenditures of about $729,000 annually.	The cost analysis estimates the capital and O&M costs savings that would occur under MO3 (see Tables 4-1 and 5-1 in Appendix Q). The capital costs include additional construction and capital requirements that would be needed in the future to maintain the lower Snake River dams. Section 3.10 discusses the potential effects of currently operating barge companies in a dam breach scenario. If MO3, which includes the dam breach measure, were to be selected as the Preferred Alternative, further evaluation, studies, and NEPA would be needed along with congressional authorization and appropriations to assess the requirements of the project and to potentially compensate for the changes in river conditions.
6676	2	N/A	N/A	Some say that breaching the dams would adversely affect transportation of goods along the river. However, freight transport on the Lower Snake has been in decline for 20 years. Barges no longer carry paper, pulp, logs, lumber, petroleum, or agricultural products. The waterway has been abandoned in favor of truck and rail. Concurrently, costs of maintaining commercial navigation on the Lower Snake continue to rise and are subsidized by taxpayers. These transportation methods are not profitable for the ports, the barges, or for the power produced by the dams. The transportation costs are important to consider along with the livelihood of agriculture and fishing tourism. However, the costs of new construction of rail infrastructure and new energy sources are listed WITHOUT listing the operation losses of the existing power company and its outdated infrastructure, all subsidized by taxpayers. Therefore, the DEIS is lacking in critical data and analysis.	Access to barge transportation is the most cost effective means of accessing export markets for the many grain producers in the Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS described in Section 3.10.3.5. It is true however, that barge movements on the Snake/Columbia river have declined over the past 20 years, but it also appears that the decline has stabilized over the past 10 years. The EIS finds that transportation of freight that is currently barged on the Lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term.
6688	1	sarahjmadsen@me.com	N/A	The DEIS fails to honor treaty rights of the Nez Perce, Shoshone-Bannock, Umatilla, Warm Springs and Yakama tribes.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty-specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations treaties impose. In terms of honoring our treaty obligations, the co-lead agencies comply with environmental laws and regulations and all other applicable Federal statutory and regulatory requirements, included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision-making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. Treaty rights are discussed in the Executive Summary, Section 3.16, Cultural Resources, and Section 3.17, Indian Trust Assets, Tribal Perspectives, and Tribal Interests and Chapter 7, Preferred Alternative. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic.
6691	1	maggieevans1998@gmail.com	N/A	The report does not discuss the consequences of river impoundment and hatchery rearing on the reproductive success and survival rate of the river's fish populations (Marschall et al, 2011). Due to a multitude of factors, with dams being one of the most impactful, the abundance of fish has drastically decreased over the course of the century. To accommodate for the dwindling fish populations, hatcheries have attempted to mitigate the decreasing fish populations who are disappearing due to the ongoing destruction and alteration of their habitat.The mitigation process, however, is not enough to maintain or restore the decreasing fish populations or support the organisms who are highly dependent upon them as a food source. Studies have also shown that the death rate of hatchery fish is much higher than that of wild fish (Plumb et al, 2005). In addition to there being a low survival rate among hatchery fish, studies have shown that the amount of time taken by hatchery fish to migrate down river and navigate the impoundments takes approximately twice as long as the period of time taken by wild fish populations who are already facing migration delays due to decreased water velocity caused by dam reservoirs (Johnson et al, 2019). The period of time taken while migrating downstream is critically important to other organisms who are dependent upon the fish for survival, and wild fish populations who are able to migrate in a more timely manner are not large enough to continue to sustain these species. Because the dams increase the period of time needed for wild and hatchery fish to migrate downstream, the synchronicity of migration patterns between native fish and other native organisms has been thrown off, causing a decrease in the population size or even the extinction of many important species, including apex predators such as orcas and bears. The end result will be a trophic cascade that will alter the entire ecosystem system at whole.	Hatchery programs have long been a part of the approach for salmon recovery. Based on our analysis of fish resources in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery operations are proposed. Many ESUs/DPSs of ESA-listed fish include fish produced in hatcheries. Hatchery origin fish are very important to Tribal and sport harvest in within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the three co-lead agencies have legal requirement to produce hatchery fish as mitigation for components of the CRS. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act. Changes in fish travel time through the CRS was a key metric analyzed and reported from both the NOAA models as well as the CSS models. The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).
6691	2	maggieevans1998@gmail.com	N/A	Another factor that the report failed to address was the important role that free flowing rivers have on the hydrological cycle, as well as the dispersion of nutrients and sediment. It did not mention the multitude of negative impacts that the dams are having on riparian, marine, estuarine, and freshwater ecosystems that are heavily dependent upon these sources to maintain their natural functions. According to a study by Hydrology and Earth System Sciences, anthropogenic impacts have resulted in up to 100% decrease in annual natural river discharge, with the western USA being one of the most heavily affected (Doll et al, 2009). The study also found a positive correlation between decreased river discharge and decreased fish abundance within the river basins. Sediment deposition downstream, as well as in estuaries and marine environments, have been drastically reduced over the years due to dam blockage, causing extreme environmental alterations, resulting in the collapse of important ecosystems that are no longer habitable for the native species that once thrived.	The effects that dams have on natural riverine processes are discussed in Chapter 3 of the EIS, as well as in Technical Appendix D.
6692	1	nina.englander@doj.state.or.us	Oregon Department of Justice	Unreasonable schedule that drives inadequate analyses. The lead federal agencies (Army Corps of Engineering [ACOE], Bureau of Reclamation [BOR], and Bonneville Power Administration [BPA]) proceeded with an accelerated and arbitrary schedule, dictated by Executive Order, to develop the CRSO DEIS by February 28, 2020, complete the public comment period by April 13, 2020, and have a Record of Decision (ROD) by September 2020. This timeline is significantly shorter than the court-ordered NEPA schedule, which the federal agencies informed the Court was the minimum schedule that would allow them to do [the NEPA process] right." NWF v. NMFS, 3:01-cv-00640-SI, ECF No. 2070 at 5 (June 3, 2016). This abbreviated schedule simply did not provide the lead federal agencies enough time for their technical teams to conduct thorough and robust analyses required by NEPA. Taking time to do the necessary work is essential for such a complex system of 14 dams. The rush to produce the document is evident in the technical shortcomings of the CROS DEIS, as expressed below and in our attached technical comments.	NEPA requires agencies to consider the significant environmental consequences of their proposed actions and inform the public about their decision making. NEPA also requires that the agencies look at a reasonable range of alternatives that can meet the purpose and need of the action. To meet this requirement of NEPA, after evaluating scoping comments from the public, the co-lead agencies collaborated with cooperating agencies in teams of technical experts through several iterations to create 12 alternatives that could meet the CRSO EIS Purpose and Need Statement: first, eight single objective alternatives, and then four multiple objective alternative (MOs). The MOs were determined to be more efficient and reasonable, as the MOs were composed of combinations of measures from the single objective alternatives and could meet a variety of the defined objectives as well as the Purpose and Need Statement. The Draft EIS considered the environmental consequences of the range of alternatives and disclosed to the public those consequences through Chapters 3, 4, 5, 6, and 7. The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The co-lead agencies were not able to extend the timeline to prepare the EIS and they considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public hearings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate as per NEPA regulations. The CRSO website reminded the public on April 9, that they should plan to submit comments by the close of the comment period.
6692	2	nina.englander@doj.state.or.us	Oregon Department of Justice	Compressed public comment period; denied request for extension. I wrote to you on March 27, 2020, and expressed concern about the national health emergency related to the Coronavirus Disease-2019, and its associated impact on the CRSO DEIS public comment schedule. In particular, the CRSO DEIS was released for public comment on February 28, 2020. Two weeks later, on March 13, 2020, President Trump declared a national emergency concerning the outbreak of COVID19. On March 23, 2020, I issued Executive Order 20-12, which requires all Oregonians to stay home unless absolutely necessary. I have also ordered all Oregon schools closed for the remainder of this school year. President Trump declared COVID-19 Declarations of Disaster for Washington on March 22, Oregon on March 29, and Idaho on April 9. In light of these extraordinary circumstances, the ability of all Oregonians including Oregon state agenciesto review and provide thorough comments on the voluminous CRSO DEIS was severely constrained. Similar requests for extension to the public comment period were echoed in separate letters from the federal delegation and numerous Non-Governmental Organizations. Even before the COVID-19 crisis the ACOE recognized the likelihood of an extension in a court filing, stating [i]n light of the publics interest in a meaningful opportunity to comment on a draft EIS that addresses numerous complicated and potentially controversial topics, an extension of the 45 day regulatory minimum period for public comment will likely be warranted (as is often the case for complex NEPA processes). NWF v. NMFS, 3:01-	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				cv-00640-SI, ECF No. 2070 at 15 (June 3, 2016). Despite these extraordinary circumstances, on April 7, 2020, the ACOE denied all requests for extension. I am perplexed and disappointed in this decision by ACOE, especially considering the COVID-19 pandemic is the most significant public health emergency in the past 100 years.	
6692	3	nina.englander@doj.state.or.us	Oregon Department of Justice	Dismissal of Snake River dam removal option without thorough analysis. As you know, Oregon is actively engaged in a long-standing effort to recover salmon and steelhead in the Columbia Basin as a vital part of our ecological, cultural and economic heritage and prosperity. The science is clear that removing the earthen portions of the four lower Snake River dams is the most certain and robust solution to Snake River salmon and steelhead recovery. No other action has the potential to improve overall survival two- to three-fold and simultaneously address both the orca and salmon recovery dilemma. This option reduces direct and delayed mortality of wild and hatchery salmon associated with dam and reservoir passage and provides the most resilience to climate change (e.g., reduced thermal loading in the lower Snake and Columbia rivers and better access to and from the alpine headwaters most resilient to shrinking snowpacks). These likely benefits to salmon and steelhead need to be assessed along with the impacts to power generation, irrigation, flood control, and river-dependent commerce, and how these sectors can be made whole or provided reasonable offsets associated with potential removal of the Snake River dams. The Northwest Power and Conservation Council can provide the necessary assessment of long-term costs to the power section and how they may be mitigated. Additional studies will be needed to address impacts to and offsets for irrigation, flood management, and river-dependent commerce. The CRSO DEIS does not include this comprehensive and robust assessment of the removal of the Snake River dams, and hence does not meet the standards of NEPA.	The co-lead agencies understand and acknowledge that model estimates for the MO3 alternative that includes dam breaching showed the greatest predicted potential smolt-to-adult returns (SARs) for Snake River salmon and steelhead among the alternatives. The purpose of the analysis in the EIS is not limited to salmon issues. The EIS analysis provides analysis of multiple objectives and resources of the CRS including flood risk management, water supply, hydropower generation, fish and wildlife conservation (including a variety of other species than salmon and steelhead), navigation, cultural resources, recreation and other environmental and socioeconomic resources. In addition, the EIS seeks to identify a Preferred Alternative that achieves a reasonable balance of multiple river resource needs and co-lead agency mission requirements. In addition to the benefits for Snake River salmon and steelhead of dam breaching, the analysis showed major adverse impacts, particularly to navigation, irrigation, and power supply and reliability. Dam breaching would substantially increase the likelihood of a blackout. Different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the NMFS Comprehensive Passage (COMPASS) model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase - smolt-to-adult returns (SARs) for steelhead were not modeled). SAR is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. Under the Comparative Survival Study (CSS) model, juvenile in-river survival for the Snake River spring/summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. We understand and acknowledge that model estimates for the alternative that includes dam breaching showed the greatest predicted potential smolt-to-adult returns (SARs) for Snake River salmon and steelhead among the alternatives, as well as other effects to species in both the upper and lower Columbia River. Regarding Southern Resident Killer Whales (SRKW), the population dynamics of the SRKW are complicated, and there is no one factor that contributes to the overall success of this species; however, the co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW. The CRSO EIS meets or exceeds Federal standards for an EIS. The document fully complies with CEQs Regulations for Implementing the Procedural Provisions of the National Environmental Policy Act (40 CFR Parts 1500-1508). In addition, processes for evaluation were guided by the overarching procedures described in the Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies (42 USC 1962a-2). Finally, the co-lead agencies have the expertise to analyze the power impacts, costs and potential mitigation actions and coordinated, at appropriate times with the Northwest Power and Conservation Council.
6692	4	nina.englander@doj.state.or.us	Oregon Department of Justice	Additional technical shortcomings. NEPA requires utilization of high quality information and accurate scientific analysis, as well as professional integrity, including scientific integrity, of the discussions and analyses within an EIS. Oregon state agencies have identified numerous errors and deficient analyses in the draft EIS, as detailed in our comments, which the action agencies must address in the final EIS to appropriately disclose and objectively analyze potential significant environmental impacts. The CRSO DEIS fails to identify an environmentally preferred alternative; identify a preferred alternative that satisfies the purpose and need statement; utilize high quality information and accurate scientific analyses; adequately and equitably analyze water quality, climate, and socioeconomic impacts across resources; and identify and implement reasonable mitigation measures.	NEPA does not require an EIS to include the environmentally preferable alternative. As discussed in the Council on Environmental Quality's NEPA Regulations, the environmentally preferable alternative must be identified in the Record of Decision. (see 40 C.F.R. 1505.2, "The record, which may be integrated into any other record prepared by the agency, including that required by OMB Circular A95 (Revised), part I, sections 6(c) and (d), and part II, section 5(b)(4), shall: (a) State what the decision was. (b) Identify all alternatives considered by the agency in reaching its decision, specifying the alternative or alternatives which were considered to be environmentally preferable...."). Here, the co-lead agencies wanted to benefit from public comments on the draft and final EIS before identifying the environmentally preferable alternative and will use this information to select the Preferred Alternative and identify the environmentally Preferable Alternative in their Record of Decision. Thus, not identifying the environmentally preferable alternative in the draft EIS is not a supplementation trigger under NEPA. The co-lead agencies have utilized the most current, highest quality, best available references to analyze the effects of action alternatives. NEPA requires federal agencies to assess the environmental effects of their proposed actions prior to making decisions. The Draft EIS provides a comprehensive and unbiased analysis of the effects of the alternatives and Preferred Alternative, while also considering cumulative effects within the basin, inclusive of potential mitigation actions proposed for certain resources and alternatives as described in Chapter 5.
6692	5	nina.englander@doj.state.or.us	Oregon Department of Justice	The CRSO DEIS can be used to evaluate a bridge to a more sustainable future for salmon and steelhead, while concurrently maintaining economic growth, necessary flood management for the Pacific Northwest, and protecting the viability of the hydropower system that has long provided the foundation of affordable energy for the region. If the EIS is modified to comply with NEPA as described herein, subsequent implementation of the Preferred Alternative with more robust fish measures can be an acceptable interim step if matched with a commitment and funding from the lead federal agencies to timely perform all necessary studies and analyses for refinement and clarity related to adaptive management and long-term plans for the CRSO, including preparing for potential removal of the lower Snake River dams. The process must be based on established science and have enough specificity to assure a longterm solution for salmon and steelhead, while maintaining operation of the CRS in a manner that recognizes the importance of the hydropower system to meeting the states economic and climate goals. This vision of the future can only be realized with leadership from and strong collaboration with the four states (Oregon, Washington, Montana and Idaho). It must include a formal partnership with the federal lead agencies, NOAA Fisheries, and the federally recognized tribal governments. The process to formulate that vision must also provide meaningful engagement with and input from the public and others who depend on the Columbia River System, including the energy sector, agriculture, and navigation interests. It can draw upon the work of NOAAs Columbia Basin Partnership that seeks a collaborative approach to comprehensive, integrated solutions for salmon management with full consideration of energy, agriculture, transportation, recreation, and other community needs.	The co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions and solutions achieving broader recovery objectives. The Preferred Alternative for long-term system operations, maintenance and configuration of the CRS presented in the Draft EIS is based on todays conditions and environment. Its also important to note that technology is quickly changing, as is the regions dynamic environment and energy market, and the region needs to consider new information and adaptively manage resources. The co-lead agencies recognize that no matter which alternative in the CRSO Draft EIS is identified as the Preferred Alternative, the identification would likely draw criticism from some stakeholders or sovereigns. The region includes stakeholders, sovereigns, and other interested parties with diverse and varied opinions on these very important topics, and many are strong in the belief that their perspective is the best path forward. It is important to keep in mind that factors, both human-caused and natural, that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the Columbia River System requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. The co-lead agencies look forward to participating in that discussion. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.
6692	6	nina.englander@doj.state.or.us	Oregon Department of Justice	The State of Oregon, by and through its Departments of Environmental Quality, Fish and Wildlife, Energy, Water Resources and Agriculture, reviewed and analyzed the draft Environmental Impact Statement (Draft EIS) to ensure it provides a full and fair disclosure of the significant environmental impacts of the proposed Columbia Rivers System Operations (the Project). Unfortunately, Oregon finds that this draft EIS fails in several respects to meet the requirements of the National Environmental Policy Act (NEPA). It bears repeating that the purpose of this Columbia River System Operations (CRSO) court-ordered NEPA process was to force the consideration of environmental impacts in the decision-making process. * * * [T]o consider more aggressive changes to the [CRSO] to save the imperiled listed species.1 In the courts mandate it cited the benefits of the required NEPA analysis as potentially allowing the agencies, public, and public officials to evaluate system alterations even those outside of the statutory authority of the action agencies to finally be able to break through any bureaucratic logjam that maintains the status quo.2 The Draft EIS fails to meet this court-ordered mandate, and fails to meet NEPA requirements. Remedy is still possible. The errors made in this Draft EIS can be corrected and the legal deficiencies can be remedied. The public, agencies, and all decisionmakers are better served by a Final EIS that is comprehensive, accurate, objective, and transparent in its identification and disclosure of CRSO environmental impacts and a reasonable range of alternatives to that action.	NEPA requires agencies to consider the significant environmental consequences of their proposed actions and inform the public about their decision making. NEPA also requires that the agencies look at a reasonable range of alternatives that can meet the purpose and need of the action. To meet this requirement of NEPA, after evaluating scoping comments from the public, the co-lead agencies collaborated with cooperating agencies in teams of technical experts through several iterations to create 12 alternatives that could meet the CRSO EIS Purpose and Need Statement: first, eight single objective alternatives, and then four MOs. The MOs were also determined to be more efficient and reasonable, as the MOs were composed of combinations of measures from the single objective alternatives. The Draft EIS considered the environmental consequences of the range of alternatives and disclosed to the public those consequences through Chapters 3, 4, 5, 6, and 7. The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations.
6692	7	nina.englander@doj.state.or.us	Oregon Department of Justice	Final EIS Must Include a Dam Breach Alternative Without Inclusion of Other Measures that Obscure Beneficial Impacts to Listed Species The Ninth Circuit has explained: The touchstone for our inquiry is whether an EIS's selection and discussion of alternatives fosters informed decision-making and informed public participation.3 Here, the action agencies choice to combine measures (e.g., structural components and operations of the CRSO) in each alternative that have opposing effects on the environment prevent informed decision-making by masking the environmental impacts of individual measures, effectively undermining any ability of decisionmakers or the public to discern the environmental benefits or adverse impacts of particular measures. For example, each alternative is a combination of measures with differing objectives, with consequent opposing effects on the human environment. In short, the action agencies process of screening alternatives and recombination of measures into multiple objective alternatives has sacrificed the ability to discern the environmental impacts of key measures in comparative form resulting in complete masking of benefits of certain measures. This choice has eliminated the opportunity to discern each measures, and consequently, each alternatives comparative merit. In addition, the Ninth Circuit has also clarified that [t]he existence of a viable but unexamined alternative renders an environmental impact statement inadequate.4 Oregon urges the action agencies to review and consider the proffered reasonable alternative for inclusion in the Final EIS.5 The public and public officials deserve to understand the environmental consequences of all reasonable alternatives, including the adverse impacts associated with the status quo as well the potential benefits of innovative solutions that may be outside of the action agencies existing authority.6 As the Ninth Circuit has warned, [i]t is precisely this sort of uncritical[] privileging of one form of use over another that we have held violates NEPA.	See response to Comment 6692-21. The co-lead agencies complied with NEPA by using high quality information in the EIS and making this information available to the public for review and comment. The analysis in the EIS and from public comments will be used to inform the co-lead agencies' decision in the Record of Decision. Although Fish and Wildlife is one of the authorized purposes, it is not the only purpose, and the co-lead agencies must balance all resources, and sometimes focus some purposes over others. The analysis of the Multiple Objective alternatives reflect these trade-offs and have allowed the co-lead agencies to understand the effects of emphasizing some purposes over others to seek the most acceptable balance for future operations. The Multiple Objective alternatives relied on preliminary analysis of the Single Objective alternatives to inform the combination of alternatives analyzed in the final range. The measures in the final range of alternatives were combined in deliberate ways to display the trade-offs inherent in the operation of such a complex system. The EIS clearly describes the effects analysis in Chapters 3, 4, 6, and 7.
6692	8	nina.englander@doj.state.or.us	Oregon Department of Justice	Lastly, Oregon urges the action agencies to comply with NEPAs requirement to consider whether it can carry out its proposed action in a less environmentally damaging manner, and to 3 Calif. v. Block, 690 F.2d 753, 767 (9th Cir.1982); see also 'Ilio'ulaokalani Coal. v. Rumsfeld, 464 F.3d 1083, 1094 (9th Cir. 2006) (We make a pragmatic judgment whether the [Environmental Impact Statement's] form, content and preparation foster both informed decisionmaking and informed public participation.) (quoting City of CarmelByTheSea v. U.S. Dep't of Transp., 123 F.3d 1142, 115051 (9th Cir.1997) (internal quotation marks omitted)). 4 Morongo, 161 F.3d at 575 (internal quotations and citations omitted). 5 See United Neighbors United,	The co-lead agencies disagree that the EIS focuses on a strict adherence to statutory authorities as evidenced by the co-lead agencies evaluation of breaching the four lower Snake River dams - an alternative outside existing co-lead agency authority. Moreover, the Preferred Alternative is not simply a modification of existing operations. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The CSS model, predicts that median Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and would average well above 2% (the lower end of Northwest

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Inc. v. Jewell, 831 F.3d 564, 577 (D.C. Cir. 2016) (holding failure to examine an alternative that results in less take of endangered species was error because it would better inform public by sharply defining the issues and providing a clear basis for choice among options) (quoting 40 C.F.R. 1502.14). 6 NWF v. NMFS, 184 F. Supp. 3d 861, 947-48 (D. Or. 2016) (One of the benefits of a NEPA analysis, which requires that all reasonable alternatives be analyzed, is that it allows innovative solutions to be considered and may finally be able to break through any bureaucratic logjam that maintains the status quo.). 7 See Oregon Nat. Desert Assn v. BLM, 625 F.3d 1092, 1124 (9th Cir. 2010) (quoting California v. Block, 690 F.2d 753, 767 (9th Cir. 1982) 4 select an environmentally-preferred alternative.8 NEPAs purpose is undermined where, as here, the action agencies refuse to abandon strict adherence to its existing statutory authorities. This causes two issues. First, it led the action agencies to propose a preferred alternative that merely adds a few modifications to its existing operations, which result only in a slight improvement in environmental benefits. This error is compounded by failure to include analysis of single objectives, and instead, the Draft EIS analysis includes description of alternatives that include multiple objectives that once combined prevent informed decision-making. Second, the action agencies include in their purpose and need statement fulfillment of statutory authorizations, which directly results in exclusion of any alternative that may require additional authority from Congress. For example, NEPA requires analysis of even those alternatives outside of the authority of the action agencies. The record of decision must identify all alternatives considered and specify the alternatives considered environmentally preferable. While an agency may discuss a preferred alternative in light of its statutory missions (or even economic considerations), what the agencies have done here is preclude selection of a reasonable alternative by having its purpose and need statement include carrying out its existing statutory authorizations.	Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative (increasing from 2.0% to 2.7% for Chinook, a 35% relative increase). And even though the Preferred Alternative is a multiple objective alternative, this is not a detriment, as the comment suggests. Rather, it allows analysis of the EIS objectives, separately and together, to determine the beneficial and adverse effects. Finally, consistent with NEPA, the agencies developed a Purpose and Need Statement that allowed it to evaluate alternatives within and outside existing authorities. If the agencies selected MO3, which includes breaching the four lower Snake River dams, as the Preferred Alternative in its Record of Decision, the agencies would use this EIS to seek Congressional authorization and appropriations to breach these dams.
6692	9	nina.englander@doj.state.or.us	Oregon Department of Justice	Oregon urges the Final EIS to correct the purpose and need statement as well as to incorporate throughout analysis of the proffered feasible, reasonable alternative, as an environmentally preferred alternative. Significantly, if a supplemental Draft EIS is issued that corrects these errors, Oregon is not stating that the action agencies must select the environmentally-preferred alternative nor that this alternative cannot be eliminated as the preferred alternative for potentially-legally sound reasons (example, required delay in ability to implement). Oregon is requesting only adherence to NEPA to adequately and fairly disclose and discuss all reasonable alternatives to inform the public and decision-makers of their environmental consequences. Oregon rejects the Draft EISs attempt to obscure and distort the environmental effects of breaching the lower Snake River dams, or otherwise, its omission of an option with more beneficial outcomes for imperiled species. Even if that reasonable alternative is not the eventually chosen preferred alternative, the region deserves an objective, complete analysis of the actual environmental impacts of breaching one or more of the lower Snake River dams.	NEPA does not require an EIS to include the environmentally preferable alternative. As discussed in the Council on Environmental Quality's NEPA Regulations, the environmentally preferable alternative must be identified in the Record of Decision. (see 40 C.F.R. 1505.2, "The record, which may be integrated into any other record prepared by the agency, including that required by OMB Circular A95 (Revised), part I, sections 6(c) and (d), and part II, section 5(b)(4), shall: (a) State what the decision was. (b) Identify all alternatives considered by the agency in reaching its decision, specifying the alternative or alternatives which were considered to be environmentally preferable...."). Here, the co-lead agencies wanted to benefit from public comments on the draft and final EIS before identifying the environmentally preferable alternative and will use this information to select the Preferred Alternative and identify the environmentally Preferable Alternative in their Record of Decision. Thus, not identifying the environmentally preferable alternative in the draft EIS is not a supplementation trigger under NEPA. Moreover, the preliminary analysis of the Single Objective alternatives informed the combination of measures which make up the final range of alternatives for analysis in this EIS. The CRS is a complex system with competing authorities. As such, the co-lead agencies needed to develop reasonable alternatives that could be used to operate the CRS into the future. A lower Snake River dam breach alternative would not account for operations of the rest of the system of projects and EIS purposes. The co-lead agencies, with assistance from the cooperating agencies developed a reasonable range of alternatives that could or would realistically be implemented, these alternatives were developed and analyzed. The co-lead agencies disagree that an alternative that only evaluates breaching the four lower Snake River dam is a complete or implementable alternative. The Draft EIS contains a range of alternatives intended to emphasize trade-offs required to balance competing needs in a complex system. The intent of the EIS, as stated in the Purpose and Need Statement, is to provide a plan for operations and configuration of the CRS. An EIS that presented alternatives focused only on breaching the four lower Snake River dams, as you suggest, would not provide a reasonable range of alternatives as required by NEPA. Finally, the EIS clearly articulates the impacts, costs and benefits of breaching the four lower Snake River dams.
6692	10	nina.englander@doj.state.or.us	Oregon Department of Justice	Analysis in Draft EIS is Inadequate, Inaccurate (Errors and Omissions), Evidences Bias, and Lacks Scientific Rigor NEPA requires that the Action Agencies utilize high quality information and accurate scientific analysis,9 and ensure professional integrity, including scientific integrity, of the discussions and analyses within an EIS.10 Oregon state agencies have identified numerous errors and deficient analysis in the Draft EIS, as specifically set forth below, which the action agencies must address in the Final EIS to appropriately disclose and objectively analyze potential 8 See 40 C.F.R. 1505.2(b). 9 See 40 C.F.R. 1500.1(b). 10 40 C.F.R. 1502.24. 5 significant environmental impacts to comply with that mandate.11 Further, Oregon urges the action agencies to consider removing the extraneous discussions as indicated below], as well as discussion of socioeconomic effects unrelated to environmental impacts of the CRSO. An EISs purpose is to disclose environmental impacts of the proposed action and reasonable alternatives to that action. The action agencies go to great lengths to instead discuss socioeconomic impacts on the region as a result of changes in proposed operations of the hydrosystem in contrast to the short shrift given to the proposed operations impacts on the natural and physical environment and the relationship of people with that environment.12 This appears to be the reverse situation than that discussed in Metro Edison, where here, the action agencies instead of plaintiffs attempt to utilize the Draft EIS to air [its] policy objections to reasonable alternatives involving changes in CRSO structures and operations.13 But the U.S. Supreme Courts statement is equally applicable that [t]he political process, and not NEPA provides the appropriate forum in which to air policy disagreements.14 The Final EIS should eliminate this evidence of bias. Instead, the action agencies using objective, scientific rigor must allow the public and decision-makers to assess comparative merit of alternatives in light of their environmental impacts.	The EIS evaluates the performance of the CRSO EIS alternatives with respect to multiple stated objectives, for example related to improving fish passage and survival, reliable power generation, and minimizing greenhouse gas emissions. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. Consistent with NEPA analysis framework, the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. The co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as cooperating agencies, and over 30 of those invited agreed to participate. Staff from the Cooperating Agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation, maintenance and configuration of the dams in the CRS system. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The draft EIS was subjected to two internal agency reviews by the Corps of Engineers experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available. Also, see response to Comment 6692-3.
6692	11	nina.englander@doj.state.or.us	Oregon Department of Justice	Draft EIS Fails to Include Identification or Adequate Analysis of Proposed Mitigation The U.S. Supreme Court has stated that omission of a reasonably complete discussion of possible mitigation measures [] undermine[s] the action-forcing function of NEPA. Without such a discussion, neither the agency nor other interested groups and individuals can properly evaluate the severity of the adverse effects.15 The Draft EIS includes a mere listing of potential mitigation without information or discussion regarding why such measures will be effective. NEPA requires that mitigation must be developed where it is feasible to do so, including identification of [a]ll relevant, reasonable mitigation measures.16 This Draft EIS falls far short 11 See 40 C.F.R. 1502.2f). 12 See 40 C.F.R. 1508.14 (defining human environment as used in NEPA, stating: When an environmental impact statement is prepared and economic or social and natural or physical environmental effects are interrelated, then [the EIS] will discuss all of these effects on human environment.). 13 See Metropolitan Edison Co. v. People Against Nuclear Energy, 460 U.S. 766 (1983). 14 Id. 15 Robertson v. Methow Valley Citizens Council, 490 U.S. 332, 352 (1989). 16 See 40 C.F.R. 1502.14(f); 1502.16(h); see also Council on Environmental Quality, Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations, 46 Fed. Reg. 18026 (Mar. 23, 1981), Questions 19a and 19b (requiring disclosure of full spectrum of appropriate mitigation) (All relevant, reasonable mitigation measures that could improve the project are to be identified, even if they are outside of the jurisdiction of the lead agency or the cooperating agencies, and thus would not be committed as part of the RODs of these agencies. This will serve to alert agencies or officials who can implement these extra measures, and will encourage them to do so. Because the EIS is the most comprehensive environmental document, it 6 of meeting these requirements as described more specifically below, especially with respect to mitigation necessary to offset impacts to listed species. If proposed mitigation measures are unenforceable, or lack monitoring commitments or sufficient resources to assure performance, the action agencies have no reasonable basis to conclude that such measures will effectively reduce environmental impacts of the CRSO.17 As identified in the specific state agency comments that follow, the action agencies have not sufficiently identified or analyzed possible mitigation measures to support a conclusion that environmental impacts have been reduced to less-than-significant levels. Oregon agencies have identified those that should and must be included to adhere to NEPA mandate that federal agencies [i]nclude appropriate mitigation measures not already in the proposed action or alternatives.	The co-lead agencies do not concur with the commenter's assessment that the Draft EIS did not include and analyze adequate, feasible mitigation, including mitigation measures outside the jurisdiction of the co-lead agencies. Chapter 3 described the direct and indirect effects; Chapter 4 described the future climate conditions and effects, Chapter 5 captured actions to mitigate those remaining effects, after careful screening by the teams of other potential methods (workshop matrices are included in Appendix R, Part 3). It also included a brief discussion of how those measures are anticipated to offset specific effects and is summarized in the tables of Chapter 5. Chapter 6 looked cumulatively at these effects, including the addition of mitigation, and determined the cumulative effects of the action. Appendix R includes a preliminary mitigation and monitoring and adaptive management plan in order to measure whether the actions are reaching success or triggers additional actions are needed. The co-lead agencies do not concur with the commenter's assessment that the Draft EIS did not include and analyze adequate, feasible mitigation, including mitigation measures outside the jurisdiction of the co-lead agencies. Chapter 3 described the direct and indirect effects; Chapter 4 described the future climate conditions and effects, Chapter 5 discussed the ongoing mitigation actions funded by the co-lead agencies and captured additional actions to mitigate effects from Multiple Objective Alternatives 1, 2, 3 and 4, after careful screening by the teams of other potential methods (workshop matrices are included in Appendix R, Part 3). It also included a discussion of how those measures are anticipated to offset specific effects and is summarized in the tables of Chapter 5. Chapter 6 looked cumulatively at these effects, including the addition of mitigation, and determined the cumulative effects of the action. Chapter 7 included a description of the direct, indirect, cumulative and climate effects of the Preferred Alternative as well as mitigation carried forward from the No Action Alternative and additional mitigation proposed for the Preferred Alternative. Appendix R includes a mitigation and monitoring and adaptive management plan in order to measure whether the actions are reaching success or triggers additional actions are needed. As noted in Chapters 5 and 7, implementation of MO3 and Multiple Objective alternative 4 (MO4) would have potential for significant adverse effects to several resources that could not be mitigated by the co-lead agencies. In MO3, in order to offset these effects, the EIS notes the measures that should be taken by others to: protect ground and river water quality, provide recreational opportunities, extension of irrigation and water supply pipelines and wells, and transfer of a shipping industry. Other impacts, such as loss of cruise line tourism, increased greenhouse gases, and traffic, did not have feasible mitigation measures. However these effects are discussed in the environmental justice section (Section 3.18). NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities.
6692	12	nina.englander@doj.state.or.us	Oregon Department of Justice	Action Agencies Violate NEPA By Providing an Insufficient Comment Period Given the existing public health emergency that constitutes extraordinary circumstances, Oregon finds the minimum 45-day public comment period does not comport with NEPA as it does not provide for adequate disclosure.19 Given this fact in addition to the numerous errors and omission in this Draft EIS, including but not limited to the missing reasonable alternative, Oregon requests that the action agencies circulate a supplemental Draft EIS once it has addressed all cited deficiencies in order to provide for meaningful consideration by the public and decisionmakers.20 The proposed reasonable alternative is not qualitatively within the spectrum of existing alternatives,21 and absent its inclusion, the action agencies risk not only violating NEPA but to directly contravene the courts order that required this analysis in the first instance.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
6692	13	nina.englander@doj.state.or.us	Oregon Department of Justice	Oregon Water Resources Department Comments City of Arlington in Gilliam County has a Columbia River Surface Water Right The Oregon Water Resources Department (WRD) notes that with respect to water use in north central Oregon (Chapter 3.12, Region D) the Draft EIS does not indicate that the City of Arlington in Gilliam County has a Columbia River surface water right, not currently in use. It appears that the Action Agencies did not consider this water supply use in its analysis. WRD has identified this error previously. The Final EIS should explain whether this omission is because the right is still under development and more a future water use? If this is the case, the Department disagrees, but the EIS should make this clarification.	The EIS analysis considers effects to currently used water for M&I. It is unknown when this water right will be used and how much will be used, so it is not included. This sentence will be added to Section 3.12.2.1 for clarification: Water rights that have been applied for but are not currently being used are not included in this EIS because it is unknown when they will be used and how much will be used.
6692	14	nina.englander@doj.state.or.us	Oregon Department of Justice	Need for Mitigation Draft EIS should identify and discuss mitigation for all impacts The Action Agencies concluded that the Preferred Alternative is unlikely to impact water supply obligations. The Department generally agrees. However, if adjusted in a way that lowers reservoir elevations, lowering water levels may impact intakes of surface water diversions and wells; and the Draft EIS should identify and describe sufficient mitigation of those impacts. It is also important to note that this analysis did not consider impacts on water rights issued but under development (see comment above). Impacts to those rights should also be mitigated.	NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in this chapter is not intended to indicate that the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Records of Decision (ROD). Their inclusion in this chapter serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide mitigation for the effects to private infrastructure such as irrigation pumps, wells, or private docks.
6692	15	nina.englander@doj.state.or.us	Oregon Department of Justice	Oregon Department of Environmental Quality Water Temperature Analysis The Oregon Department of Environmental Quality (DEQ) acknowledges the consideration the co-lead agencies gave to evaluating MO3 stream temperature changes that shows, in comparison to the No Action Alternative (NAA), faster stream temperature response in the lower Snake River to seasonal and diurnal changes in air temperature and solar radiation following	Generally, shallower rivers are more susceptible to warming and cooling. However, the water temperature is the result of 5 heat fluxes, volume of the river and downstream transport, therefore simple explanations are not universally applicable.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				dam breaching. Although dam breaching is expected to result in warmer spring water temperature, the overall seasonal thermal regime will become more normative. However, to provide a more complete picture on MO3 impacts on stream temperature, the co-lead agencies should provide clear conclusions in the Final EIS regarding post-breach reduced travel time of water, as faster flow rate, will influence stream temperature. DEQ suggests further describing why there is a difference between the seasonal, post-breach, lower Snake River water temperature compared with that of the NAA. Adding more detail to this section will help to elucidate why spring water temperature is higher post-breach compared to the NAA, whereas the commonly held assumption is that dam breaching will result in cooler water temperatures. For example, describe how the Snake River in the NAA is a larger body of water, which is slower to warm and slower to cool, and how this contributes to warmer spring stream temperature in comparison to MO3. This is important information for the public and 8 decisionmakers. Additionally, the Draft EIS refers only to "temperature" and should, instead, expressly clarify, as applicable, water temperature or air temperature. Chapter 4, lines 806-818, is an example of where these issues should be addressed. Suspended Sediments For MO3, the Draft EIS predicts the release of an extraordinary amount of suspended sediment and turbidity due to dam breaching. The EIS should identify best management practices that could be implemented to mitigate sediment discharges to reduce the short-term impacts associated with sedimentation resulting from dam breaching. Please identify and analyze effect of existing procedures or BMPs that would minimize release of suspended sediment in the Final EIS.	Regarding water temperatures in the lower Snake River, it is well known that reservoirs create a lag in the thermal response to environmental conditions, leading to colder conditions in the spring and warmer conditions in the fall as compared to unregulated systems. Breaching the dams would reverse these effects. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO EIS numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. The co-lead agencies' analysis shows that under a dam breach scenario, water temperatures in the lower Snake River would still exceed State water quality standards during the summer and especially during hot weather events. Details regarding this analysis can be found in the Water Quality Appendix D, Section 6.2.1.2. The impact of travel time cannot be evaluated independently from other hydraulic factors like depth. Changes in hydrology and flow have been captured in CSS and NMFS COMPASS fish modeling and analysis. Direct and indirect effects of MO3, as compared to the No Action Alternative, include downriver sedimentation as described in cumulative effects Table 6-11 (Section 6.3.1.2.4). Near-term sedimentation effects following the MO3 Breach Snake Embankments measure are predicted to last up to ten years (depending on the hydrologic regime) as legacy sediment deposits within the former reservoirs are incrementally eroded and re-deposited throughout the lower Snake Reach. Near-term sedimentation effects are expected to be particularly large in the upstream end of Lake Wallula on the Columbia River. The effects of sediment deposition at left bank recreation and boat-launch sites below the Snake confluence would likely be permanent. Long-term sedimentation effects would include continued deposition in quiescent areas prone to shoaling as a result of annual sediment delivery that had previously been trapped by the lower Snake River dams, but not directly interfere with Columbia River navigation. Mitigation actions for these potential impacts to navigation are detailed in Section 5.4.3.5 and propose dredging to maintain this reach of the Federal navigation channel. Likewise, public and private port facilities both near the confluence of the lower Snake River and on the left bank of Lake Wallula would need to conduct sequential dredging in order to avoid interruptions in service and maintain access to the navigation channel. Dredging mitigation for maintaining the Federal navigation channel would be a Corps' expense, while dredging to maintain port facilities and access to the Federal navigation channel would not be a Corps' expense. Dredging operations are expected to remain similar to No Action Alternative in the remaining reach of the Columbia River navigation channel. If MO3 was selected in the ROD, further studies and NEPA analysis would need to be performed for implementation, including engineering plans, best management practices, and mitigation for breaching the embankments of the four lower Snake River dams. The formulation of the MO3 drawdown and embankment removal plan for the four lower Snake River dams mirrored that developed in the 2002 Lower Snake River Feasibility Report/EIS. This approach includes reservoir drawdowns prior to breaching combined with the stepped approach of embankment breaching (by removing the earthen Sections of Lower Granite and Little Goose dams in year 1 and Lower Monumental and Ice Harbor dams in year 2) which are specific best management practices aimed at reducing suspended sediment and turbidity in the lower Snake River under MO3. If MO3 is identified as the selected alternative in the ROD, the co-lead agencies would further study the potential impacts and refine the elements of the plan (means, methods, and timing) as well as implementation measures to insure that suspended sediment and turbidity were appropriately mitigated in accordance with applicable laws and regulations.
6692	16	nina.englander@doj.state.or.us	Oregon Department of Justice	The Oregon Department of Energy (ODOE) appreciates the tremendous amount of work and effort that went into the analysis of the potential impacts to the power sector in the development of the Draft EIS, as reflected in Section 3.7 and Appendix H, in particular. Impacts to the power sector, as the Draft EIS shows, can be quantified in terms of the cost (or avoided cost) to the power sector of achieving other specific non-power objectives. The preferred alternative results in minimal overall costs to the power sector, especially compared to MO3 and MO4 that would incur significant costs associated with a replacement of energy due to a reduction in hydropower output, a replacement of the capacity contribution necessary to maintain the reliability of the regional power system, and mitigation of potential increased greenhouse gas emissions associated with these replacement power resources. In order to prepare for a long-term solution for salmon recovery that restores the lower Snake River, further analysis is needed to determine how to minimize or mitigate resulting costs to the power sector. This mitigation should be identified, discussed, and thoroughly analyzed in the Final EIS. While ODOE appreciates the amount of analysis that went into evaluating the estimated changes in power generation associated with MO1, MO2, MO3, MO4, and the Preferred Alternative, ODOE believes that that analysis was flawed in several important respects that will be discussed in greater detail below.	As noted by the comment, the Preferred Alternative places additional rate pressure of 2.7 percent on Bonneville wholesale power rates, which is significantly below the rate pressure associated with the effects of Multiple Objective (MO) Alternative 3 or MO4 relative to the No Action Alternative. The comment is also generally correct that this amount of rate pressure is within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control. Conversely, the power rate effects of MO3 and MO4 do not fall within the range of costs Bonneville has historically been able to mitigate through cost controls. See draft EIS, Section 3.7.3.5, at pages 3-918-924, Table 3-166 and Section 3.7.3.6, Electricity Rate Pressure, at pages 3-945-950, Table 3-182. The comment also suggests that additional analysis is needed to mitigate the resulting costs to the power sector for salmon recovery that restores the lower Snake River. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The Preferred Alternative provides substantial benefits to ESA-listed salmon and steelhead, which would contribute to recovery targets, but recovery is a broader responsibility than the co-lead agencies. Specific to power, the EIS relied on the Northwest Power and Conservation Councils 7th Power Plan and Mid-Term Update as the source for resource replacement costs. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at 3-821 and Appendix H, Power and Transmission, at Section 2.2 in the draft EIS. If MO3 was selected as the Preferred Alternative, then Congress would need to authorize this recommendation and provide implementation funding. There would also need to be additional environmental compliance processes, including NEPA processes to identify how to breach the dams and replace the power generation and transmission. As part of these processes, mitigation of these costs to regional customers would likely require a concerted effort by regional utilities, state governments, policy makers, Tribal entities, and other stakeholders and interests to collaboratively work together to find alternative means of serving regional energy needs.
6692	17	nina.englander@doj.state.or.us	Oregon Department of Justice	Power System Reliability Step 2 of the methodology for power and transmission analysis considers effects on power system reliability from the alternatives evaluated.24 Maintaining a reliable power system is a cornerstone of our daily lives and the health of the regional economy. Federal hydropower resources have made incredibly significant contributions to maintaining this reliability in the Northwest for much of the last century. That said, maintaining overall power system reliability in the Northwest is complex and multijurisdictional, involving not only BPA, but several large investor-owned utilities, consumerowned utilities, and multiple state regulators. The Northwest Power and Conservation Council (NWPCC) provides the regions most comprehensive regular assessment of the adequacy of the Northwest power system to maintain reliability into the future.25 Many of the regions electric utilities rely upon the annual resource adequacy assessment developed by the NWPCC to inform their own planning for capacity resources to maintain system reliability. Particularly as the retirements of coal units accelerate, these assessments are more critical than ever, and a complete analysis of the problem requires detailed probabilistic analysis of how the regional power system is likely to perform under a range of future scenarios and conditions. In addition, an emerging effort led by the Northwest Power Pool (NWPP), which includes BPA, is developing a proposal for the establishment of a formalized regional resource adequacy program to maintain power system reliability in the Northwest.26 Significant new details around this proposal are due to be released in 2020, with the prospect of a new regional program being established within the next couple of years. ODOE raises these issues here as important context for the analysis that is provided within the Draft EIS related to regional power system reliability. The overall reliability of the regional power system should not be the focus of the analysis within the Draft EIS.27 While we acknowledge the substantial contributions that federal hydropower resources have made and will continue to make toward maintenance of overall regional power system reliability, these issues are much broader than the scope of the Draft EIS and are already being addressed in more appropriate venues. 24 Draft EIS at 3-819. 25 Northwest Power and Conservation Council, Pacific Northwest Power Supply Adequacy Assessment for 2024. October 31, 2019. Available online: https://www.nwcouncil.org/reports/pacific-northwest-power-supply-adequacy-assessment-2024 26 For more information, see Northwest Power Pool, Resource Adequacy Program. https://www.nwpp.org/about/workgroups/12 27 Harms discussed in an EIS must have a sufficiently close connection to the physical environment. See Metropolitan Edison Co. v. People Against Nuclear Energy, 460 U.S. 766 (1983). 10 Specifically, we do not believe that the Draft EIS is the appropriate vehicle to speculate about the potential for future coal plant retirements,28 although we do not dispute that significant evidence suggests that more coal capacity is likely to retire. The likelihood of those retirements occurring is not impacted by the proposed action discussed in the Draft EIS, and any challenges that those retirements present for the regional power system will need to be assessed and dealt with irrespective of CRSO operations. A more robust analysis of the impact of these potential coal retirements requires a broader set of tools and scope of analysis than what the Draft EIS provides. That said, Table 3-147 29 summarizes the impact to power system reliability (as measured by Loss of Load Probability, the metric employed by the NWPCC in its regional resource adequacy assessment) from MO2 compared to the No Action Alternative under three different coal scenarios: Base Case (4,246 MW of coal remains operational); Limited Coal Capacity (1,741 MW of coal remains operational); No Coal Capacity (0 MW of coal remains operational). As reflected in the table, the LOLP under the No Coal Capacity scenario would be a staggering 63% (compared to the regions stated standard of 5.0% LOLP). In short, this means that even under the No Action Alternative there would be insufficient power supply available to meet electric demand at least once per year in more than 6 out of every 10 years. Power system reliability impacts of this type would be severe and historically unprecedented in the Northwest. Participants in the existing regional efforts described above are acutely aware of these potential future challenges to power system reliability and are actively working to develop robust solutions to address them. Incorporating an analysis of these speculative future challenges is not appropriate in the context of the Draft or Final EIS because: (1) this process lacks the necessary tools and regional scope; and (2) this process is intended to compare environmental impacts of multiple alternatives for Columbia River System Operations against a No Action Alternative which reflects the status quo (not a speculative version of the future). Specific Recommendation: Delete section or revise text in the Final EIS to reflect that the analysis of multiple potential future coal retirement scenarios is incomplete, beyond the scope of this process, and requires a more robust regional analysis to fully evaluate potential reliability impacts. 28 See Draft EIS, Appendix H, Section 2.3 Sensitivity of LOLP to Assumptions about Coal Capacity, at p. H-2-8 to H-2-10. 29 Draft EIS at 3-887. 11	Consistent with the comment, the focus of the EIS is the operation, maintenance and configuration of the CRS projects, and one of the purposes is to provide an adequate, efficient, economical, and reliable power supply that supports the integrated Columbia River Power System. See Section 1.2 of the Draft EIS. For the power analysis, this includes an assessment of the change in reliability if the CRS projects change operations. While the focus of the analysis is on the CRS projects, the projects do not operate in isolation from the rest of the regional system; power is traded among utilities. This is also the reason why the Northwest Power and Conservation Council, the Northwest Power Pool, Bonneville (in the annual White Book), and other organizations regularly reassess regional reliability and why individual utilities rely on these regional assessments, as noted in the comment. Changes in operations at the CRS projects affect how much power Bonneville sells to, and purchases from, other utilities. Conversely, changes in generation capacity at other utilities also affect the amount of power Bonneville sells to, and purchases from, other utilities. Reliability is one of the purposes in this EIS and Bonneville-related statutes. None of those other forums referenced in the comment, have an obligation to examine the environmental impacts of operating, maintaining and configuring the CRS. The co-lead agencies, consistent with NEPA, considered the direct, indirect and cumulative effects to regional reliability. The EIS used the best available resource information about the regional resource mix in 2017 when the power analysis was initiated. As that resource mix information changed, a study was performed to assess how the change in input would affect the analysis. The changes in the regional coal-fired generators does affect the operation of the CRS projects, and thus, was appropriately included in the power generation and transmission analysis. The comment notes that the EIS should not speculate about coal-plant retirements. In performing the sensitivity analysis of the impact of coal plant retirements, Bonneville initiated this special study in 2019. With the recent passage of Washington's Clean Energy Transformation Act (CETA) legislation and Oregon's discussions on carbon legislation, it became apparent that the distribution of coal plants was evolving rapidly. Rather than speculate about further announcements that might be made regarding coal-plant retirements, Bonneville chose as a bookend to analyze a no-coal scenario through a sensitivity analysis. While decisions about coal-plant retirements are not necessarily affected by CRS operations, there is an effect from coal retirements on both the need for, and cost of replacement resources to meet regional load. Thus, to analyze the potential effects to power generation and transmission, including reliability, the co-lead agencies, consistent with NEPA, chose not to ignore new information on coal retirements, and thus, included this information in its effects analysis. To the extent that the CRS operations induce regional capacity concerns, many load-serving entities would need to plan to build replacement resources. The framework of this EIS quantifies those effects by developing an other regional cost pressure analysis. The Other Regional Cost Pressure analysis shows the incremental resource needs to the region of the limited coal retirement scenario and the no coal scenario for each Multiple Objective alternative (MO). The Other Regional Cost Pressure analysis combines the effects of the MOs with a limited coal or no coal scenario and estimates whether incremental resources would be needed (above those identified in the MO) to return regional reliability to the level of the No Action Alternative. See Section 3.7.3.1, Additional Power Rate Sensitivity Analysis and Other Regional Cost Pressure Analysis, pages 3-829-830 in the Draft EIS. This cost is represented as an additional unassigned cost (i.e., it is not reflected in the rates analysis) because the EIS does not take a position on what entity (e.g., the region, Bonneville) would be responsible for the incremental costs created by additional coal retirements. The statement that the regional Loss of Load Probability (LOLP) under a no-coal scenario is unprecedented is consistent with the findings of the EIS. Even under the limited-coal scenario, the LOLP is extremely high. As noted by the comment, Bonneville is participating in regional forums concerned with regional resource adequacy. The EIS did not focus on addressing the needs in the No Action Alternative except to the extent that it impacts the needs of the other EIS alternatives relative to the No Action Alternative. As described above, the coal sensitivity analysis was used to provide an estimate of the incremental resources needed to maintain regional reliability in light of recent information regarding coal retirements. These retirements were announced in recent years, and the EIS identifies those resources that have been slated to retire (or are no longer able to serve regional loads) during the 2020s. See Section 3.7.3.1, Rate Sensitivity Analysis, Table 3-121, at pages 3-841-842 in the Draft EIS. This analysis is included as a sensitivity, but is not included in the rates of either the Bonneville or region finances tables. Thus, the coal analysis impacts is appropriately described in the EIS. The commenter misunderstands the types of impacts that must be considered in an EIS under NEPA. Consistent with the Council on Environmental Quality's implementing Regulations for NEPA, the co-lead agencies considered environmental, social and economic effects. (See 40 C.F. R 1508.14). Specifically, [w]hen an environmental impact statement is prepared and economic or social and natural or physical environmental effects are interrelated, then the environmental impact statement will discuss all of these effects on the human environment. Id. Additionally, the high-quality information included in the EIS and known changes to the regional grid since the Northwest Power and Conservation Councils Seventh plan, need to be factored into the analysis, since they will have effects on the expected value of Federal generation in the future. Thus, the sensitivity analysis properly falls within the effects contemplated under NEPA.
6692	18	nina.englander@doj.state.or.us	Oregon Department of Justice	Power Replacement Costs Step 3 of the methodology for power and transmission analysis determines the need to develop new power resources to replace any reduced output from the hydropower system, and the associated costs of developing those resources.30 ODOE appreciates the detailed and robust analysis that the drafters undertook to analyze the potential need for new power resources to replace any reduced output from the hydropower system. ODOE does not identify here any particular concerns with this step of the analysis, and we appreciate that an effort was made to evaluate both the least-cost portfolio of replacement resources and a zero-carbon portfolio of replacement resources. ODOE does have concerns, however, with the identification of the estimated costs for potential power replacement resources. The primary concern that ODOE has is with reliance upon the NWPCCs Seventh Power Plan Midterm Assessment31 (published in February 2019) as the basis for determining the overnight capital cost of building new power resources.32 ODOE recognizes that the Draft EIS adjusted these numbers further to reflect real 2022 dollars, but we do not believe this accurately captures the rapid changes in technology costs occurring within the power sector. The Draft EIS seems to acknowledge this: Because only	Consistent with the comment, the EIS presents a range of replacement resource costs that would be needed to maintain regional reliability at the No Action Alternative level based on two resource portfolios: one that is based on renewable resources and another that is based on natural gas resources, which are generally the least cost means to maintain reliability (see Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS). The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options and changes in costs. As noted in the comment, to avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council (Council) in their 7th Power Plan (7th Power Plan, page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at 3-821 and Appendix H, Power and Transmission, at Section 2.2. The EIS uses the best available resource cost information from the Council to estimate the potential range in costs of these replacement resources. The basis for developing these portfolios may be found in Section 3.7.3.1, Methodology, and for Multiple Objective (MO) Alternative 3 specifically, Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the single mid-point was used in the CRSO EIS analysis there are resource cost uncertainties that could result in higher and lower cost outcomes for the MOs.33 Particularly as it pertains to estimated costs for the zerocarbon portfolios, ODOE is less concerned that actual resource costs could be higher than estimated, but we have significant concerns that actual costs might be lower than estimated. This concern grows the further into the future (e.g., beyond 2022) that any potential power replacement resources would need to be built. For example, Table 2-3 from App. H 34 is reproduced below: 30 Draft EIS at 3-819. 31 Available online: https://www.nwcouncil.org/sites/default/files/7th%20Plan%20Midterm%20Assessment%20Final%20Cncl%20Doc%20%232019-3.pdf 32 Draft EIS at Footnote 48, p. 3-835 and Appendix H, p. H-2-5. 33 Draft EIS at 4-385. 34 Draft EIS at Appendix H, p. H-2-6. 12 In particular, ODOE notes the capital cost estimate for solar at $1,350 to $1,500/kW. ODOE does not recommend a specific alternative cost estimate. ODOE is, however, including below a table developed by the National Renewable Energy Laboratory (NREL) for its 2019 Annual Technology Baseline35 that projects the future capital cost of solar out to 2050: NRELs forecast of capital costs for solar PV continues to decline significantly in the Low case and moderately in the Mid case. By 2032, for example, it appears that NREL forecasts solar PV 35 National Renewable Energy Laboratory, 2019 Annual Technology Baseline. Available online: https://atb.nrel.gov/electricity/2019/index.html?t=su 13 costs could be as low as $500/kW in the Low case, or approximately 60% lower cost than the low estimate provided for solar in the Draft EIS. Even in 2022, it appears that NREL forecasts a cost closer to $1,000/kW in its Low and Mid cases (approximately 25% less than the low estimate in the Draft EIS). We note that the Northwest Power Council also identified a further 10% to 15% reduction in solar capital costs just from 2018 to 2020.36 ODOE raises these issues here primarily because of the uncertainty involved around the timeline of implementing some of the measures evaluated by the various alternatives within the Draft EIS. For example, MO3 evaluates breaching the four Lower Snake River Dams. It is highly unlikely that this could occur by 2022 under any circumstance. A more robust analysis of the cost of potential power replacement resources in that scenario would consider a forecast of how power replacement costs would be likely to change some number of years into the future. A more comprehensive analysis would also utilize some method of portfolio optimization to identify a combination of complementary resources that could replace any reduction in output from the federal hydropower system, including targeted energy efficiency investments, demand response measures, and storage in addition to an evaluation of renewable generation technologies. Specific Recommendation: Final EIS must include a more robust power replacement analysis that includes the development of an optimized portfolio of resources that incorporates forecasted technology costs over the following time horizons: 2022, 2030, 2035, and 2040.	The statement in the comment that the EIS uses the midpoint resource cost estimate is consistent with the EIS methodology. To address uncertainty surrounding potential costs, the EIS included a range of resource costs from the Mid-term Update in the sensitivity analyses for each wholesale rate pressure analysis. To further address concerns about potential reductions in resource costs. consistent with the comment, publicly released draft information, such as updated prices for solar and battery storage, from development of the 8th Power Plan is included as rate sensitivities in the final EIS. In response to this comment from Oregon and other public comments, the final EIS will include an expanded description of how the potential replacement resource portfolios were selected for the EIS. Briefly, the EIS analysis ran trial studies of seven different replacement resources for each alternative that needed replacement resources to evaluate their effectiveness at lowering the LOLP relative to the cost for the need in each alternative. (See Section 3.7.3.1 in the draft EIS). The comment suggests that additional energy efficiency should be assumed in the EIS, beyond what is achieved in the Councils Plan. The EIS analysis considers that all energy efficiency assumed in the Councils 7th Plan is achieved. This assumption is appropriate and likely aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings form efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as in MO3. Finally, the Final EIS reflects potential changes to future costs in the rate sensitivity, considers updates to its resource optimization approach and describes the optimization in more detail. Finally, the EIS uses the best available resource cost information from the Northwest Power and Conservation Councils 7thPower Plan and Mid-Term update to estimate the potential range in costs of these replacement resources, with the exception of batteries which used newer sources, namely, 2018 and 2019 IRPs from Northwestern Energy and Puget Sound Energy. To further address concerns about potential reductions in resource costs, consistent with the comment, publicly released draft information, such as updated prices for solar and battery storage, from development of the Council's 8th Power Plan is included as rate sensitivities in the final EIS. The final EIS will include the de-escalating cost curves prepared by the National Renewable Energy Laboratory (NREL) that will be used by the Council in the 8th Power Plan. Based on responses to public comments, the final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. (See Chapter 3, Section 3.7.3.1).
6692	19	nina.englander@doj.state.or.us	Oregon Department of Justice	Customer Power Rate Impacts As noted in the introduction to this section of ODOEs comments, impacts to the power sector resulting from the alternatives discussed in the Draft EIS can be quantified in terms of cost. There are technically feasible options for replacing any reduction in power output from the federal hydropower system that results from this or any other process; the issue resolves itself as a matter of cost, and an allocation of those costs. BPA is required by the Northwest Power Act to provide preference and priority in selling power to consumer-owned utilities (including municipal utilities, rural electric cooperatives, peoples utility districts, and tribal utilities)37. These preference customers of BPA often purchase firm power from BPA, and many are full requirements customers that receive 100% of their power from BPA to serve retail customers. As a result, any costs of actions taken pursuant to the alternatives evaluated within the Draft EIS will impact these preference customers the most. In Oregon, consumer-owned utilities (preference customers of BPA) serve the most rural and lowest income areas of the state, which creates questions around how to equitably allocate the costs to achieve non-power objectives within the Columbia River System. This discussion should be included in the EIS. Step 5 of the methodology for power and transmission analysis evaluates the impact of each alternative on customer rates. As explained in the Draft EIS, this analysis of BPAs rates considers multiple variables, including: (1) the cost of potential replacement power resources and new transmission investments; (2) impacts to BPA revenues from surplus power sales and 36 Starrett, M., Solar, Battery Storage, and Solar + Battery Storage Reference Plants, Staff presentation to the Northwest Power and Conservation Council. October 8, 2019. See, page 8, slide 16, available online: https://www.nwcouncil.org/sites/default/files/2019_1015_p4.pdf 37 Draft EIS at 3-799. 14 transmission sales; and (3) the cost of any structural or operational measures within an alternative.38 To the extent that these variables result in net costs for the power customers of BPA, robust cost mitigation efforts should be considered that consider the potential inequities in how these costs are allocated across the region. Figure 3-165,39 as an example, illustrates how BPA spends every dollar of its power revenues during the BP-20 rate period from October 1, 2019 through September 30, 2021: As a self-funded government entity, BPA is required by law to sell power to its customers in a manner that reflects its actual costs. To develop its revenue requirement for serving its power customers, BPA must consider its program costs, debt payments, and other costs established through the ratemaking process (including the Residential Exchange program, power purchases, and the cost of transmission).40 On account of the scale of some of the costs associated with the alternatives evaluated within the Draft EIS, ODOE recommends that an analysis be conducted of 38 Draft EIS at 3-823. 39 Draft EIS at 3-805. 40 Draft EIS at 3-804. 15 how best to equitably allocate the costs across the region to achieve the non-power objectives sought by each alternative. Specific Recommendation: Update the cost analysis within the EIS to include an evaluation of how to equitably allocate the costs of achieving non-power objectives within the EIS.	Consistent with the comment, the EIS presents a range of replacement resource costs that would be needed to maintain regional reliability at the No Action Alternative level based on two resource portfolios: one that is based on renewable resources and another that is based on natural gas resources, which are generally the least cost means to maintain reliability (see Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS). The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options and changes in costs. As noted in the comment, to avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council (Council) in their 7th Power Plan (7th Power Plan, page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at 3-821 and Appendix H, Power and Transmission, at Section 2.2. The EIS uses the best available resource cost information from the Council to estimate the potential range in costs of these replacement resources. The basis for developing these portfolios may be found in Section 3.7.3.1, Methodology, and for Multiple Objective (MO) Alternative 3 specifically, Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS. The statement in the comment that the EIS uses the midpoint resource cost estimate is consistent with the EIS methodology. To address uncertainty surrounding potential costs, the EIS included a range of resource costs from the Mid-term Update in the sensitivity analyses for each wholesale rate pressure analysis. To further address concerns about potential reductions in resource costs. consistent with the comment, publicly released draft information, such as updated prices for solar and battery storage, from development of the 8th Power Plan is included as rate sensitivities in the final EIS. In response to this comment from Oregon and other public comments, the final EIS will include an expanded description of how the potential replacement resource portfolios were selected for the EIS. Briefly, the EIS analysis ran trial studies of seven different replacement resources for each alternative that needed replacement resources to evaluate their effectiveness at lowering the LOLP relative to the cost for the need in each alternative. (See Section 3.7.3.1 in the draft EIS). The comment suggests that additional energy efficiency should be assumed in the EIS, beyond what is achieved in the Councils Plan. The EIS analysis considers that all energy efficiency assumed in the Councils 7th Plan is achieved. This assumption is appropriate and likely aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings form efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as in MO3. Finally, the Final EIS reflects potential changes to future costs in the rate sensitivity, considers updates to its resource optimization approach and describes the optimization in more detail. Finally, the EIS uses the best available resource cost information from the Northwest Power and Conservation Councils 7thPower Plan and Mid-Term update to estimate the potential range in costs of these replacement resources, with the exception of batteries which used newer sources, namely, 2018 and 2019 IRPs from Northwestern Energy and Puget Sound Energy. To further address concerns about potential reductions in resource costs, consistent with the comment, publicly released draft information, such as updated prices for solar and battery storage, from development of the Council's 8th Power Plan is included as rate sensitivities in the final EIS. The final EIS will include the de-escalating cost curves prepared by the National Renewable Energy Laboratory (NREL) that will be used by the Council in the 8th Power Plan. Based on responses to public comments, the final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. (See Chapter 3, Section 3.7.3.1).
6692	20	nina.englander@doj.state.or.us	Oregon Department of Justice	The Oregon Department of Fish and Wildlife (ODFW) has participated in good faith as a cooperating agency in the EIS process since the summer of 2017, providing feedback in a timely manner despite difficult timelines. ODFW has actively reviewed documents, commented and made recommendations to the Action Agencies throughout the process. Active participation as a cooperating agency resulted in thousands of comments and recommendations across hundreds of versions of previous Draft EIS development components, very little of which has been incorporated into this Draft EIS. High-Level Draft EIS Concerns Purpose and Need The Draft EIS does not satisfy the purpose of the CRSO court-ordered NEPA process, which was to evaluate the large-scale project of the 2014 BiOp RPA and its alternatives. Judge Simon repeatedly emphasized that the goal of the EIS is to force the consideration of environmental impacts in the decision-making process. For example, the option of breaching, bypassing, or even removing a dam may be considered more financially prudent and environmentally effective than spending hundreds of millions of dollars more on uncertain habitat restoration and other alternative actions.41 The Action Agencies appear to believe that it satisfied the purpose of CRSO court-ordered NEPA process through its development and analysis of Multiple Objective 3 (MO3). However, MO3 was fundamentally deficient from its inception because it is a proposed action that includes both structural and operational measures that in some cases benefit but in other instances result in detrimental impacts to natural resources in a manner that masks the environmental impact of individual measures. For example, the Action Agencies selection of individual measures that are combined in MO3 obscures the actual beneficial environmental impacts to water quality, including anadromous fish species, of the option of breaching, bypassing, or even removing a dam that would have informed the public and decisionmakers as the Court had urged. Further, the Draft EIS summarily dismissed MO3 from further consideration during the Preferred Alternative selection process based upon the action agencies inclusion of meeting its agency statutory obligations in its purpose and need statement. NEPA is clear that an agency must analyze a reasonable alternative to its proposed action, even if it was outside of its statutory authority to implement. The Action Agencies inclusion of its statutory mandates in its purpose 41 NWF v. NMFS, 184 F. Supp. 3d 861, 942-43 (D. Or. 2016) (emphasis added). 16 and need statement resulted in precluding further analysis of that reasonable alternative, preventing public disclosure and discourse.	The co-lead agencies appreciate ODFWs participation as a cooperating agency in the NEPA process. In the development of this EIS, the co-lead agencies have complied with NEPA and its implementing regulations. The co-lead agencies have considered a reasonable range of alternatives developed to the meet the purpose and need and study objectives. Those alternatives included a broad range of operations and other measures, including breaching certain CRS project dams. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a substantial contribution towards recovery. Additionally, the co-lead agencies evaluated many different flow and spill levels and as well as seasonal patterns for when flows are enhanced or reduced. The Preferred Alternative represents an operation that provides a balanced approach between spring and summer flow and spill levels to benefit salmon and steelhead, while also providing benefits to resident fish in the upper portion of the Columbia Basin.
6692	21	nina.englander@doj.state.or.us	Oregon Department of Justice	Adequacy and Equity of the Development and Analysis of Reasonable Alternatives This Draft EIS does not contain a true anadromous fish-focused alternative. Early in the Draft EIS process, a suite of structural and operational measures were identified, some of which likely benefited anadromous fish survival and some of which likely decreased anadromous fish survival. The action agencies then chose and reassembled a subset of these measures into four multiple objective alternatives (MOs) without any quantitative or qualitative analysis of the individual measures. Failure to conduct analysis of individual measures effectively eliminated any understanding of the relative nature, magnitude or duration of any one measures impact of anadromous fish survival. The four MOs and the No Action Alternative were then analyzed both quantitatively and qualitatively. However, these analyses captured only the interacting effects of combinations of individual measures on the affected environment. Thus, the true efficacy of any measure meant to benefit anadromous fish was obscured and could not be considered. Although ODFW is not necessarily advocating for this particular alternative, an example of an environmentally preferred alternative that would likely avoid jeopardy of ESA listed anadromous salmonids, lead to recovery, and that was not analyzed as part of the Draft EIS process but should have been would contain the following measures (from Tables 2-7 and 29). Structural Measures: 1) Modify the upper ladder serpentine flow control ladder sections at Bonneville Dam 2) Expand network of Lamprey Passage Systems to bypass impediments 3) Modify turbine cooling water strainer systems to safely exclude Pacific lamprey 4) Modify turbine intake bypass screens that cause juvenile lamprey impingement 5) Modify existing fish ladders, incorporating lamprey passage features and criteria 6) Lower Snake River Breach a. Develop procedures to operate existing equipment during reservoir drawdown (Lower Granite, Little Goose, Lower Monumental, and Ice Harbor Dams) b. Develop contingency plans to address unexpected issues with drawdown operations (Lower Granite, Little Goose, Lower Monumental, and Ice Harbor Dams) Operational Measures: 1) Remove earthen embankments and adjacent structures, as required, at each lower Snake River Dam 2) Modify equipment and infrastructure to adjust to drawdown conditions at each lower Snake River Dam 3) Develop procedures to operate existing	The preliminary analysis of the Single Objective alternatives informed the combination of measures which make up the final range of alternatives for analysis in this EIS. The CRS is a complex system with competing authorities. As such, the co-lead agencies needed to develop reasonable alternatives that could be used to operate the CRS into the future. The Co-Lead Agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. All of the measures listed by the commenter were evaluated as part of the EIS, several of which were carried forward into the Preferred Alternative. Other measures were not carried forward into the Preferred Alternative, and Chapter 7 describes the rationale for developing the Preferred. The agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% Total Dissolved Gas (TDG) at all four lower Columbia River dams, plus draw down and the McNary flow target is reasonable given the unacceptable risks to public safety from such an alternative. For Power and Transmission, MO3 and Multiple Objective alternative 4 (MO4), individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 MW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				equipment during reservoir drawdown at each lower Snake River Dam 4) Develop contingency plans to address unexpected issues with drawdown operations at each lower Snake River Dam 17 5) Lower Columbia River Fish Passage Spill a. Spill through surface passage structures for steelhead overshoots, overwintering steelhead, and kelt b. Set juvenile fish passage spill to 125 percent TDG 6) Other Operational Measures. a. Strive to hold minimum 220 kcfs spring flow/200 kcfs summer flow at McNary Dam using upstream storage b. Reservoir drawdown to Minimum Operating Pool to reduce outmigration travel time (McNary, John Day, The Dalles, and Bonneville Dams) 7) Maintain all existing fish and wildlife mitigation programs This constitutes a reasonable alternative not analyzed in the Draft EIS, which is significantly distinguishable from the other analyzed alternatives. ODFW urges the action agencies to adhere to NEPAs mandate and incorporate review of this reasonable yet unexamined alternative.	In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. This potential alternative has not been evaluated for direct, indirect and cumulative effects to other resources. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), and also meets most of all the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply. It minimizing adverse effects to communities and the economy. The Preferred Alternative is likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6692	22	nina.englander@doj.state.or.us	Oregon Department of Justice	Adequacy and Equity of Water Quality Analysis The Draft EIS water quality analysis fundamentally failed to analyze and summarize environmental effects of water quality in a manner which allows the public or decisionmakers to understand the full range potential impacts to fish and fish habitats. The water temperature analysis focused solely on daily maximum temperatures, although important to fish and aquatic species, does not adequately inform environmental consequences. The water quality analysis does not adequately address the following environmental information: 1) The full range of daily water temperature fluctuation across alternatives, including average daily mean and daily minimum temperatures. 2) The water temperature benefits likely to occur under MO3 particularly as they relate to the enhance ability for summer cold water releases from Dworshak Reservoir and the restoration of ecological functions such as reconnection of hyporheic flow, floodplain creation, development of riparian habitat to cool the lower Snake River. 3) The water temperature benefits likely to occur under MO3 as result of less solar heat accumulation with conversion from four reservoirs to restoration of approximately 140 miles of riverine habitats. 4) The water temperature impairments likely from measures to increase reservoir forebay elevations, increasing reservoir surface area and decreasing water travel time which are found in all Alternatives including the PA. 5) Opportunities to use cooler water from reservoir depth to reduce fish ladder water temperatures at John Day dam and other lower Columbia River projects that demonstrate mild stratification from the Corps temperature monitoring data. 6) Mitigation actions that could be employed during drought or low water years to prevent fish kills the nature of those that occurred during the summer of 2015. The Final EIS must include a more robust water temperature environmental consequences analysis that describes and contrasts water temperature impacts in a meaningful way considering the affected resources including anadromous fish. The Final EIS must also include a 18 contingency plan to manage water temperatures during drought years, low flow years, and during periods of high temperature to avoid future fish kills such as that which occurred in 2015.	The co-lead agencies chose to use the daily maximum water temperature metric in the analysis since most state water quality standards for water temperature are based on this metric. This temperature analysis evaluates the important factors that impact temperature and is similar to TMDLs and other efforts in the region. Fish appropriate water quality metrics were provided for incorporation into COMPASS and CSS modeling and other analysis to evaluate the impacts to anadromous fish. The fish team also used water quality outputs to qualitatively examine effects to fish species based upon known relationships between water temperatures and fish responses where quantitative models were not available. In this way the team was able to discuss effects on time and locality scales that may not be detected by the models. Predicted water temperatures under MO3, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. In addition, riverine processes would be restored. This is described in Chapter 3-4 and Appendix D. Regarding fish ladder water temperatures, reservoir water temperature data was used to determine the potential for water temperature improvements in the lower Snake River fish ladders. Cooling water pumps have been installed at Lower Granite and Little Goose adult passage ladders to reduce temperature differentials between ladder and river and to reduce thermal stress during upstream passage. Additional considerations at other locations are included in the EIS. Regarding mitigation actions that could be employed during drought or lower water years to prevent fish kills, an adaptive management plan has been developed for this EIS that captures those potential actions. That information can be found in Appendix O. The CRS is a complex system with multiple, sometimes competing, congressionally-authorized purposes. The Purpose and Need Statement and the objectives developed for this EIS reflect these multiple purposes, as do the alternatives developed to meet them. This EIS was developed to evaluate the operation and maintenance of the CRS system over the next 20 years, with the expectation that the co-lead agencies will continue to meet the multiple, authorized purposes until directed differently by Congress. Although fish and wildlife conservation is one of the authorized purposes, it is not the only purpose, and the co-lead agencies must balance all resources. The analysis of the multiple objective alternatives reflect these trade-offs and have allowed the co-lead agencies to understand the effects of emphasizing some purposes over others in order to find the most acceptable balance for future operations. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. As required by NEPA, the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapter 3, summarized by resource and alternative in Table 3-1, and once again presented for comparison in Table 7-1. Effects of the Preferred Alternative can be found in Chapter 7. Effects specific to anadromous fish are described in Section 3.5.3 and Chapter 7. Table 3-61 compares expected survival by alternatives, and Table 3.62 provides a comparison of the alternatives specific to anadromous fish.
6692	23	nina.englander@doj.state.or.us	Oregon Department of Justice	Adequacy and Equity of the Climate Analysis The Draft EIS analysis misrepresents the impacts of climate change and does not identify sufficient measures to avoid and mitigate impacts. The Draft EIS Climate section asserts that future conditions will include reduced snowpack, increased water temperatures and lower summer discharges, and a likely increase in the frequency of cumulative daily temperature exceedance events. However, these climate impacts are not integrated into and should be in the descriptions of water temperature impacts described in Chapter 3, the Affected Environment and Environmental Consequences sections. For example, the Draft EIS states, Air temperature is projected to be warmer throughout Region C and D (Section 4.1). Warmer air temperature combined with projected reduced summer and fall flow volume (Section 4.2) will likely lead to increased riverine and reservoir surface water temperature but does not discuss how these climate conditions will exacerbate water temperatures that already exceed water quality standards for temperature (68 F) approximately 257 times each summer on average in the Lower Columbia River as measures at the forebay of McNary, The Dalles, John Day, and Bonneville Dams under the No Action Alternative. The Draft EIS makes no further distinction between the remaining alternatives as to how this may differ. In actuality, anadromous salmonids, fish that have evolved to cold water habitats, will be exposed to more individual extreme water temperature exceedances or more cumulative exposure to less severe water temperature exceedances can and will be negatively impacted a survive less The Draft EIS states, Historical water temperatures have already approached lethal limits for adult steelhead in the upper Snake and middle Columbia Rivers (Wade et. al 2013). Thus, even minor increases in thermal exposure put some of these populations above lethal limits. ODFW agrees, and also asserts that that this is likely to occur with greater regularity as the effects of climate change persist in the Columbia Basin. However, this connection between climate impacts and historic water temperature problems is not adequately described in the Draft EIS. From the perspective of anadromous salmonid survival any alternative that does not include measures to mitigate excessive water temperatures will result in sub-lethal effects (compromised fitness) or direct lethal mortality. Further, the PA analysis described in Chapter 7contains no mention of the effects of increased water temperature on fish populations, particularly the effects caused by climate change. Finally, the Draft EIS does not include a thermal emergency contingency plan. The Draft EIS must anticipate thermal emergencies and provide a plan to mitigate such events. The Final EIS must include that plan to meet the requirements of NEPA.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The co-lead agencies agree with your concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used the best information and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. The study results indicate that the operations of the CRS do impact water temperature but the CRS has limited ability to reduce temperatures in the lower Snake and Columbia rivers outside of Dworshak operations. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; climate change will stress the system even further. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. Therefore it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). Regarding mitigation actions that could be employed during drought or lower water years to prevent fish kills, an adaptive management plan has been developed for this EIS that captures those potential actions. That information can be found in Appendix O. Regarding a thermal emergency contingency plan, the EIS is intended to evaluate multiple alternative ways of meeting a purpose and need for an action. The alternatives and analysis metrics, such as temperatures in different water year types, were developed for this purpose. Scenarios such as a "thermal emergency" in a specific year would be part of the adaptive management through existing forums such as the Technical Management Team.
6692	24	nina.englander@doj.state.or.us	Oregon Department of Justice	Adequacy and Equity of the Socioeconomic Analysis The Draft EIS includes an inequitable economic analysis of climate change. The Draft EIS goes into an extremely detailed future looking view of how climate change and the regions efforts to decrease carbon heavy power production such as coal and gas generation facilities will severely 19 exacerbate power reliability and replacement cost under MO3 and MO4. At the same time the Draft EIS fails to provide the same, or any, analysis for how climate change will impact salmonid survival, and what those impacts would have on regional cultural and socioeconomic resources. The Draft EIS did not include a socioeconomic analysis of recreational fisheries. Further, the Draft EIS includes an inequitable economic analysis of commercial and tribal fisheries that greatly undervalues these fisheries in geographic scope and current economic value. The Draft EIS fails to translate any of the changes in relative fish abundance across alternatives into comparable fishery socioeconomic gains or losses for the public and decisionmakers consideration. The socioeconomic elements of the Draft EIS fail to address or employ widely-accepted professional economic standards to ensure a thorough, objective, and transparent evaluation of the Draft EIS alternatives. These standards are defined in court interpretations of the National Environmental Policy Act, the Corps guidance documents for socioeconomic analyses, and other socioeconomic analysis process standards42. Consequently, there are severe, systemic gaps in the socioeconomic analyses of the Draft EIS that inaccurately represent regional effects of alternatives with respect to recreational, commercial and tribal fisheries in a manner that prevents reasoned decision-making. Specifically, the Draft EIS fails to: 1) Make use of all the available, relevant, accurate, and reliable socioeconomic information. 2) Make a substantial, objective effort at studying, analyzing, and evaluating all the socioeconomic issues relevant to the actions considered. 3) Account fully for the socioeconomic importance of ecosystems and ecological risks. 4) Consider equally both monetized and non-monetized effects. 5) Examine the multiple socioeconomic consequences of the preferred alternative and other alternatives. 6) Fully disclose all relevant information, and provide full transparency to the decisionmaking process, to enable the public and decisionmakers to understand the rationale for selecting the preferred alternative. The Final EIS must be modified to include all of the available socioeconomic information as opposed to the Draft EISs current limited analysis. For example, the Draft EIS reports current 42 Principles and Requirements for Federal Investments in Water Resources (pdf) Interagency Guidelines (pdf) Department of the Interior. 2015. Agency specific procedures for implementing the Council on Environmental Qualitys Principles, Requirements, and Guidelines for Water and Land Related Resources Implementation Studies Executive Order 12866. 1993. Regulatory planning and review Office of Management and Budget. 2003. Circular A-4: regulatory analysis 20 gross domestic product (GDP) and full-time equivalent (FTE) fishery values for Oregon and Washington. But those numbers reflect only the current state and value of salmon fisheries in Oregon and Washington, which, due in large part to negative impacts from the CRS Operations, are operating under a constraining set of rules that severely limits harvest. Given that other sections of the Draft EIS evaluate alternative futures, it is equally warranted to scale fishery economic values to that of a future with healthy salmon populations and what that would mean to the fisheries GDP and FTEs of the states. Hatchery contributions in the region are significant, but are not considered in the analysis. Both ocean and in-river fisheries that depend on the health of Columbia River salmon stocks provide millions of dollars in economic activity annually. From 2012-2015, Gislason et al. (2017) estimated that commercial and recreational salmon fishing accounted for an annual average of $1,996 million in GDP and supported 26,700 FTE jobs in the U.S. economy. The Draft EIS simply does not provide an equitable economic analysis of fisheries as a commodity. If the Action Agencies had analyzed a true anadromous focused alternative, as has been repeatedly suggested by ODFW, then increased regional employment and economic value would be substantial. Furthermore, recreational fishing is combined with other recreational activities into a single metric in the Draft EIS socioeconomic analysis of recreational use, and thus provides no measure of the economic impacts of different alternatives on recreational fishing. For the states with fisheries most impacted by CRS operations, recreational angling for salmon accounted for an annual average $238 million in GDP and 3,160 FTE (Washington) and $173 million in GDP and 2,850 FTE (Oregon) (Gislason et al. 2017). Likewise, the Draft EIS lacks an economic analysis of river and ocean commercial fisheries and tribal fisheries. Commercial salmon harvest accounted for an annual average $241 million in GDP and 3,090 FTE (Washington) and $55 million in GDP and 910 FTE (Oregon) (Gislason et al. 2017). Beyond economic activity, salmon are profoundly important for the native peoples of the Northwest. As co-managers of the salmon resource, the non-monetary tribal interests must be an integral part of this discussion. As stated previously, fisheries can be further constrained by listed species, depending on the actions proposed in the alternatives. Given the significant contributions of	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia Basin in still under development and was not available for us in this study. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). Chapter 7, Preferred Alternative, describes the process to select the Preferred Alternative. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations under MO3 would have negligible to minor changes from the No Action Alternative. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. For MO1, MO2, MO4, and the Preferred Alternative, the recreational fishing evaluation describes the impacts by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The Fisheries Section 3.15 as well as Section 3.17, in particular, include discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries Section 3.15.2.1, which includes sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries.

				commercial, recreational and tribal fisheries to regional economies, a fishery-specific economic analysis should be given equal weight with other commodity-specific analyses in the Draft EIS. These above-described issues with the Draft EIS prevent reasoned decision-making.	
6692	25	nina.englander@doj.state.or.us	Oregon Department of Justice	The Draft EIS fails to ensure the professional and scientific integrity of the discussions and analyses. Where high quality scientific evidence is presented, it is commonly caveated based primarily on speculation and is discounted in favor of less scientifically-defensible information. 21 This presents a subjective view and ultimately a biased representation of the state of the science.	NEPA requires Federal agencies to assess the environmental effects of their proposed actions prior to making decisions. The Draft EIS provides a comprehensive and unbiased analysis of the effects of the No Action Alternative, the Multiple Objective alternatives and the Preferred Alternative, while also considering cumulative effects within the basin. The co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as cooperating agencies, and over 30 of those invited agreed to participate. Staff from the cooperating agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation, maintenance and configuration of the dams in the CRS system. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The Draft EIS was subject to two internal agency reviews by Corps of Engineers reviewers not involved in the development of the document. Then the document, analysis, and modeling were reviewed following an Independent External Peer Review process. The Corps hired an independent panel of experts to review and provide feedback on the EIS and models used in the analysis. The final IEPR report will be publicly available.
6692	26	nina.englander@doj.state.or.us	Oregon Department of Justice	A few examples are noted as follows. The Draft EIS uses two quantitative modeling approaches to predict survival benefits or decrements across alternatives: (1), the Northwest Fisheries Science Centers (NWFSC) Comprehensive Passage (COMPASS) and Life-cycle models and, (2), the Comparative Survival Studys (CSS) Cohort and Life-cycle models (CRSO-84, CSS Annual Report 2017). Despite the fact that both approaches have been reviewed and scrutinized extensively, the discussion and summarization of the results of the two models are presented in a biased manner: (1) Model results between models (e.g., NWFSC and CSS) are not given fair and equitable consideration; (2) CSS Model results are presented with misleading and unnecessary qualifier statements while output from NWFSC models are represented as fact with no qualification and no meaningful discussion of assumptions; (3) Fish modeling results are presented in a biased manner, use unnecessarily charged language, and are generally not presented in a fair and transparent manner particularly when modeling results differ between models. Examples of this bias become particularly pronounced as the effect descriptions in Chapter 3 are characterized in Chapter 7 as the justification for choosing the PA. The Draft EIS employs a TDG tool, a model used to quantify exposure of out-migrating salmon and steelhead to total dissolved gas (TDG) and the contribution of TDG to mortality irrespective of other sources. The model has not been peer-reviewed or otherwise scrutinized in any meaningful way, yet output, particularly related to reach-average exposure, is nonetheless presented as reputable. Model parameters are based almost solely on laboratory studies conducted decades ago. It strains credulity that these parameters, and consequently the mechanisms that drive output, would realistically represent the real-world effects of variation in TDG. Further, the model is highly dependent on or sensitive to uncertain parameter assumptions (e.g., TDGcrit. from laboratory studies), where the unsubstantiated selection of values can have a disproportionate effect on outcomes. The authors of the Draft EIS point to some of these insufficiencies briefly, but then include estimates as though TDG tool were a completely qualified model upon which decisions can be made. The Final EIS should eliminate the use of the TDG tool in its analysis of fish survival. The Draft EIS fails to consider in any meaningful way empirical field observations of TDG impacts to fish migrating in-river through the Snake and Columbia Rivers collected over two decades as part of the well-established Smolt Monitoring Program (SMP; http://www.fpc.org/smolt_home.html).	The co-lead agencies do not agree that the CRSO EIS presents information regarding the CSS Life Cycle model in a biased manner. Since the CSS model supports the choice of the Preferred Alternative, the co-lead agencies have utilized the outputs from CSS, in part, in order to make the selection of the Preferred Alternative. Most of the ecological models implemented for the CRSO EIS have entered into a peer review process using the IEPR process, although evaluations were not yet available at the time the draft CRSO EIS was distributed. These include the University of Washington (UW) TDG model. As there is no empirical data for the 125% TDG spill targets at all flow levels, we felt the need to model this highlight possible exposure levels. The UWs TDG model was already built, so we used that. This model does incorporate empirical data on fish behavior and survival, but the TDG-survival relationships are (necessarily) based on laboratory relationships. Because of the limitations of current models related to TDG and survival, those outputs from the TDG model were not used for decision making purposes. Experiments with confined fish will not accurately represent free swimming fish, which we know from telemetry studies of both adults and juveniles change depth regularly and can spend significant time at compensating depths, which reduce gas loading. The IEPR process should provide insight on the UW TDG model.
6692	27	nina.englander@doj.state.or.us	Oregon Department of Justice	As noted above, the Draft EIS relies heavilyin modeling or generally in discussionon information from laboratory or in situ mesocosm experiments. While useful in shedding light specific mechanisms underlying a response, scaling results from such experiments to the natural environment where conditions vary in time and space can be, and commonly is, tenuous. With this in mind, it is all the more surprising that empirical information from the SMP was discounted in the Draft EIS. Through the SMP, the action agencies have funded decades of monitoring at projects within the lower Snake and Columbia Rivers in order to observe for signs of GBT in fish as a means of identifying if adaptive managements changes to spill operations are necessary to avoid adverse impacts to fish. This federally funded program constitutes the best available data characterizing real-world population-level effects of variation in TDG on anadromous fish. The final EIS must consider 22 thoroughly this information to provide a more accurate picture of the effects of TDG on lifecycle survival across alternatives.	TDG levels are regulated under the Federal Clean Water Act, and administered by the States. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a 5-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. There is considerable uncertainty in the effects; and therefore, monitoring was required by the states and EPA to ensure any adverse effects are detected and allow for adaptive management. Migrating salmon and steelhead may spend sufficient time at depths that will compensate for the high gas levels. However, fish and other organisms that spend extended times in less than a few meters of depth are at high risk. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. Please see Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The co-lead agencies are aware of the Smolt Monitoring Program gas bubble trauma monitoring and recognize that it will be valuable tool for adaptive management as we implement the Preferred Alternative. While we have seen 125% or even greater TDG in the river in past years, it has been due to high flow events that forced spill due to limited powerhouse capacity. The river conditions will be different in the Preferred Alternative with higher TDG levels over much longer period of time and a smaller volumes of water in the river, and so we felt the need to model this and shed some light on possible effects. The UWs TDG model was already built, so the co-lead agencies utilized it for the analysis. This model does incorporate empirical data on fish behavior and survival, but the TDG-survival relationships are (necessarily) based on laboratory relationships. We agree with the comment that scaling results from such experiments to the natural environment where conditions vary in time and space can be, and commonly is, tenuous. The key component of this issue is understanding smolts exposure to TDG.
6692	28	nina.englander@doj.state.or.us	Oregon Department of Justice	The Draft EIS includes inaccurate analysis of environmental effect because it arbitrarily ties discontinuation of Lower Snake River Compensation Plan hatchery releases to implementation to MO3, which is then argued will create a survival decrement for naturally produced Snake River salmonids and applied as a predator swamping impact. This is a false premise for several reasons: (1) The Lower Snake River Compensation Plan is direct mitigation for the effects of the Snake River Dams. Even if a breach alternative were implemented, it would likely be years before breaching occurred and longer still for the full impact of these dams to be abated; (2) Implementation of an MO3 style breach alternative would require the action agencies to seek congressional authorization and funding, and a supplemental EIS would likely have to be developed. It is implausible that no mitigation package would be designed in that instance to maintain all sectors of society during, at the very least, the transition period to when one or more dams are removed. Specifically, it is highly unlikely Lower Snake River Compensation Plan hatchery releases would be discontinued abruptly as language in the Draft EIS asserts. Further, a period of monitoring to demonstrate naturally-produced fish abundances were actually increasing to levels that would allow limiting hatchery supplementation would be needed; (3) If the Lower Snake River Dams were breached, the lower 140 miles of habitat would be converted from a reservoir habitat that supports nonnative predatory fish species such as bass, walleye, and channel catfish to a riverine habitat type that is unsuitable for these predators. Thus, population abundances of nonnative predatory fish species would decrease, reducing exposure to predators, and likely mitigating and predator swamping effect; and (4) there are other effects of breaching of the four lower Snake River dams that would likely protect migrants from any predator swamping impact. Fish travel times are predicted to decrease substantially under MO3, further limiting exposure to both fish and avian predators. Also, according to CSS modeling, smolt to adult return rates under MO3 are predicted to exceed the level necessary to achieve generational increases in abundance. Therefore, any predator swamping effect would likely be temporary and attenuate as productivity accrues. This is important to consider given that any potential reduction in hatchery production would be gradual, as noted above. Given these points, the certainty of the predator swamping argument espoused in the Draft EIS is incomplete, if not misleading, and should be tempered or removed.	The Draft EIS acknowledges that with breaching of the lower Snake River dams in MO3, there would no longer be an obligation to fund the Lower Snake River Compensation Plan, which accounts for much of the hatchery production in the basin, other mitigation activities could be adjusted, and transportation of Snake River salmon and steelhead would no longer be possible. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. As stated on page 3-548, the co-lead agencies recognize there would be transitional needs that would be addressed through mitigation and adaptive management. The fish models are based upon data collected from past fish runs and there is no data available to inform an quantitative analysis for wild fish in the absence of hatchery fish. The co-lead agencies took a qualitative approach to inform the reader of other factors that could affect salmon but acknowledged the magnitude of those effects is not known. The Draft EIS (Page 3-550) objectively presents these factors and discusses the tradeoffs, including: 1.) the predators that remain after dam breach would be mostly native fish adapted to riverine systems and there would be lower predation by non-native reservoir fish; 2.) decreased travel time through the corridor would reduce avian and piscine predation; 3.) the reduced predation risk may be offset by a reduction in hatchery fish and lower predator swamping effect. A summary of this qualitative discussion is provided for the reader for each Snake River species.
6692	29	nina.englander@doj.state.or.us	Oregon Department of Justice	The Draft EIS suggests that after independent review (IEPR) of the NWFSC and CSS approaches to modeling, changes in conclusions may be reflected in the Final EIS and ROD (the similarities and differences in the two CSS models as well as COMPASS will be the subject of IEPR, the results of which will inform the final version of this EIS.). This would presumably occur without public or cooperating agency review and thus would place interpretation of findings from the IEPR and modification to the EIS at the sole discretion of the action agencies. This is antithetical to a fair and transparent process.	The IEPR process involves addressing all IEPR panel comments and all the comments and their resolutions will be publicly available. For this EIS, any comments and resolutions regarding the NMFS and CSS models are coordinated with NMFS and Fish Passage Center. In compliance with NEPA, the Final EIS would be published in the Federal Register, and the agencies would refrain from making a decision for a minimum of 30 days. During this time, the public may submit comments to the co-lead agencies for consideration in their Record of Decision. Ultimately, the co-lead agencies, as lead agencies, have final responsibility for the analysis in the draft and final EISs and the decision made in ROD.
6692	30	nina.englander@doj.state.or.us	Oregon Department of Justice	Language in the Draft EIS states, These eddies can adversely affect downstream travel time and in-river survival and are not accounted for in the models during low flow conditions. Consequently, to some degree both models may have the potential to overestimate improvements in juvenile survival, travel time, and SARs. Eddy formation would not be new under MO4; 23 Eddies form under current conditions. So, any deleterious effects due to eddies would be inherent in fitted model coefficients. Thus, models would not overestimate survival benefits due eddy formation specifically. Ultimately, eddy formation occurs in natural riverine habitats and any eddies that occur at CRS projects do not delay downstream travel times in any measurable way.	It is very much the case that eddies and non-uniform tailrace circulation is known to occur in the tailraces of dams under certain conditions. The Corps has funded creation of scaled physical models at the Engineer Research and Development facility in Vicksburg, MS, to carry out dye studies to help identify optimum spillbay and turbine balances under a range of flow conditions. In addition, 3D computational fluid dynamics models have been used at some of the CRS dams. The percentage of spill called for under MO4 would be in the high range of recently observed conditions during high flow years, and would typically exceed the range of spill during lower flow years, so there are few real world observations. Results from the dye studies at physical models allow us to qualitatively describe formation of eddies under this proposed range of conditions.
6692	31	nina.englander@doj.state.or.us	Oregon Department of Justice	Mitigation As participant in the development of the CRSO EIS as Cooperating Agency, the ODFW repeatedly recommended the following list of mitigation measures to Avoid, Minimize, Rectify, Reduce, or Compensate for environmental impacts to anadromous fish from the proposed CRSO structural and operational measures: 1) Install Passive Integrated Transponder (PIT) detector arrays at all project spillway weirs and other undetected passage routes as technology allows. 2) The Action Agencies should immediately fund or conduct lethal removal of any California or Steller Sea lion predating on salmonids or sturgeon at passage pinch points such as Bonneville Dam. 3) Optimize dam flows for White Sturgeon spawning and early life stage survival. 4) Reduce load following limited to +/- 5%. 5) Develop contingency operations to increase both juvenile and adult fish survival during drought, low flow years, or years of excessive water temperatures similar to 2015. 6) Construct and operate cool water intakes in the forebay of John Day dam to cool fish ladder temperatures during high water temperature periods. 7) Change FRM to make more water available to fish (relax rule curves to manage towards normative hydrograph). 8) Mimic natural hydrograph (ops) (including in the estuary). 9) Build secondary fish ladders at Lower Granite and Little Goose dams to facilitate year around volitional fish passage during periods when the primary ladders are dewatered for annual maintenance. Design secondary ladder entrances to minimize adult delay during high spill operations. 10)Maintain less than 1-degree Celsius water temperature differential between fish ladders and tailraces for all CRS projects. 11)Modify CRS project powerhouse intake fish screens to reduce lamprey impingement. 12)Spill Increase to maximize SPE (shouldn't change hydrograph) to improve juvenile fish passage. 13)Cease juvenile fish	NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The co-lead agencies, in coordination with technical teams, including the cooperating agencies, compiled lists of all potential mitigation measures. Then, in comparison of the effects of each alternative to the No Action Alternative, highlighted where effects were minor, moderate, and major adverse effects. If adverse effects were negligible or minor but otherwise not measurable, and the resource did not otherwise have institutional or legal significance (i.e. wetlands), then mitigation was not proposed. If, when compared to the No Action Alternative, there were moderate or adverse effects, the teams developed a mitigation tool box (Appendix R, Part 3), which also presents rationales for not carrying forward mitigation measures. The commenter's proposed mitigation measures do not, however, appear to offset impacts associated with action alternatives. These were proposed in the workshop process and not selected because they did not offset identified effects of the Multiple Objective alternatives, and were accordingly not carried forward into the Preferred Alternative.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				transport systems and focus on improving in-river juvenile salmonids survival. 14)Optimize spill patterns at each project. This would require conducting deferred maintenance and repairs at The Dalles project to allow for full operation of spillbay operations. 15)Provide volitional passage and reintroduce anadromous fish above barriers when and where appropriate within the Columbia Basin. 24 16)Develop and implement environmental flow operations to provide periods of overbank flow when and where appropriate. 17)Expand Albeni Falls flow operations to expand protections for downstream Chum operations below Bonneville. 18)Increase opportunities for selective flow augmentations from storage reservoirs to benefit flow and water temperatures to increase anadromous fish survival. 19)Maximize storage of cold water at DWA, LIB and CJO projects for later summer flow augmentation. 20)Minimize reservoir operating elevations and viability operations to minimize reservoir surface area and fish travel time through reservoirs. 21)Reduce tailrace water elevation fluctuations due to load following (for sturgeon this would be directed to early life stage development time). 22)Increase likelihood of refill at storage projects that provide downstream water temperature management. 23)Increase shoreline vegetation for habitat and shading. 24)Implement deeper (existing) storage reservation diagrams to reduce FRM draft. 25)Investigate development of guide\ curves to avoid situations where heavy spill has to occur in the spring to meet FRM requirements. Concept would be to have a guide curve that is forecast based (to only be used in high water supply situations) to allow for earlier draft than the current SRDs. 26)Change seasonal/monthly turbine operations/priorities to change temperature mixing for cooling. 27)Repair and reconfigure stilling basins (project specific) to higher elevation/less depth for plunging flows to limit TDG. 28)Install deterrents to fish entrance of draft tubes when not in operation 29)Reconnect mainstem and off channel habitats. 30)Restore mainstem habitat through increased habitat complexity (rapid, riffle, run, pool), shallow water rearing habitat connectivity, temperature reduction, riparian function restoration, restore ecosystem processes. 31)Decrease White Sturgeon habitat fragmentation through dam passage improvements and/or dam removal. 32)Develop strategies to rebuild and/or augment fish ladders to promote volitional sturgeon passage. 33)Develop operational plans to strategically draw down reservoirs to minimize absorption of solar radiation and minimize volume of reservoir habitats that favor exotic predatory fish species. 34)Expand wire arrays to minimize avian predation at project tailraces. 35)Install wire array to dissuade avian predation at McNary 36)Modify project operations to allow larval lamprey (ammocoetes) in shallow water rearing areas to safely move to deeper water as water surface elevation drops. Unfortunately, none of these recommendations appear as new mitigation measures in Mitigation Chapter of the Draft EIS. These are important mitigation opportunities to effectively offset 25 many of the unintended consequences to anadromous salmonids that would occur as a result of implementation of the structural and operational measures currently proposed in the Draft EIS. ODFW urges the action agencies to incorporate of these mitigation measures as part of the Final EIS.	
6692	32	nina.englander@doj.state.or.us	Oregon Department of Justice	The Preferred Alternative (PA) does not meet the purpose and need for the proposed action. Specifically, the Draft EIS purpose and need states, In addition, the co-lead agencies are responding to the Opinion and Order issued by the U.S. District Court for the District of Oregon such that this EIS will evaluate how to insure that the prospective management of the System is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of designated critical habitat, including evaluating mitigation measures to address impacts to listed species. The Draft EIS claim, Operations intended to benefit anadromous and resident fish should contribute to the survival and recovery of ESA-listed species. Yet neither of the quantitative fish models supports this assertion (particularly when climate change is considered). In fact, both approaches to modeling alternatives predict anadromous Snake River ESA-listed yearling salmonid smolt-to-adult return (SARs) survival rates below that necessary to avoid jeopardy and move toward recovery. Specifically, CSS analyses predict the PA will be deficient, in terms of average Snake River yearling Chinook life-cycle survival (~2.7% SAR) relative to that necessary to facilitate recovery (2-6% SAR range, averaging 4% SAR). The NWFSCs life-cycle model predicts the PA will underperform more severely for Snake River yearling Chinook Salmon survival (<1.0% SAR) falling far below not only what is necessary for recover, but also the rate of adult return required to avoid population declines (2% SAR). This is true even when output from this model is scaled to mimic latent effects (1.12% SAR with a 50% adjustment). Where other species and stocks were modeled, or where surrogates were considered in lieu of direct estimates, the PA similarly fell short of the rate of adult return likely necessary for recovery or to avoid generational decreases in abundance.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the purpose and need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead Agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. For additional information on the alternatives development, see Chapter 2 and Appendix A, which explains why single-objective alternatives were not carried forward for detailed study in the EIS. It should be noted that the 2-6% Smolt-to-Adult return (SAR) target referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the Preferred Alternative analysis, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
6692	33	nina.englander@doj.state.or.us	Oregon Department of Justice	Failure to Disclose and Analyze Environmental Effects of a Preferred Alternative Beyond Year One Operation There is a fundamental disconnect between the time period of analysis cited in the Draft EIS (e.g., likely environmental impacts over a 25-year period) and the description of the PA (only one year of operational measures clearly described with subsequent years operations dependent upon adaptive management that appears to allow significant variations in operation not analyzed in the Draft EIS). This disconnect is compounded by language in Appendix R that inadequately describes adaptive management (presumably operation in years 2-25). In other words, Appendix R describes adaptive management and suggests the PA could be fundamentally changed as opportunities are presented. Yet there is no description of what these opportunities might be or 26 what operational changes may be implemented; however, this Draft EIS also includes a description of environmental consequences of the Preferred Alternative. So which is it? Have the action agencies failed to accurately analyze the likely environmental impacts of the PA (i.e., misrepresented environmental impacts for year one only as opposed to 25 years of such operations), or does this Draft EIS fail to identify and disclose to the public what operations and measures were analyzed as occurring in years 2-25 in the PA? This PA appears to be that of a programmatic EIS, but there is no acknowledgment by the action agencies that site-specific analysis must be conducted when more concrete operations and measures are identified. In short, the action agencies have analyzed only the impacts of a single year of proposed operations. This was done without apparent consideration of future check-points or any proposals for supplemental analysis to assess environmental impacts if and when operations or structural measures are manipulated in future years. As discussed above, given the Action Agencies failure to identify the environmental impacts of individual measures or structural changes, this Draft EIS does not provide typical bookends to allow such adaptive management in the future absent supplemental environmental analysis.	The effects of the Preferred Alternative are described for a 25-year period of analysis, not a single year of operations. If it is determined based on new information that actions should be modified as part of an adaptive management process, the co-lead agencies will review the change being considered to determine if the effects are described in this EIS. Depending on the change being considered, an updated Record of Decision may or may not need to be issued based on the analysis in the EIS. If the the expected effects are not described in the EIS, then it may be necessary to prepare a supplemental NEPA document to evaluate the proposed change in accordance with the Council on Environmental Quality's Regulations for Implementing the Procedural Provision of the National Environmental Policy Act (40 C.F.R. 1500-1508).
6692	34	nina.englander@doj.state.or.us	Oregon Department of Justice	NEPA Process Irregularities Chapter 1 and 2 of the Draft EIS describe how the Draft EIS will use descriptors such as no effect, marginal effect, minor effect, and major effect to characterize the magnitude, duration, and severity of environmental consequences. Yet Chapter 7, abandons use of these descriptors as effects are described to justify the choice of the PA and, in particular, justifying why other alternatives or measures in other alternatives are discounted. ODFW believes the Final EIS must use consistent language when discussing alternatives	The Co-Lead agencies agree that consistent language should be used when discussing alternatives and updated Chapter 7 to ensure consistent use of descriptors of effects.
6692	35	nina.englander@doj.state.or.us	Oregon Department of Justice	Recreational fisheries socioeconomic analysis is absent from the PA analysis. The economic contributions section of the PA is a brief summary of previously developed regional economic analyses and lacks any recent or current analysis. Consequently, this section is not based-upon sound science and is overly general, not being specific to the study area. Further detail and context are needed for the reader to be able to interpret this summary and compare these studies while understanding the key assumptions specific to each without having to solely rely on dated analyses	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The analysis in Chapter 7 incorporates and relies upon the analysis in the previous chapters. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					For the effects on recreational fishing under MO3 along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting tourism businesses. For MO1, MO2, MO4, and the Preferred Alternative, the recreational fishing evaluation describes the impacts by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
6692	36	nina.englander@doj.state.or.us	Oregon Department of Justice	There are terminology errors in the Passive Use Values Sections that should be corrected. Clarifications are made in the page specific comments. The key issue is the interchangeable use of the terms "passive use" and "non-use values". These types of values are different and using the same term for them interchangeably is incorrect and confusing. There are also quite a few misuses of the term Total Economic Value (TEV), which by definition, should include non-use values. In addition, in the summary of studies it is unclear how the dollar values for the WTP estimate were adjusted for inflation and put into a comparable year, until the reader gets to the table at the very end of the section. 27 The social welfare section lacks robust quantitative analysis; therefore, the analysis lacks scientific rigor for all scenarios. It is overwhelmingly qualitative in nature; the authors defend this putative necessity by stating: Due to the complexity of fishery management, it is not possible to predict changes in fishery management that may result from changes in fish abundance. This lack of quantitative data makes is difficult to compare scenarios and hard to determine the magnitude of impact(s) on social welfare. The Final EIS should include an assessment using the current fishery management schema as the baseline and quantitatively estimate changes in management structures, actions and allocations according to predicted changes in species abundances. This approach may require some assumptions; however, it would make quantitative comparisons of the alternatives possible and the necessary assumptions could be clearly defined, presented, and disclosed, including a discussion of uncertainty related to future fishery management.	The EIS acknowledges in Section 3.15.2.2 that various definitions of passive use values exist, and that this document relies on the definitions consistent with the referenced source studies in this section, as well as the Northwest Power and Conservation Council and NMFS. Based on these definitions, for example, catch and release fisheries are a non-consumptive use value, whereas keeping fish to eat would be a consumptive use value. Passive use values include the option to use the resource in the future ("option value") and thus are referred to as "passive use" instead of "non-use," although these terms are often used synonymously. Additionally, passive use/non-use values are described as a component of total economic value in this Section. The commenter is correct that the EIS does not include a quantitative analysis of the effects of the alternatives on fisheries. Consistent with NEPA analysis framework, the beneficial and adverse effects in the EIS are expressed as a variety of qualitative and quantitative environmental and economic metrics. The fisheries analysis references the effects of the alternatives on fish, as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis.
6692	37	nina.englander@doj.state.or.us	Oregon Department of Justice	Failure to Utilize High Quality Information and Accurate Scientific Analysis The water quantity/quality dataset for the PA provided to the fish modelers characterized variation on a daily average time step (CSS-78). The Juvenile Fish Passage Spill Operations measure in the PA, based on the Regional 2020 Flexible Spill Agreement operation requires data analysis on an hourly time step given operations change within day (i.e., 16-hours enhanced spill/8-hours power-focused spill). Because fish at dams begin to sound at dusk, they are more vulnerable to increased powerhouse encounter rates during nighttime hours than during daytime hours. This behavior cannot be modeled where input data do not capture diel variation in water quantity/quality parameters. Therefore, the fish modeling results are almost certainly overestimating the actual survival benefit of the PA (CSS Memo CRSO-77; Chapter 2 of the CSS 2019 Annual Report). The PA, as currently constructed, will not be able to provide adequate fish survival benefits particularly in light of pressures on survival from future climate change. Although the CSS modeling predicts a slight improvement in SARs under the PA, compared to the NAA, predicted mean rates were still far less than the 4% regional benchmark necessary for healthy and harvestable populations. Further, SARs at the lower end of all simulations (i.e., 25th percentile) for the PA was less than 2%; below the level necessary (2% SAR) to achieve population replacement and avoid generational decreases in abundance. These values at the lower end of predictions will become increasingly more likely with future climate change as conditions in both freshwater and the ocean vary more dramatically. The only alternative analyzed as part of the CRSO EIS capable of SARs that meet these regional goals to rebuild populations (2% SARs) and provide for recovery to healthy and harvestable populations (Average 4% SARs) is MO3 the alternative including breach. Yet, language in the PA dismisses the breach measures as viable components of a PA as they would likely, in the Action Agencies' estimation, preclude meeting many objectives of the purpose and need. The argument focuses heavily on deleterious impacts to flood risk management (FRM), water supply/irrigation, hydroelectric power generation, navigation and recreation and seems to imply that these impacts cannot be mitigated. In addition, and as noted above, the PA fails to acknowledge that breach measures are the only mitigation action that would likely lead to recovery of imperiled salmon and steelhead stocks. The document seems to 28 point to uncertainty in modelling of benefits to fish as a rationale to discount output, yet one conclusion remains consistent among the different approaches (i.e., CSS vs NWFSC fish modeling results); breach appears to be the one path that could precipitate recovery of listed	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives, including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. In its analysis of effects, the CRSO EIS used high-quality data and best science, including models and studies published in peer review science journals. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% as a result of the Preferred Alternative, increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the CRSO EIS. The Preferred Alternative will make a substantial contribution towards recovery targets. Regarding biases due to hourly vs. daily averages: In practice, model estimates may not underestimate powerhouse passage (or overestimate survival) due to day vs. night passage differences because limitations on nighttime spill reductions are already in place through the adaptive management process and lessons learned from the 2019 flexible spill operation. These adjustments in the amount of night-time spill were informed by state, Tribal, and Federal biologists with expertise in dam operations and their effects to fish passage. These examples of adaptive management will continue during post-ROD operations.
6692	38	nina.englander@doj.state.or.us	Oregon Department of Justice	Appendix R: The Process for Future Adaptive Implementation of the Fish Spill Operation Taken as a whole the description of the process for adaptive management simply implies the operations under the PA will change through time, starting in year 2 of 25. There is no actual information which allows the reader to discern how operations will change, and consequently, if operations will change for the better or worse for fish survival as compared to the first year of operation in PA (e.g., heavier focus on power generation). Further, specific language in Appendix R suggests future (i.e., beyond year two) implementation of a block spill experimental design or virtually any operational or structural adjustments to the PA deemed opportunities, regardless of whether those adjustments are detrimental to fish.	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component, of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team. The co-lead agencies do not feel that the short-term nature of this operation is an accurate interpretation of the Preferred Alternative. If no adaptive management needs are identified, the operation would continue through the duration of the ESA consultation period. The co-lead agencies will provide additional clarifying text in Appendix R to make these points more clearly.
6692	39	nina.englander@doj.state.or.us	Oregon Department of Justice	Failure to Accurately Disclose Likely Environmental Impacts for Specific PA Measures All but two of the Structural Measures in the PA either are measures retained from the NAA or are new measures developed to benefit lamprey (some of which are likely to constrain survival of salmon and steelhead). The only structural measures included in the PA that were developed to mitigate for reductions in salmonid survival are the Lower Granite Trap Modifications and the Bonneville Ladder Serpentine Weir Modifications. Both of these measures have been reduced in scope to only include trap gate modifications which will likely reduce anticipated benefits to less than measurable levels. Taken as whole, the Structural Measures in the PA will have an overall adverse impact on salmonid survival as compared to those in the No Action Alternative. Conversely, all of the Operational Measures in the PA are different from those proposed in the NAA except one: the Fall Operational Flexibility for Hydropower at Grand Coulee. Of the sixteen new Operational Measures, fifteen are likely to be harmful to salmonid survival either directly or by shifting risk of available water for spring flow from power generation or irrigation onto flow availability for fish. Only one Operational Measure, the Juvenile Fish Passage Spill Operation, is likely to benefit survival of salmonids as compared to the NAA. As noted, only one Operational Measure-Fall Operational Flexibility for Hydropower at Grand Coulee-is likely to be neutral to salmonid survival. Taken as a whole, the fourteen new Operational Measures are likely to be harmful to salmonids, functionally eroding the potential benefits of the Juvenile Fish Passage Spill Operation. Generally, any measures in the PA to promote salmon and steelhead survival would be ameliorated by actions to support other objectives; Concerns on measures specific to the PA These two PA measures showed promise for anadromous fish benefits early in the Draft EIS process but were narrowed in scope during development of the PA that any potential would be negligible and not likely measurable in magnitude: 29 1) Lower Granite Trap Modifications measure - The measure has been reduced in scope to include modifications to just the trap gate which may have also reduced the potential benefits to adult salmonid survival; 2) Bonneville Ladder Serpentine Weir Modifications measure - The measure has been reduced in scope to include modifications to just the trap gate which may have also reduced the potential benefits to adult salmonid survival as compared to its scope in MO1 and MO3; These seventeen PA measures are described as beneficial or neutral to fish survival in the Draft EIS but are actually harmful to anadromous salmonids if they were implemented: 1) Ice Harbor Project Turbines 1 to 3 Replacement and Generator Rewind measure- Even if the direct mortality of high-capacity turbines is shown to be no higher than that of the existing turbines, the increased turbine flow will lead to increase powerhouse passage of the run-at-large. This effect, compounded over multiple dams, will have a net negative impact on the smolt-to-adult returns. If the increased powerhouse flows are not included in the modeled datasets provided to the fish modelers, the increase in powerhouse passage will not have been reflected in the PA modeling fish analyses. This failure to accurately disclose impacts results in an overly optimistic picture of benefits to fish under the Preferred Alternative; 2) McNary Project Turbine Replacement measure- Even if the direct mortality of highcapacity turbines is shown to be no higher than that of the existing turbines, the increased turbine flow will lead to increase powerhouse passage of the run-at-large. This effect, compounded over multiple dams, will have a net negative impact on the smolt-to-adult returns. If the increased powerhouse flows are not included in the modeled datasets provided to the fish modelers, the increase in powerhouse passage will not have been reflected in the PA modeling fish analyses. Ultimately this results in a Draft EIS description of a measure beneficial to fish survival that in reality will be a measure that is detrimental to fish survival; 3) Improved Fish Passage Turbines at John Day Dam measure- Even if the direct mortality of high-capacity turbines is shown to be no higher than that of the existing turbines, the increased turbine flow will lead to increase powerhouse passage of the run-at-large. This effect, compounded over multiple dams, will have a net negative impact on the smolt-toadult returns. If the increased powerhouse	The commenter is correct in that many actions currently underway to improve the conservation and survival of anadromous fish in the CRS are being carried into the Preferred Alternative (PA). It is also correct that not many new structural changes are included in the PA. That is because the overhaul of the CRS for fish passage, which has been undertaken over the past few decades, is nearing completion. While the co-lead agencies did consider additional passage structures, only a few were carried forward into the PA. Instead, the PA includes increasing spill for juvenile fish as the primary means of improving survival for salmon and steelhead migrating through the system. This is no small change: in order to implement it the States of Washington and Oregon had to change their water quality standards. The CSS model predicts an overall improvement in SARs for Snake River salmon and steelhead as a result of the Preferred alternative, averaging greater than 2% for both salmon and steelhead. In addition, the Preferred Alternative has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The co-lead agencies do not agree that powerhouse flows were incorrectly captured in the EIS analysis. Turbine flows were accurately represented in the No Action Alternative for Ice Harbor and McNary turbines as well as for John Day in the Preferred Alternative. The co-lead agencies would remove screens in front of IFP turbines only after testing to ensure passage conditions would not erode overall dam survival. PITPH would not change with screens in or out. Operations above 1% peak turbine efficiency in order to manage TDG, implement the use of contingency reserves, and carry balancing reserves are expected to be utilized on a basis that will have negligible effects on salmon and steelhead. The co-lead agencies have provided estimates of frequency and duration of these operations and do not expect them to have a measurable impact. These operations were also included in the co-lead agencies proposed action to NMFS and USFWS for further review and potential refinement. While different from the No Action Alternative, the increased forebay range flexibility measure is the same operation as described in the 2019-2021 Spill Operation Agreement and consulted upon in the 2019 NMFS CRS BiOp. This operation is not expected to have any biologically significant effect on travel time or survival. The early start of transport measure is intended to allow for early transportation to continue to monitor and assess the efficacy of transportation compared to in-river migration. If migration timing shifts earlier, this will be an important operation to consider. The actual start of spring transportation will continue to be coordinated with regional salmon and steelhead experts through the Technical Management Team. The co-lead agencies will implement the zero generation operation in a manner that has negligible effects to any salmon or steelhead present in the river. Nighttime operations will end prior to daylight hours and allow attraction flow to fish ladders to aid passage for fish that are attempting to pass the projects. Daytime zero generation operations will not be implemented until mid-December when juvenile and adult migration has largely ceased. These effects have been qualitatively assessed by the co-lead agencies and will also be reviewed by NMFS and USFWS during the development of their respective Biological Opinions. Avian predation, particularly of steelhead, continues to be an area of emphasis. The modified operation of the John Day reservoir has been proposed and supported by many regional salmon and steelhead experts. Contrary to the characterization in this comment, the full pool operation at the John Day project would only be implemented outside of the fish passage spill season (i.e. full pool operations would not occur in July and August).The temporary extension of Performance Standard spill is only anticipated for use in the event of unanticipated negative impacts of the 125% flexible spill operation included in the Preferred Alternative. This action would be used to alleviate known harm and would therefore be a benefit in the instances when used. Structural improvement at Little Goose are intended to improve known issues. Additional structural modifications would be proposed, assessed, and implemented if warranted and found effective through existing Regional Forum processes such as the Fish Facilities Design Review Workgroup (FFDRWG).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				flows are not included in the modeled datasets provided to the fish modelers, the increase in powerhouse passage will not have been reflected in the PA modeling fish analyses. Ultimately this results in a Draft EIS description of a measure beneficial to fish survival that in reality will be a measure that is detrimental to fish survival; 4) Fewer Fish Screens measure - Fish screens are in place to shift salmonid power house encounters toward bypass systems and away from turbines to increase survival. Assertions that "fish friendly turbines" will markedly reduce direct mortality is dubious, because even assuming a marginal reduction in mortality, removing screens promotes 30 passage through turbines; so, on average, the mortality burden will necessarily be greater than if screens were in place; 5) Sliding Scale at Libby and Hungry Horse measure - Storage Project draft limits/targets are set based on irrigation supply draft limits and/or FRM curves and targets. Any measure that allows for increased draft prior to spring refill or increased storage for irrigation will increase the likelihood that the volume of water that would have been available for spring flow augmentation is instead redirected to achieve refill targets or irrigation supply targets instead. This effectively prioritizes power production and/or irrigation over fish survival; 6) Modified Draft at Libby measure - Storage Project draft limits/targets are set based on irrigation supply draft limits and/or FRM curves and targets. Any measure that allows for increased draft prior to spring refill or increased storage for irrigation will increase the likelihood that the volume of water that would have been available for spring flow augmentation is instead redirected to achieve refill targets or irrigation supply targets instead. This effectively prioritizes power production and/or irrigation over fish survival. 7) Planned Draft Rate at Grand Coulee measure - Storage Project draft limits/targets are set based on irrigation supply draft limits and/or FRM curves and targets. Any measure that allows for increased draft prior to spring refill or increased storage for irrigation will increase the likelihood that the volume of water that would have been available for spring flow augmentation is instead redirected to achieve refill targets or irrigation supply targets instead. This effectively prioritizes power production and/or irrigation over fish survival; 8) Update System FRM Calculation at Grand Coulee measure - Storage Project draft limits/targets are set based on irrigation supply draft limits and/or FRM curves and targets. Any measure that allows for increased draft prior to spring refill or increased storage for irrigation will increase the likelihood that the volume of water that would have been available for spring flow augmentation is instead redirected to achieve refill targets or irrigation supply targets instead. This effectively prioritizes power production and/or irrigation over fish survival; 9) Slightly Deeper Draft for Hydropower measure - Storage Project draft limits/targets are set based on irrigation supply draft limits and/or FRM curves and targets. Any measure that allows for increased draft prior to spring refill or increased storage for irrigation will increase the likelihood that the volume of water that would have been available for spring flow augmentation is instead redirected to achieve refill targets or irrigation supply targets instead. This effectively prioritizes power production and/or irrigation over fish survival; 10)Contingency Reserves Within Juvenile Fish Passage Spill measure - This measure simply transfers the risk from a need for a contingency operational change from power generation onto fish survival. When contingency reserves are employed, fish survival will be diminished. Incorporation of this measure does not support the purpose and need of action to address improving the survival and recovery of species; 11)Above 1% Turbine Operations measure- This measure would increase the proportion of flow going through the powerhouse as opposed to over the spillway when implemented. Salmonid survival decreases as the proportion of flow increases going through 31 powerhouses as opposed to over the spillway. Incorporation of this measure does not support purpose and need of action to address improving the survival and recovery of species; 12)Increased Forebay Range Flexibility measure - This measure will increase the average forebay elevation in reservoirs during the salmonid outmigration season which will result in greater travel times and decrease salmonid survival; 13)Start Early Transport measure - Smolt-to-Adult return rates (SARs) are typically better for salmonids that migrate in the river as compared to those that are transported, particularly earlier in the spill season. This will likely decrease salmon and steelhead SARs; 14)Zero Generation Operations measure - this measure will effectively increase ponding during fall/winter periods. Although there will be few juvenile salmonids outmigrating during this period, there are kelt and adult overshoot steelhead that will need to move downstream preferably via spill as opposed to through turbines; 15)Predator Disruption Operations measure - Similar to the Corps previous avian predation management plans, this measure is highly unlikely to be effective at decreasing predation rates by avian predators on juvenile salmonids. The avian predators of the Columbia River have proven to be extremely flexible in moving nesting locations in response to previous Corps management actions. At the same time increasing the forebay elevations during spring salmonid outmigration periods will not likely be effective at reducing avian predation rates and will increase juvenile salmonid travel time and decrease survival of outmigration salmonids through the John Day reservoir; 16)John Day Full Pool measure - operating John Day pool at full elevation will create a larger reservoir surface area which will decrease juvenile salmonid survival during the fish passage season and increase the collection and absorption of solar radiation over the summer and early fall portions of the year. This will likely increase water temperatures during periods (July, August, and September) when temperatures already exceed state and tribal water quality standards and lead to decreased adult salmonid survival and possibly the incidence of severe adult fish kills such as those that occurred in 2015; 17)The Temporary Extension of Performance Standard Spill Operations mitigation measure will negate any benefits to salmonid survival resulting from the Juvenile Fish Passage Spill Operations measure; This PA measure will only prolong unintended consequences to anadromous fish if repaired to status quo: 1) Maintenance improvements to the Little Goose jetty and retaining wall mitigation measure - as currently described, this measure would simply repair/rebuild the jetty and retaining wall to preexisting condition. The Little Goose tailwater configuration is the most problematic project from the perspective of potential adult delay and/or juvenile egress of all the projects under consideration as part of the CRSO EIS, particularly during high spill conditions. Juvenile fish passage spill is annually curtailed at this project due to potential unintended biological consequences - perceived adult delay. Alternatively, this mitigation measure should first evaluate what tailrace configurational 32 changes need to occur to alleviate the unintended biological consequences and rebuild tailrace structural features in such a way as to provide meaningful mitigation rather than just rebuilding to the known problematic status quo configuration.	
6694	1	ander690@wwu.edu	N/A	My main concern is in regards to how this report addresses the plans to comply with the Endangered Species Act. As it stands, this report shows the Columbia River Systems Operations preferred course of action is to maintain its dangerous status quo in regards to the endangered fish populations of the Snake Dams and effectively ignore the consideration of dam breaching. I understand that dam breaching was one of the actions considered in MO3, but due to the fact that this option is not preferred, and because economic cost was more greatly considered than ecological cost, it is clear to see that MO3 actions will not be implemented if considerable pressure is not put on your organization. Without dam breaching, the perilous state that Chinook and other fish species are currently existing in the Lower Snake River will be extended, and almost guarantee the eventual extinction of this species that you are required to restore to comply with the mandates of the Endangered Species Act and the Northwest Power Act. I greatly question the listed preferred action which includes to maintain these dams that have been demonstrated to cause the decline of endangered fish species and maintain these fish at a fraction of their historic abundance. This is unacceptable when you consider that this is in complete violation of the Endangered Species Act. Additionally, I believe it to be wildly irresponsible that not one peer reviewed article was cited in the entire DEIS report. There is clear, scientifically backed evidence that shows that 1) the current, costly efforts in salmon conservation are not working to increase salmon populations and 2) the only action that has been shown to work in regards to greatly restoring endangered fish species hurt by dams has been dam breaching.	There are many factors that effect salmonid populations that are outside the authority of the co-lead agencies. Both human-caused and natural factors that are outside the responsibility and control of the co-lead federal agencies, also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple legal responsibilities, including compliance with Section 7 of the Endangered Species Act. Under Section 7(a)(2) of the ESA, the co-lead agencies must insure that any action authorized, funded, or carried out is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Section 3.5 provides a summary of the fish analysis for the No Action Alternative and four of the multiple objective alternatives. Chapter 7 provides a summary of the fish analysis for the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets. Chapter 8 demonstrates the agencies compliance with applicable laws, including NEPA and the ESA. Finally, Chapter 11 includes all of the references relied on in the EIS, including peer-reviewed articles.
6694	2	ander690@wwu.edu	N/A	Five years ago, the 106 foot San Clemente Dam located on this river was torn down due to concerns over the endangered steelhead trout that are indigenous to this area. Before the dam was removed, there were many conservation efforts similar to the ones occurring on the Columbia River, and just like the Columbia River, none of them were working to restore steelhead. Now, just five years later, over a hundred endangered trout have been found past the dam removal site where zero existed before, and the number is projected to keep growing.	The commenter is correct regarding success in restoration of spawning habitat and reintroduction into blocked areas following dam removal such as on the Elwha or San Clemente Rivers. However, these examples do not necessarily have relevance to the lower Snake River Dams. Using some prominent examples in the Pacific Northwest, the Elwha and Condit dams had no passage, and provided few economic benefits. The Draft EIS analysis predicts short term adverse effects including high sediment and low oxygen concentrations that will be harmful to fish as a result of dam breach. However, the Draft EIS also found that in the longer term, the alternative that includes the measure to breach the lower Snake River dams has the greatest predicted benefit for Snake River salmon and steelhead compared to the other alternatives. The EIS set forth eight objectives which, in tandem with the purpose and need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the alternative that includes the measure to breach the lower Snake River dams. However, the Preferred Alternative also meets the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. The alternative that includes the measure to breach the lower Snake River dams, by contrast, has significant regional economic impacts and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend dam breaching because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6697	1	cknowles@biologicaldiversity.org	Center for Biological Diversity	Scientists from the Fish Passage Center have stated that breaching all four of these dams would result in roughly one million adult Chinook salmon returning to the mouth of the Columbia River, providing significant relief for endangered Southern Resident orcas. As you know Chinook salmon are the orcas' primary food source from central California to the Salish Sea, and the Columbia Basin supports salmon runs that the orcas have relied on for centuries.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and

					WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The scientists from the Fish Passage Center (FPC) models predicted that breaching the four lower Snake River dams would result in an increase in about 100,000 adult Chinook salmon returning to the mouth of the Columbia River (see Section 3.5). The FPC has indicated that an alternative not analyzed in the CRSO, which includes breaching the four lower Snake River dams, along with increasing spill at the lower Columbia River projects to the 125% gas cap would result in about one million fish returns. This alternative was not analyzed in the CRSO EIS. Improving ESA-listed juvenile and adult anadromous salmonid conditions were two of the eight multiple objectives of the CRSO EIS. The agencies disagree, however, that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative.
6705	1	aloise.ca@gmail.com	N/A	First, there are 72 Southern Resident Orcas left. They are starving to death as the four lower Snake River dams cut off salmon runs. Second, every year some 8 millions salmon are killed by these dams. These two species are going extinct even with all the money spent on hatcheries and fish ladders have not solved the problem so that now the Salmon returns to the Snake River system are only 5% of their historical numbers. There is no recovery from extinction and if we don't address this now, all of the North American West Coast will be affected by the extinctions of Salmon and the Southern Residents. This scenario is not ok! By failing to act, You are violating endangered species act.	Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed anadromous fish species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). According to NOAA and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8 in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8).
6705	2	aloise.ca@gmail.com	N/A	So, we are, now, in 2020, Salmon population has further declined. For example, Snake River sockeye salmon were listed as endangered in November 1991, and their listing was reaffirmed in June 2005. This list, from 2005, includes Five anadromous salmon populations and three anadromous steelhead trout populations present in the LSRP. And nothing, in your actual or past EIS, indicate the repercussions on the greater environment of the ocean, including Resident Southern Killer Whales, who are directly impacted by, has they were placed on the endangered species list in 2005.	Chapter 6 of the EIS includes RFFA 7, Fishery Management, addresses Salmon Fishery Management Plans – commercial fisheries plans prepared by the Pacific Fishery Management Council (PFMC), which are implemented and enforced by NMFS in Federal waters (e.g., 300 miles offshore). The "greater ocean environment" beyond the proximity covered in these plans is out of the scope of this EIS. Currently, PFMC has established a Southern Resident Killer Whale Workgroup to reassess the effects of Federal ocean salmon fisheries on Southern Resident killer whales and to potentially recommend conservation measures or management that better limit fisheries effects on Chinook salmon in Federal waters. Chapters 6 and also discusses the cumulative effects to Anadromous Fish, including Snake River sockeye is discussed in Sections 6.3.1.4 and 7.9.7.
6705	3	aloise.ca@gmail.com	N/A	EPA documents showed, the Four Lower River Snake Dams have been a problem since the beginning, by failures on respecting the Endangered Species Act, the Fish and Wildlife Coordination Act of 1958 and the Water Resources Development Act of 1976.	The co-lead agencies demonstrate compliance with applicable laws in Chapter 8. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. As described in Chapter 7 of the FEIS, the preferred alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective Alternative 3 (MO3), which includes breaching the four lower Snake River dams. However, the preferred alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply and greenhouse gas emissions, while minimizing adverse impacts to communities and the economy. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Section 3.5 provides a summary of the fish analysis for the No Action Alternative and four of the multiple objective alternatives. Chapter 7 provides a summary of the fish analysis for the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. To comply with the Fish and Wildlife Coordination Act (FWCA), the co-lead agencies have coordinated and responded to three FWCA Reports: a 1972 report for construction of the lower Snake River Dams; in 1995 report for the Columbia River System Operation Review project, and a 2020 report for this current CRSO EIS (see Appendix U). In 1975, Lower Snake River Fish and Wildlife Compensation Plan (LSRCP) was developed using the 1972 FWCA Report as the basis, and authorized by Congress in the the Water Resources Development Act of 1976.

6714	1		The Legislative Committee of the Oregon Chapter of the American Fisheries Society	Climate Change Effects and Implications. The Columbia River System Operations Draft Environmental Impact Statement (CRSODEIS) Multiple Objective 3 (MO3) evaluates the removal of the Snake River dams. While the CRSODEIS states this alternative [s]howed the highest predicted potential smolt-to-adult returns (SARs) for Snake River salmon and steelhead among the alternatives, it is rejected based in part citing [i]ncreases in juvenile salmon and steelhead survival, decreases in travel time, and reductions in powerhouse encounters in MO3 could be reduced or offset by the effects of climate change. The CRSODEIS states this is because Breaching the lower Snake River dams would require replacement of lost power generation and flexible capacity. Lost power generation could be replaced by gas or renewable sources. Loss of navigation would result in an increase in truck and/or train transport. The CRSODEIS contention that [l]ost power generation could be replaced by gas or renewable sources. Loss of navigation would result in an increase in truck and/or train transport relies heavily on the status quo. The analysis does not consider potential savings from conservation measures such as energy efficient buildings or increasing home solar units. The CRSODEIS assumes the extra trucks and train engines will use traditional diesel fuel rather than biodiesel. For consistency in assessment, the Preferred Alternative as well as MO3 must respond to the evaluation criterion: Minimize Greenhouse Gas Emissions from Power Production in the Northwest by Generating Carbon Free Power Through a Combination of Hydropower and Integration of Other Renewables. In the current CRSODEIS, the Preferred Alternative is not fully evaluated on this criterion. The ORAFS considers climate change to be a dire threat to native fishes of the Pacific Northwest. Climate change and its associated ocean acidification from increased levels of CO2 in the atmosphere are also serious threats to marine shellfish and finfish including migratory salmon, steelhead, smelt, lamprey and sturgeon that depend on the ocean for part of their lives. Climate change, ocean acidification, and alternative means of generating and conserving electricity to reduce greenhouse gas emissions are not as new to ORAFS as to many entities. The ORAFS has been addressing the climate change issue for over 30 years and in 1990 presented an Award of Merit to Sam Sadler of the Oregon Department of Energy for his leadership in compiling the Oregon Task Force on Global Warming: Report to the Governor and Legislature. Part One: Possible Impacts on Oregon from Global Warming. Part Two: State Agency Recommendations and Proposed Actions. June 1990. This involvement has made ORAFS very familiar with alternative ways that have been implemented to generate and conserve electricity in the Pacific Northwest and with new alternatives being developed, such as wave energy buoys off the Oregon Coast. The CRSODEIS contends there may be an increase in greenhouse gasses from the removal of the Snake River dams. However, much of the presumed increase is speculative. In contrast, benefits to Pacific salmon, steelhead, and Pacific lamprey, as well as other native fishes in the Columbia River basin will be direct, immediate, and undeniable. The CRSODEIS needs to respond to the question of how greenhouse gasses from removing the Snake River dams can be compared with improved fish passage, water quality, spawning habitat, as well as the [m]ajor long-term beneficial effects to wetlands, floodplains, fish, wildlife, and vegetation in the Lower Snake River. (CRSODEIS).	The decline of salmon populations is complex and recovery of those species will take collaboration between various agencies including NOAA and the Tribes. The co-lead agencies acknowledge that the ocean environment is a contributor to the decline in salmon populations that is beyond the scope of the CRSO EIS. While none of the alternatives would affect ocean conditions, we recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of this environment in the return of adult salmon and steelhead (Peterson et al. 2019). As such two of the models used in these analyses, NMFS Lifecycle and CSS models, use metrics of ocean productivity to predict adult returns. The carbon-free attributes of the Federal hydropower system are described in the Air Quality Section of the Draft EIS (Section 3.8). The analysis includes the effects to GHG emissions resulting from changes in hydropower generation for each alternative, including breaching the Lower Snake River dams in MO3. Overall the conclusion in the Draft EIS is that MO3 would be beneficial to anadromous fish for a number of reasons, but other objectives must also be considered in the selection of a Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6714	2		The Legislative Committee of the Oregon Chapter of the American Fisheries Society	Thermal Effects. Salmonid migrations are delayed by excessive temperatures, resulting in increased pre-spawn mortality of adults (Sherwood 2015)5 as well as increased morbidity and decreased production of juveniles and smolts (Hughes & Davis 1996)6. As indicated in the decision of U.S. Ninth Circuit Court of Appeals in Columbia Riverkeeper vs. Wheeler (2019)7, the Washington Department of Ecology had failed to issue temperature TMDLs (total maximum daily loads) for the Lower Snake River. USEPA (2020)8 listed a 20 C 1-day maximum for the Lower Snake River. Oregon Department of Environmental Quality 7-day average maximum temperature criteria for salmonid spawning, rearing, and migrating salmon are 13 C, 18 C, and 18 C, respectively (DEQ 2008)9. These criteria indicate that the Lower Snake River (as well as most of the Columbia River in the USA) is in violation of existing Oregon DEQ temperature criteria throughout most of its length (USEPA 2018)10. Those excessive temperatures are largely driven by the dam/reservoir projects because the reservoirs large surface areas and slower flows result in warmer water (USEPA 2018). Temperatures are further increased by warm tributary waters, irrigated agriculture return flows, and city and industrial point-source discharges. Continued climate change is expected to further warm the water and decrease the flows (USEPA 2018). How the breaching of the Lower Snake River dams would reduce the primary source of warming in that reach must be addressed in the CRSODEIS. Thermal issues in the Columbia and Snake rivers are exacerbated by abnormally warm temperatures resulting from climate change. For example, in 2015, a combination of a heat wave, drought, and malfunction in temperature monitoring stations at Dworshak Dam lead to decreased flow releases in the Columbia River during peak upstream migration of Snake River Sockeye Salmon. As a result, Columbia River temperatures at some stations were reported in excess of 25 C (NOAA)11 and NOAA estimates that only 8% of the returning Sockeye Salmon survived passage between Bonneville Dam and Lower Granite Dam, compared to a 5-year average survival rate of 64%. In addition, Nelson (2019)12 estimates that migration rate slowed significantly as a result of elevated stream temperatures, with migrations taking an extra 10 days to complete. These low flow/high temperature events are predicted to be more common and extreme as the climate warms. Surviving these events requires a combination of (1) rapid migration not impeded by dams or reservoirs, and (2) cold-water refugia where fish can hold during migration.	Historically, water temperatures in the lower Snake River were warm (USGS 1960, 1961, 1964; Corps 2002a). Observed historic water temperatures show that average monthly water temperatures during July and August, in the 1950s, averaged 7 to 8 degrees Fahrenheit higher than today's conditions, while maximum daily differences were 10 to 12 degrees Fahrenheit higher. The differences observed in the lower Snake River today, as compared to historical conditions, are a result of the middle and upper Snake River reservoirs combined with the influence that Dworshak Dam operations. The EIS analysis shows that when breaching the four lower Snake River dams, nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges. The models showed minor changes in the Columbia River under MO3, indicating that the operations of the CRS dams have a limited ability to reduce temperatures in the lower Columbia River. Summer water temperatures exiting the Snake River are typically 1 to 3 degrees Fahrenheit warmer than the receiving Columbia River temperatures. Even though the cold water released from Dworshak during the summer is less than 50 degree Fahrenheit, the volume of water released is less than one tenth of the flow in the Columbia River. Since the distance between the confluence of the Snake and Columbia Rivers is about 180 miles downstream from Dworshak, the impact on water temperatures is negligible. Regionally high air and water temperatures result in water quality standard exceedances that are beyond the ability of the CRS to cool. Overall the conclusion in the Draft EIS is that MO3 would be beneficial to anadromous fish for a number of reasons, but other objectives must also be considered in the selection of a Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6714	3		The Legislative Committee of the Oregon Chapter of the American Fisheries Society	Habitat Connectivity. The critical role of connected rivers for the long-term persistence of native migratory fishes has been alluded to earlier in this letter. Hydroelectric facilities affect fish passage as well as daily and seasonal patterns of river flow and temperature (Poff et al. 1997)13. Whereas the focus of mitigation at dams often focuses on passage, generally for highly mobile fishes, the impacts on the overall pattern of river flow can affect the timing of life stage progression of native fishes (Waples et al. 2009)14. Migratory fishes are adapted to predictable patterns of discharge and temperature that cue transition between life stages. Water storage and non-ecologically driven river discharge patterns associated with anthropogenic needs for hydropower and municipal/agricultural water at best complicate, and at worst negate life stage completion for native fishes. Dam removal facilitates the return of natural flow regimes and seasonal patterns of available river flow that are critical for native fishes and floodplain ecosystems. Persistence of imperiled salmonids relies on access to habitat for juvenile, smolt and adult life stages. While passage improvement has reduced mortality through Columbia River dams, the alteration to the hydrograph and river habitats has not been effectively mediated through dam management actions. In fact, alterations in flow and temperature associated with hydroelectric dam construction has already dramatically altered the environment (Arismendi et al. 2012)15. How the Preferred Alternative and MO3 address the issue of altered flow regimes needs to be addressed in the CRSODEIS in order to evaluate the different alternatives with respect to fish life history completion.	Flow and temperature, and how these are affected by MO1, MO2, MO3 and MO4 relative to the No Action Alternative is analyzed in Chapter 3 and in Chapter 7 for the Preferred Alternative. Flow is also incorporated into the COMPASS model and the CSS and NMFS life cycle models for salmon and steelhead. Regarding MO3: The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
6714	4		The Legislative Committee of the Oregon Chapter of the American Fisheries Society	The Northwest Power and Conservation Councils Fish and Wildlife Plan, created in response to the Power Act, has spent 30 plus years and more than 17 billion dollars and has failed to reach its modest goal of just 5 million salmon returning to the Columbia River. The program is largely based on the status quo that employs hatcheries as a substitute for conservation (i.e., mitigation). The EIS must recognize the status quo has failed and that parity is now more important than ever. As the Independent Scientific Advisory Board stated [i]f the region is serious in its desire to restore wild Pacific salmon the status quo is not an option. (Williams et al. 1999)	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Similarly, the Northwest Power Act does not obligate the co-lead agencies to recover ESA-listed species or to ensure restoration of other fish and wildlife. Instead, the co-lead agencies fish and wildlife mitigation responsibilities under Northwest Power Act are more limited primarily, managing and operating FCRPS projects, which includes the CRS, to protect, mitigate, and enhance (as opposed to recover) fish and wildlife affected by such projects in a manner that provides equitable treatment with the projects other authorized purposes and consistent with the purposes of the Act and applicable laws. In addition, Bonneville has a specific responsibility to fund protection, mitigation, and enhancement of fish and wildlife to the extent affected by development and operation of FCRPS projects consistent with the Northwest Power and Conservation Councils (Council) fish and wildlife program, the Councils power plan, and the purposes of the Act, which includes assurance of an adequate, efficient, economical, and reliable power supply. Therefore, contrary to the comments broad assertion, the Northwest Power Act does not make Bonneville responsible for funding the regional effort to recover wild salmon and steelhead. Moreover, the comments suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
6714	5		The Legislative Committee of the Oregon Chapter of the American Fisheries Society	The new Environmental Impact Statement (EIS) for the operation of the Columbia River power system directly affects sustainable management of fishes in the Columbia River basin and does not include a comprehensive discussion of several points. We summarize our three major areas of concern below. Opening statement. Recent archaeological research found a remarkable stability in salmon use by Native Americans over a period of 7,500 years in the Columbia basin (Campbell and Butler 2011)1. However, by 1870, Euro-Americans dominated the salmon fisheries and their management. In a relatively short 150 years, the Euro-American management of the Columbia Rivers two key resources–salmon and the water– brought the salmon to the brink of extinction. There are many causes for this, but most are subsumed under one overarching problem, which is clearly shown in the following paragraph from a statement signed by the United States Secretary of the Interior on March 6, 1947: It is, therefore, the conclusion of all concerned that the overall benefits to the Pacific Northwest from a thoroughgoing development of the Snake and Columbia are such that the present salmon run must be sacrificed. This means that the Departments efforts should be directed toward ameliorating the impact of this development upon the injured interests and not toward a vain attempt to hold still the hands of the clock (Gardner 1947) This statement clearly showed a dismissive attitude toward salmon. The salmon were relegated to a much lower priority than economic development in the Columbia basin. The result was catastrophic. The Northwest Power and Conservation Council estimates that, at a minimum, the number of salmon entering the Columbia River prior to economic development was approximately 10 million fish (Northwest Power Planning Council 1986)3. The recent average has been around 2 million salmon. So, the lower priority for salmon has created an approximate annual deficit of 8 million fish. Congress recognized that the higher priority given to economic	Chapters 5 (Section 5.2.1), Chapter 7, and Chapter 8 (Section 8.3.6) as well as the introduction (p. 16) describe the co-leads requirements to comply with the Power Act. Provisions of the Northwest Electric Power Planning and Conservation Act of 1980 (Northwest Power Act) (16 U.S.C. 839 et seq.) require Bonneville to balance multiple public duties and purposes: helping to ensure the Pacific Northwest has an adequate, efficient, economical, and reliable power supply; promoting energy conservation and the use of renewable resources; and, consistent with the program developed by the Northwest Power and Conservation Council (Council), protecting, enhancing, and mitigating fish and wildlife to the extent affected by the development and operation of the Federal Columbia River Power System (FCRPS), which includes the CRS. Bonneville complies with these provisions of the Northwest Power Act through the Fish and Wildlife Program and other actions. Under the Northwest Power Act, the co-lead agencies exercise their responsibilities of operating the CRS in a manner that provides equitable treatment for fish and wildlife and with the other purposes for which CRS facilities are operated and managed. In addition, the co-lead agencies consider in their decision making the Councils Fish and Wildlife Program and Mainstem Amendments to the fullest extent possible. In their management and operation of the CRS, the co-leads have fulfilled the fish and wildlife mitigation mandate in the Northwest Power Act, providing fish and wildlife equitable treatment with the other congressionally authorized purposes of the FCRPS (16 USC 839b(h)(11)(A)(i)). Since the 1990s, the Federal agencies have overhauled system operations and infrastructure, achieving juvenile dam passage survival that meets or exceeds performance standards of 96% and 93% for spring and summer migrants respectively, a marked improvement as compared to when Congress passed the Act. Travel time improved for yearling Chinook and juvenile steelhead through the system, even in low flow years such as 2015, 3 and total In-River survival has improved for migrating juvenile salmon and steelhead. Comparing two time periods reported in NOAAs reach study, (19972007 and 20082016), there has been a 10% survival increase for hatchery and wild sockeye salmon, a 2% increase in hatchery and wild Chinook (4% for wild), and a 25% survival increase for hatchery and wild steelhead (13% for wild). Bonneville's Fish and Wildlife (F&W) Program funds hundreds of projects each year to mitigate the impacts of the development and operation of the Federal hydropower system on fish and wildlife. Offsite protection and mitigation actions typically address impacts to fish and wildlife not caused directly by the CRS, but they are actions that can improve overall conditions for fish to help address uncertainty related to any residual adverse effects of the CRS. For example, F&W Program funding improves habitat in the mainstem as well as tributaries and the estuary, builds hatcheries and boosts hatchery fish production, evaluates the success of these efforts, and improves scientific knowledge through research.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				development relative to salmon was a mistake and tried to correct the error by enacting the Pacific Northwest Electric Power Planning and Conservation Act of 1980 (Power Act). One of the goals of the Power Act was to attempt to create parity between fish and electric power production in terms of river management (McConnaha et al. 2006)4. Now, the region is about to adopt a new EIS for the operation of the Columbia River power system. Will the EIS achieve the parity Congress intended between power (economic development) and the great Pacific salmon runs of the Columbia River system?	The comment further claims that there is no evidence in the EIS of the agencies adherence to the equitable treatment mandate of the Act. The equitable treatment provision of the Act directs the agencies management and operation of the Columbia River System provide equitable treatment for fish and wildlife with the other authorized purposes for which the system is managed, such as flood risk management, hydropower generation, irrigation, navigation, and recreation. See 16 U.S.C. 839b(h)(11)(A)(i). The co-lead agencies provide fish and wildlife with equitable treatment on a system-wide basis. See NW. Envtl. Def. Ctr. v. Bonneville Power Admin., 117 F.3d 1520, 1533-34 (9th Cir. 1997) (While each power marketing action that affects the system implicates the equitable treatment provisions, Bonneville may properly exercise its obligation by insuring equitable treatment for fish on a systemwide basis.); Confederated Tribes of the Umatilla Indian Reservation v. Bonneville Power Admin., 342 F.3d 924, 931 (9th Cir. 2003) (The equitable mandate of [the Northwest Power Act] does not require every Bonneville decision to treat fish and wildlife equitably. For example, Bonneville may make some decisions that place power above fish, so long as on the while, it treats fish on par with power.). Through this EIS process, the co-lead agencies have considered management and operation of the Columbia River System for its multiple authorized purposes. And, as noted above, CSS analysis of the Preferred Alternative predicts an increase in smolt-to-adult return rates as compared to the no action alternative. The co-lead agencies inclusion of alternatives MO3 and MO4 which are focused on benefiting fish, plus the incorporation of measures specifically designed for improved benefits to fish and wildlife, as balanced against other purposes, reflects equitable treatment of fish and wildlife consistent with the Northwest Power Act.
6718	1	N/A	N/A	The PA is a balanced approach that benefits the ESA-listed species while meeting the eight objectives developed by the co-lead agencies and minimizes adverse economic, environmental, and social impacts. Furthermore, it builds on the current Flexible Spill Agreement and supports adaptive management. However, we have concerns regarding utilizing Flexible Spill as the key component of the PA. Increasing spill levels to 125% Total Dissolved Gas (TDG) is an unprecedented action resulting in higher power costs.	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the biological models and will help to determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored, as will the effects to generating resources around the basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The EIS recognizes the concern voiced in the comment regarding increasing power rates. Under the Preferred Alternative, which includes juvenile fish passage spill operations contemplated under the 2019-2021 Spill Operation Agreement, the Bonneville's wholesale power rate pressure is 2.7 percent relative to the No Action Alternative. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement, and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control. See Draft EIS Section 3.7.3.1 at page 3-187.
6718	2	N/A	N/A	Further examination of the potential benefits and unintended consequences of higher spill levels must be conducted in the future as the 2019 operations of the Federal Columbia River Power System (FCRPS) at 120% TDG has shown minimal benefit to ESA-listed species. There must be scientific analyses conducted in the future that clearly shows the benefits of increased spill levels to this magnitude.	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects of free swimming fish; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
6718	3	N/A	N/A	Additionally, Clearwater supports strengthening and expanding measures to mitigate for avian predation in the Columbia Basin in the PA. Avian predation is a major source of mortality of ESA-listed species therefore, the Final EIS must include a thorough and detailed plan to address avian predators.	The Preferred Alternative includes measures to reduce avian predation on mitigate adverse effects to listed species from CRS operations. The Preferred Alternative includes a large suite of predation mitigation measures, some of which include maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. In addition, water management actions (the Predator Disruption Operations measure) in the John Day reservoir is expected to further reduce avian predation on migrating juvenile fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary. In addition, the co-lead agencies will continue to work closely with other entities in the region to mitigate impacts from pinniped and avian predators.
6722	1	N/A	N/A	As Idahos largest state-based conservation organization, we represent over 20,000 supporters, many of whom have a deep personal interest in anadromous and resident fish recovery, renewable energy, and rural Idaho communities. ICL represents members whose livelihoods depend on the return of abundant, harvestable populations of salmon and steelhead. Ensuring the restoration of these species is of paramount importance and directly impacts our members. Part of the purpose for this DEIS is to evaluate how to insure that the prospective management of the System is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of designated critical habitat, including evaluating mitigation measures to address impacts to listed species.1 ICL believes that recovery of endangered Snake River salmon and steelhead populations is inherently important, but also valuable for Idaho communities. We believe the action agencies should alter the Preferred Alternative to include the measures included in MO3. The DEIS and other research has shown that breaching of the lower Snake River dams leads to the highest probability of recovering endangered salmon and steelhead, and that there is no other path toward abundant, harvestable populations of these fish.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery as compared to the No Action. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.
6722	2	N/A	N/A	The Preferred Alternative will not recover endangered salmon and steelhead to ESA-delisting status, and certainly not to abundance. ICL is concerned that the Preferred Alternative does not address critical issues for Snake River spring/summer Chinook salmon and steelhead trout. It is clear that the DEIS process went awry from the start on this subject, when the objectives for CRS operations were limited to merely improving conditions for juvenile and adult migration through the system. The DEIS used no quantitative goals, beyond assessing whether a given alternative was better or worse than the No Action Alternative (NAA). Indeed, the Action Agencies have already been directed to not operate under the NAA, because those conditions put endangered fish populations in jeopardy of extinction. The Preferred Alternative does not improve that situation. In a time when regional wild salmon recovery goals are generally agreed upon as a Smolt to Adult Return (SAR) rate of 2 to 6% annually, averaging at least 4%, the Preferred Alternative falls well short. The model used to predict relative benefits to Snake River fish runs (CSS) showed that under the Preferred Alternative, Spring/Summer Chinook SAR would increase by 35% and steelhead SAR would increase by 28%.2 Taking average SARs from Snake River populations as a baseline for these predicted improvements, the results are still short of regional recovery standards. Across a 10-year period, SARs average 1.20% for wild Snake River Spring/Summer Chinook (LGR-BON, Juv. Migration 2006-2016) and 2.42% for wild Snake River steelhead (LGR-BON, Juv. Migration 2006-2016).3 The CSS results predict those metrics improving to 1.62% and 3.10%, respectively. If only recent returns are investigated, the results are even worse. For juvenile migration years 2014 to 2016, average SARs for the same populations are 0.44% for Spring/Summer Chinook and 1.07% for steelhead. Improvement, as predicted by CSS, would result in SARs of 0.60% and 1.37%, respectively. The LCM was not able to report results on steelhead (another 2 DEIS, page 33 3 Idaho Department of Fish and Game critical flaw in a well-funded and long-developing document), but its results for Chinook similarly do not bring that population within recovery standards. In addition, the Fish Passage Center (FPC), which developed the CSS and provided results to the Action Agencies for this report, is careful to note that model results for the Preferred Alternative are likely overestimates.4 Because of the nature of the flow data provided to FPC, the model cannot provide results at high enough resolution to factor in changes in spill during the day. Migrating fish are more likely to encounter the powerhouse during at night than during the day, and powerhouse encounters are a known contributor to mortality. Lower performance standard spill in evening or nighttime hours would thus increase powerhouse encounters (measured by the PITPH index). PITPH is an input for the CSS model, so a higher PITPH is very likely to lead to lower estimates for survival and SAR. The benefits claimed for fish under the Preferred Alternative, which already do not meet regional standards for recovery, could thus be vastly overstated. Analysis of the Preferred Alternative through CSS could be redone using flow and spill data at hourly resolution, which will factor in the timing of low spill operations and provide more accurate estimates of the impact to anadromous fish under the Preferred Alternative.	It should be noted that the 2-6% Smolt-to-Adult return (SAR) target referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the analysis of the Preferred Alternative, the co-lead agencies believe their actions will make a substantial contribution, but the Councils broad-sense recovery goals are beyond the scope of this EIS, which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Based on analysis by the CSS for this Preferred Alternative, SARs associated with population declines (SARs of less than 1%) have the potential to be reduced under the Preferred Alternative, and on average, SARs are expected to be above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. In practice, model estimates may not overestimate PITPH due to day vs. night passage differences because limitations on nighttime spill reductions are already in place through the adaptive management process and lessons learned from the 2019 flexible spill operation. These adjustments in the amount of nighttime spill were informed by state, Tribal, and Federal biologists with expertise in dam operations and their effects to fish passage. These examples of adaptive management will continue during implementation of the operations in the selected alternative.
6722	3	N/A	N/A	MO3 would most benefit ESA-listed species, but was not accepted as the Preferred Alternative. The DEIS includes an alternative under which much higher returns are predicted. MO3 presents improvements that would place Snake River SARs well within regional standards. Under MO3, the CSS model predicts that Snake River Spring/Summer Chinook SAR would increase by 170% and steelhead SAR would increase by 178%.5 Taking the 10-year Snake River SAR (LGR-LGR, Juv. Migration 2006-2016) averages (0.94% for wild Spring/Summer Chinook, 1.74% for wild steelhead), CSS predicts SARs of 2.54% for Chinook and 4.69% for steelhead under MO3. Again, if we factor in only recent years of returns (0.36% for wild Spring/Summer Chinook, 0.74% for wild steelhead), CSS predicts SARs of 0.98% for Chinook and 2.06% for steelhead. These predicted SARs are still mostly below the 4% average criterion, but it is clear from the analysis that the cornerstone of any plan to restore Snake River salmon and steelhead is breaching of the lower Snake River dams. Operational changes as proposed under the Preferred Alternative seem unable to achieve the same results.	The co-lead agencies disagree with this comment and instead reiterate the data in the CRSO Draft EIS appropriately represents the expected outcomes for salmon and steelhead associated with MO3. These impacts are framed appropriately with impacts to other authorized purposes. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. It should be noted that the 4% average SAR target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the Preferred Alternative analysis, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects.

					The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
6722	4	N/A	N/A	The DEIS uses different metrics to compare MO3 and the Preferred Alternative. Confusingly, the DEIS does not use the same SAR metrics for its comparisons of alternatives. For MO3, the CSS model predictions are based around SARs for juvenile fish that passed Lower Granite dam (LGR) and returned as adults to the same location. For the Preferred Alternative, CSS predictions are 4 Comparative Survival Study of PIT-tagged Spring/Summer/Fall Chinook, Summer Steelhead, and Sockeye, 2019 Annual Report, Chapter 2. Comparative Survival Study Oversight Committee and Fish Passage Center. http://www.fpc.org/documents/CSS/CRSO/CRSO-84.pdf 5 DEIS, page 25 instead based around LGR-BON SARs, which compare juvenile fish counted at Lower Granite with adult fish returning to Bonneville dam. These predictions for the Preferred Alternative exclude passage through the CRS as adults. This exclusion is significant because the Preferred Alternative could have negative impacts on adult fish migration through the system because of greater spill. When dams release more water to benefit juveniles, it can lead to fallback for migrating adults, or masking of the fish ladder.6 Each of these phenomena make upstream adult migration more difficult, with a clear effect on SAR. Thus, reported CSS predictions from Chapter 7 and the Executive Summary cannot truly be compared with CSS predictions reported for MO3. Predictions made for the Preferred Alternative are artificially inflated, as adults returning to Bonneville do not all return to Lower Granite, and this difference could be made even more significant by the spill regime included in the Preferred Alternative.	All of the SARs presented in the EIS were from Lower Granite Dam to Bonneville Dam. The Lower Granite Dam to Lower Granite Dam SARs presented in Chapter 3 for MO3 were a typo and should have read "Lower Granite to Bonneville Dam;" this has been corrected in the Final EIS. The intent is to have consistent comparisons between the multiple objective (MO) alternatives and the No Action Alternative consistent with NEPA.
6722	5	N/A	N/A	The DEIS does not adequately analyze future impacts of climate change on either a reservoir system retained under the PA or the riverine system created under MO3. Climate change is not properly addressed in the DEIS analysis of the multiple objective alternatives and the Preferred Alternative. While an analysis of climate change effects does appear in Chapter 4, these effects are never covered in comparing the alternatives and their relative impacts to fish and wildlife. Chapter 4 shows that climate change will have major effects on water quality and quantity in the Columbia River Basin. Higher air temperatures and an altered hydrograph could lead to increased water temperatures. This is a particular problem in the Snake River where parts of the system are already approaching or above lethal limits for steelhead, and fishway temperatures already cause fallback for Chinook, sockeye, and steelhead. This effect will increase as river temperatures rise7 and could cause moderate to severe changes in salmon and steelhead populations.8 It is clear that MO3 would cause large changes in the temperature regime of the lower Snake River, with much greater cooling at night, compared to operations under the NAA.9 Salmon suffer when water temperatures reach 68F or higher,10 as it currently does much of the time on the lower Snake River in the summer.11 With climate change, these temperatures, which already devastated Snake River sockeye in 201512, will continue to routinely ravage annual salmon and steelhead runs. Restoring the lower Snake River to its riverine form would allow the river to cool more quickly, providing cold water refugia for salmon and steelhead to migrate in as adults. The Preferred Alternative does little to mitigate the ongoing trend of warming water in the lower Snake River reservoirs. Predicted water temperatures under the PA are very similar to those under the NAA, 6 DEIS, page 1-101 7 DEIS, page 4-34 8 DEIS, page 4-33 9 DEIS, page 3-270, page 3-275 10 National Marine Fisheries Service, 2015 Adult Sockeye Salmon Passage Report, pp. 2022 (2016). 11 Fish Passage Center, Requested data summaries and actions regarding sockeye adult fish passage and water temperature issues in the Columbia and Snake rivers (Oct. 28, 2015). 12 Columbia and Snake sockeye decimated by 2015s warm rivers, The Idaho Statesman. https://www.idahostatesman.com/news/local/news-columns-blogs/letters-from-the-west/article71657737.html which are already dangerous for migrating adult salmon and steelhead. The DEIS predicts exceedances of water quality standards, even during average years. In average flow years, temperatures are expected to exceed 68F for much of the adult salmon migration season at each of the lower Snake River dams, and to exceed 72F at Ice Harbor dam.13 These predictions are based on historical operations, and do not reflect the expected effects of climate change. Hot summers with low flows, as occurred in 2015, will happen more and more frequently and it is imperative that salmon populations are given a migration corridor resilient to these effects. The DEIS acknowledges that for each of the alternatives, climate change will likely reduce the benefits and increase adverse effects to salmon and steelhead.14 However, no more specific analysis on any of the alternatives is completed, so it is impossible to ascertain the magnitude of effects (beneficial or adverse) of each alternative under a changing climate. Given this lack of depth, it is also not possible to conclude whether a given alternative will actually improve conditions for salmon and steelhead. Before any real conclusions can be made about whether an alternative improves conditions for salmon and steelhead, an analysis of each alternative under the expected impacts of climate change must be completed. Climate change is not a hypothetical scenario which might occur: it is a certainty, and its impacts need to be investigated as part of all alternatives.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). A system water quality model was developed to look at water temperature and TDG effects throughout the Columbia and Snake River system for this EIS. Breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges.
6722	6	N/A	N/A	The DEIS fails to rigorously explore and objectively evaluate alternatives to maintaining the electric system while meeting other multiple objectives. Here ICL comments on three aspects - the failure to use industry best practices to assess energy system options, the misrepresentation of the impact to system reliability, and the failure to properly include climate change in analysis of replacement generation portfolios. These are not the only flaws in the energy analysis portion of the DEIS. ICL incorporates by reference here the comments on this DEIS filed by the Northwest Energy Coalition. 1. The DEIS did not use well-known industry best practices to assess the need for and cost of replacement energy resources. The agencies state in the purpose and need to be met here that: This EIS will also allow the co-lead agencies and the region to evaluate the costs, benefits and tradeoffs of various alternatives to meet multiple objectives, including the ability to provide an adequate, efficient, economical, and reliable power supply that supports the integrated Columbia River Power System.15 All of the Multiple Objective Alternatives developed here would change the energy services provided by the CRS when compared to the No Action alternative. Thus, one of the most critical parts of this DEIS is captured in Appendix H, which analyzes the impact of the alternatives on the Columbia River System projects and transmission system.16 Here, the most important step in the analysis is to determine the Need for 13 DEIS, page 7-84 14 DEIS, page 4-37 to 4-38. 15 DEIS, page 16 16 DEIS, Appendix H Replacement Power Resources and Cost of Resources. This DEIS Replacement Power Analysis is irretrievably flawed due to the use of stale data, inadequate analytical tools, and misrepresenting the facts on the ground. Considering a range of alternatives to the proposed action is the heart of the environmental impact statement and the action agencies must rigorously explore and objectively evaluate all reasonable alternatives.17 This evaluation must be based on accurate scientific analysis, expert agency comments, and public scrutiny.18 And the agencies must insure the professional integrity, including scientific integrity, of the discussions and analyses in environmental impact statements.19 For decades, electric system operators in this region, and across the country, have used established industry best practices to perform this analysis through Integrated Resource Planning. For this DEIS the federal agencies did not use these established methodologies nor explain why the approach taken has scientific integrity. The agencies could have paired a legitimate Integrated Resource Plan with an Environmental Impact Statement. The Tennessee Valley Authority (TVA) published just such an analysis in 2019, which documents the hallmarks of a rigorous, scientific approach commonly used throughout the United States.20 The TVA IRP is highly instructive and relevant because this agency is essentially equivalent to the Bonneville Power Administration as a corporate agency of the United States with the mission of marketing power from federal resources to local power customers and providers. The most glaring difference between the TVA approach and the CRSO DEIS is the lack of alternatives the CRSO action agencies considered here. TVA evaluated 30 portfolios of resource options to determine the optimal portfolio to meet future needs.21 This is standard industry practice also used in the Northwest Region. PacifiCorp is a major electric system operator in the region with an IRP that considers 50 different portfolios to find the optimal mix of resources.22 Similarly the Idaho Power Company IRP considered 44 portfolios.23 By stark contrast, for the CRSO EIS the federal agencies considered just four alternatives to the No Action Alternative. Beyond the narrow range of alternatives, the CRSO EIS is further inadequate because each alternative was not an optimized collection of related measures, rather a hand selected, narrow choice of measures that does not properly incorporate how the CRS actually operates and the obvious technological and pricing trends in the industry. The Replacement Power analysis applied to these alternatives failed to follow industry standards and thus failed to take the requisite hard look required under NEPA. 17 40 C.F.R 1502.14 18 40 C.F.R. 1500.1(b) 19 40 C.F.R. 1502.24 20 TVA 2019 IRP available at: https://www.tva.com/Environment/Environmental-Stewardship/Integrated-Resource-Plan 21 TVA 2019 IRP at ES-6 22 PacifiCorp 2019 IRP, page 171, available at: https://www.pacificorp.com/content/dam/pcorp/documents/en/pacificorp/energy/integrated-resource-plan/2019_IRP_Volume_I.pdf 23 Idaho Power 2019 IRP at 99, available at: https://www.idahopower.com/energy-environment/energy/planning-and-electrical-projects/our-twenty-year-plan/ Industry best practice is for power system planners to use software tools to develop the optimal portfolio of options to meet electric system	The EIS uses multiple industry standard models and data to assess the effects of the changes in hydropower generation under each alternative. These included GENESYS, AURORA and GridView among others. The EIS describes the overall power models and methodology in the draft EIS in Section 3.7.3.1 Methodology and in additional detail in Appendices H, I and J. Regarding the consideration of climate change, the EIS evaluated the potential effects of climate change on hydropower generation, finding that uncertainty regarding future power generation under different potential climate change scenarios does not affect the overall conclusions of the alternatives. See Section 4.2.5, Chapter 7 and Appendix J Chapter 6 in the draft EIS for additional detail. The EIS uses the best available resource cost information from the Northwest Power and Conservation Council to estimate the potential range in costs of these replacement resources. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821 and Appendix H, Power and Transmission, at Section 2.2. The purpose of providing the range of replacement resource options is to present a reasonable range in potential costs. The basis for developing these portfolios may be found in Section 3.7.3.1, Methodology, and for Multiple Objective (MO) Alternative 3 specifically, Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS. The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council (Council) in its 7th Power Plan (7th Power Plan page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at page 3-821 and Appendix H, Power and Transmission, at Section 2.2. While the EIS specifically identified two portfolios, it evaluated all primary technologies from the 7th Power Plan to identify the most cost-effective resources at improving regional reliability. After identifying the most cost-effective resources, the EIS analyzed two resource portfolios to replace the hydropower generation of the lower Snake River dams, both of which maintain regional power system reliability. See Section 3.7.3.5, pages 3-904-910 in the draft EIS. One portfolio contains natural gas and the other was a renewable portfolio of solar, storage and demand response. In response to public comments, Appendix H, Section 2.2 in the Final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. The commenter suggests or questions why a competitive resource review, also known as an integrated resource plan (IRP), was not performed as part of the EIS analysis. An IRP is a resource planning tool that utilities use to plan for future resource builds and acquisitions to fulfill the utility's specific needs over a certain planning horizon, typically 20 years. Some utilities are required to conduct an IRP by their local or state utility commissions. Bonneville is not required to perform an IRP, but does perform resource planning to inform its decisions, including for this EIS. There are many different methods and tools that are used by utilities when performing an IRP. Furthermore, the output of an IRP is often driven by state energy policies, such as carbon emission requirements. Even if an IRP optimizes resource portfolios, the real costs of that portfolio are not known until a competitive request for proposal solicitation can be completed and evaluated. As explained in the draft EIS in Section 3.7.3.1, Base Case Methodology and Cost Sensitivities Analysis, the EIS analysis evaluates the power impacts of the MOs on regional power system reliability, as measured through loss of load probability (LOLP). The regional scope of the EIS is necessary because the impacts of the MOs on power system reliability and costs transcend individual utilities and states. Thus, for example, the EIS addresses the cost impacts of replacement resources for each MO regardless of whether Bonneville pays for the replacement resources. If Bonneville does not replace the lost capability caused by an MO, regional reliability would still be worse than the No Action Alternative and above the Council's 5 percent standard, leaving other regional utilities to acquire the necessary resources. The EIS addressed the regional nature of the costs and resources needed to maintain power system reliability under the MOs. Finally, the Councils RPM model does not include the necessary data to analyze alternatives to Columbia River System operations, maintenance and configuration. Thus, this model was not used to analyze the CRSO EIS alternatives.

				needs. Known as capacity expansion models, these common software tools allow for power system planners to iterate towards a collection of measures optimized to meet system needs.24 In one of the most glaring failures of the CRSO EIS, the agencies here did not use the capacity expansion tool specifically designed by the Northwest Power and Conservation Council, the Regional Portfolio Model, to assess the optimal portfolio of options specific for the CRS.25 Instead, the agencies use a different tool, GENESYS, that is designed to assess the adequacy of a single option. By using the wrong tool when the right tool is known, available, and specifically designed to address the issue under consideration here, the federal agencies failed to insure the professional integrity, including scientific integrity, of the discussions and analyses in environmental impact statements.	
6722	7	N/A	N/A	The DEIS misrepresents the impact of planned coal generation retirement on regional reliability and resource adequacy. Along with failing to develop adequate, science-based alternatives, the federal agencies applied an unfounded assumption to critique the ability of the alternatives to meet the purpose and need. Maintaining a reliable electric system is a legitimate purpose and need for this DEIS. Where the agencies fail though is in misrepresenting the impact of planned retirement of coal-powered generation plants in the region. The agencies state: without coal, more of the capability or replacement capability of the lower Snake River (LSR) projects would be needed for power system reliability.27 This assumption is demonstrably false. The federal agencies do not have any ownership interest in coal plants, rather regulated utilities in the region own and operate these plants under regulation by their respective state utility commissions. PacifiCorp, who is the primary owner of every coal plant in the region, has an Integrated Resource Plan that documents the path to exit coal plants while maintaining reliable and affordable energy.28 The LSR projects are not a part of the plan, and thus the assertion these dams are needed for reliability is not accurate. By misrepresenting facts in the analysis, the federal agencies here failed to insure the professional integrity, including scientific integrity, of the discussions and analysis in environmental impact statements.	This comment is inconsistent with the findings of the EIS. The comment ignores the rigorous evaluation framework used in the EIS, which incorporates detailed modeling to accurately assess regional reliability as measured through the loss-of-load probability (LOLP) metric under alternative operations of the Columbia River System. GENESYS results show that under Multiple Objective (MO) Alternative 1, MO3, and MO4, the ability of the region to meet load is degraded, and replacement resources would be required in order to maintain regional reliability at the No Action Alternative level. GENESYS is a regional model, and when one resource produces less power, other resources increase generation when necessary and possible to meet load. For MO3 and MO4, even with new renewable replacement resources to maintain regional reliability, the GENESYS model indicates that existing carbon-emitting plants would increase net generation. The base analysis includes all of the coal plants expected to be operational in 2022. Even assuming all coal plants currently in operation remain available throughout the study period (see Appendix H, Power and Transmission, Section 2.3, at Table 2-5 in the draft EIS), regional reliability would decrease without the four lower Snake River dams without additional replacement resources. See draft EIS, Section 3.7.3.5, Effects on Power System Reliability, at page 3-903 and Appendix H, Table 2-1.
6722	8	N/A	N/A	The DEIS does not properly account for the impacts of climate change on generation operations under any alternative. Climate change is not properly addressed in the DEIS analysis of the multiple objective alternatives and the Preferred Alternative. While an analysis of climate change effects does appear in Chapter 4, these 24 TVA IRP at Chapter 6, PacifiCorp IRP at chapter 7, Idaho Power IRP at chapter 8. 25 NWPCC Regional Portfolio Model described in Appendix L to the 7th Northwest Power Plan, available at: https://www.nwcouncil.org/sites/default/files/7thplanfinal_appdixl_rpm_3.pdf 26 40 C.F.R. 1502.24 27 DEIS Appendix H, line 653 28 PacifiCorp 2019 IRP, Chapter 8, available at: https://www.pacificorp.com/content/dam/pcorp/documents/en/pacificorp/energy/integrated-resource-plan/2019_IRP_Volume_I.pdf 29 40 C.F.R. 1502.24 effects are never covered in comparing the alternatives and their relative impacts to power generation and transmission. Chapter 4 shows that climate change will have major effects on both demand for electricity (load) and on the annual hydrograph, causing shifts in annual generation patterns for the CRS projects. Because the Replacement Power Analysis is only based on a single year, 2022, it does not factor in these significant and fairly well-understood trends. Across the 25-year horizon the DEIS claims to analyze when assessing impacts, the River Management Joint Operating Committee (RMJOC) concluded that, compared to present conditions, the spring peak flow would occur earlier, and summer flows would be generally lower.30 Generation is thus expected to be at low levels for longer in the summer. Demand will generally increase in the summer and decrease in the winter as air temperatures rise across the region.31 The DEIS thus acknowledges that generation and load will both be altered by climate change, and in a way that brings CRS generation patterns out of sync with load. The region is predicted to have even higher load during summer, exactly when the CRS is at its low point for generation. The existing hydroelectric system is simply not suited to the task of meeting this load change, and avenues for system change and diversification should be sought to properly adjust. The DEIS, however, simply concludes that climate change does not affect the overall conclusion regarding the net effect of any of the MO alternatives relative to NAA.32 No details about the scope, methodology, inputs, or results leading to this conclusion are provided in the DEIS. Blanket statements without adequate explanation that contradict other information in the DEIS is the hallmark of arbitrary agency action. Beyond the failure to analyze the impact of climate change on the energy system, the DEIS also dismisses any possibility that a replacement power portfolio for the lower Snake River dams could contribute to mitigation for the effects of climate change. The lower Snake River dams are especially vulnerable to such effects, being run-of-river projects that are dependent on upstream storage to regulate flow. A different portfolio of resources could better respond to climatic changes, while diversifying BPAs overall resource mix to better serve the uncertain conditions that climate change will bring alongside well-modeled trends.	As referenced in Chapter 4, Section 4.2.5.1 on page 4-53 in the Draft EIS, the details for the analysis are contained in the Hydropower Appendix. While the Draft EIS incorrectly identified the Hydropower Appendix as Appendix H, the Final EIS correctly references the Hydropower Appendix as Appendix J. Analysis of climate effects on the Preferred Alternative are included in Section 7.8.7 in the draft EIS. The EIS hydropower analysis used four sets of 30-year streamflow records from the RMJOC-II data set (2020-2049, labeled the 2030s). The analysis did not rely on water conditions for the single year 2022. The four scenarios represent a reasonable range of potential climate change impacts and provide a quantifiable basis for understanding how future changes in climate may impact generation. The EIS did not model changes in load associated with climate change because this aspect of the analysis was constrained to 2022. However, as noted by the comment and as described qualitatively in Section 4.2.5.2 in the Draft EIS, Energy Demand (Loads), the changes in temperature would affect demand. The power shortages in winter under all alternatives are likely to be reduced into the 2030s as loads in those months decrease (absent other changes). Conversely, the summer power shortages that increase in MO1, MO3, and MO4 as compared to the No Action Alternative are likely to be further exacerbated as temperatures and load in those months increase and as the low-flow period in summer lengthens. For the Preferred Alternative, the increased reliability in late August could potentially ameliorate projected power shortages in that period due to increasing temperatures and loads. See Section 7.8.7 in the Draft EIS. The EIS did not model hydropower with replacement portfolios plus climate change. The comment is correct that the region needs resources that are able to respond to climate change. Alternatives that increase generation or seasonal flexibility (or both), like MO2, would be beneficial for adapting to the changing hydrograph and power demand associated with climate change. Alternatives that decrease summer generation or seasonal flexibility (or both), like MO3 and MO4, increase the challenges associated with a changing hydrograph. Increases in solar power generation, such as those included in the potential replacement resource portfolios would ameliorate the summer challenges by increasing summer generation.
6722	9	N/A	N/A	The DEIS does not sufficiently analyze the socioeconomic impacts of CRS operations on communities in Idaho that depend on the Snake River, its tributaries, and the runs of anadromous fish that migrate upstream. ICL is similarly concerned that the DEIS did not include nearly enough analysis on the impacts of the alternatives to communities outside the area of the CRS projects, especially Idaho communities on upstream tributaries of the Snake River. Actions taken under any alternative will have major effects on the recreation-based economies of these towns. To a large degree, the recreation economy in towns like Riggins, Orofino, Salmon, Whitebird, and Kamiah is centered on salmon and steelhead: guides, outfitters, and tackle shops cater to anglers wanting to catch fish. Stores, restaurants, gas stations, and hotels rely on the tourist dollars spent in their communities. Collectively, through direct and indirect spending, the dollars spent in these small communities are vital and difficult to replace. Other tourism businesses depend on fish to bring visitors to the area in the first place. Many small communities are nearly entirely dependent on recreational fishing, and will not survive if salmon or steelhead seasons are closed due to the low returns that have become commonplace in recent years. Fish hold inherent value as a species to be seen in these places as well. Recreationists who dont fish are often just as captivated by the thought of seeing a Chinook salmon 900 miles from the ocean. Idahos wilderness and beauty bring visitors to Central and North Idaho for rafting trips, float trips, camping excursions, and retreats. Salmon and steelhead are an integral part of Idahos appeal. The DEIS contains no analysis of how CRS operations impact these places and people. The 2002 CRSO EIS addressed the subject, but now is under apparent doubt from the Action Agencies: In contrast, applying the results of the contingent behavior study conducted for the 2002 EIS would yield an estimate that would range from approximately 1.2 to 3.4 million annual visits (adjusted and unadjusted for population) under MO3 in the long term, depending on whether or not California estimates are included. As described above, the Corps has expressed concerns that the 2002 EIS may have overstated recreation benefits from dam breach. (3-1219) Despite the concerns of the Army Corps, no real reevaluation of these estimates was completed in the current DEIS process, just vague generalizations about past studies. We believe that if this analysis were to be completed again, it would show significant economic benefits to Idaho, Oregon, Montana, and Washington communities related to recovering fish populations. In Idahos rural river towns, even modest amounts of spending related to salmon and steelhead angling are integral parts of the economy. With an improved fishery, Idahos river communities would thrive. This is the only statement in the DEIS that relates improved salmon and steelhead returns to economic benefits for the recreation economy. The MOs that improve fish survival and abundance would generally result in beneficial effects for recreational fishing, while MOs that reduce fish survival and abundance would adversely affect recreational fishing. In particular, the presence of additional fish may improve the quality of existing recreational fishing trips (e.g., through increased catch rates), resulting in additional value (consumer surplus) for anglers (i.e., a higher UDV). Additional fish may also generate additional trips as more anglers could be supported (Melstrom et al. 2015; Poe et al. 2013). (page 3-1181) The DEIS includes no comprehensive economic analysis that goes beyond stating the obvious: more fish make for better fishing. The loosely discussed fishing trips account for $8.6 million per month for B-run Clearwater steelhead alone. Unfortunately, this figure is only known because that fishery was shut down in 2019 due to low returns. Clearwater River communities missed out on the lifeblood of their economy because too few steelhead passed through the CRS on their way back to natal streams in the Clearwater basin. Because the DEIS did not include a comprehensive review of impacts to upstream communities, we can only analyze the economic impact that salmon and steelhead have on Idahos recreation economy based on old data. An Idaho Department of Fish and Game survey shows that in 2003, anglers spent $438 million in direct expenses while fishing in Idaho, broken down as follows33: $148 million spent at restaurants and on groceries $91 million for transportation $60 million for equipment (boats, camping, etc.) $62 million for fishing tackle $45 million on hotels and campgrounds $32 million on outfitters and guides Considering trends in adventure tourism, it is fair to estimate that these totals have significantly increased since 2003, perhaps approaching $1 billion annually. In any given year, there are more than 2,000 licensed outdoor guides working in the state of Idaho. Many of them rely on robust returns of salmon and steelhead, which are almost entirely dependent on CRS operations. The DEIS does not adequately address the economic impact that recreational fishing for salmon and steelhead has on the rural Idaho economy. This is a glaring flaw of the document, and it cannot be considered a comprehensive analysis of how the CRS impacts its environment until it includes a much more robust investigation of these impacts under the alternatives.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
6729	1	N/A	N/A	Hancock Natural Resource Group (HNRG) is a registered investment advisor and an indirect, wholly owned subsidiary of Manulife Financial Corporation. HNRG, and all associated investment divisions and operating entities is committed to responsible investing and sustainable management of its clients assets, including the ongoing reduction of environmental impact and improvement of sustainability and stewardship performance. The HNRG, through its operating entity, Hancock Farmland Services (HFS) manages its clients agriculture investments in a manner that integrates the development, management, and operation of agricultural lands for useful products with a commitment to conserve soil, air, and water quality, biological diversity, and	In Region C (lower Snake River), and potentially Region D (mainstem Columbia River) around the confluence of the lower Snake River, MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams would reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected. Additionally, transportation of farming goods would expect to move off river and on to rail or trucks, as there would be a complete loss of commercial navigation on the lower Snake River and could not be feasibly mitigated. All ports along the Snake River would lose access to the navigation channel. Some ports at the confluence or the Snake and Columbia River could dredge new

				wildlife habitats. HFS also participates actively in the vibrant, healthy communities in which we operate. Through its prominent agricultural lessees, HFS irrigates land along the Ice Harbor-McNary Pools, Lower Snake River. These private sector operations are among the most productive and efficient irrigated properties in the world. Consequently, HFS is highly concerned about any operational changes made by the Columbia River System Operations (CRSO) agencies affecting Pool elevations and flow operations via the ESA-BiOp review alternatives. The alternatives, involving either breaching Ice Harbor Dam or lowering McNary Pool to minimum operating pool (MOP), would severely impact irrigation pumping. HFS holds a Board of Director position on the Columbia-Snake River Irrigators Association (CSRIA), and we have approved the technical/policy analysis provided to the CRSO agencies by CSRIA, per the CSRIA Risk Mitigation Response Alternative White Paper (CSRIA.org/ESA Risk Mitigation). In this White Paper, CSRIA explicitly identifies the required EIS and economic analysis methodologies, the impact area, and the impact mitigation economic valueall of which should be included within the EIS irrigation sector review. Very specifically, the Draft EIS existing irrigation sector impact area is incorrect. While the Ice Harbor Pool irrigated acres are slightly less that the CSRIA estimate (about 54,000 acres), the Draft EIS fails to account for the McNary Pool acres (about 37,000) that will be affected by breaching/pool drawdown. Under dam breaching, it is not realistic to expect the reach below Ice Harbor Dam to the mainstem Columbia River to remain stable or the same as under existing physical conditions. The inflows to this reach will be at a much higher water velocity, coming from a much narrower channel, and with very high silt and debris concentrations. Irrigation pumping stations along the entire impact area, including the Upper McNary Pool reach, are highly sensitive to pool elevation drawdowns and siltation issues. The MOP operations will definitely impact the pump stations and conventional operations. These are high dollar impacts. Consequently, while there are many technical, policy, and political issues at play within the EIS analyses, the impact area must be correctly identified.	channels to the Federal channel in the confluence (McNary reservoir) to maintain access. Private or public entities or businesses could take actions or build infrastructure to extend pumps or water supply access for water. Ports and farmers can likewise change their transportation modes or connect to the navigation system at a different point on the river. The federal co-lead agencies would not mitigate for these impacts to water users or ports. Chapter 3 analyzes the social and economic effects of implementing a dam breaching alternative (MO3) and Chapter 5 includes the mitigation that could be necessary if MO3 was selected. The co-lead agencies did not identify MO3 as the Preferred Alternative.
6730	1	westphalbri@gmail.com	N/A	Since my major complaint is that the Preferred Alternative is predetermined based on meeting the objectives given, I, as a commentor can have the same preconceived notion, that is, what conclusion meets the only real environmental objective: SAVE THE FISH! Recall that the National Environmental Policy Act (NEPA) process is all about the environment and as such this EIS should not be addressing power output, water management, and water supply as primary objectives since they are not directly related to the environment. The purpose of NEPA is to promote efforts which will prevent or eliminate damage to the environment and biosphere. Giving objectives such as power and water management the same weighting as salmon, lamprey, and emissions goes against NEPA. I understand the indirect effects power and water management may have to the environment but don't understand how they are on equal footing to direct effects on the biosphere. As such, I believe the current NEPA evaluation is in direct violation of the intent of NEPA. A graded system wherein fish priorities (biosphere) are given higher emphasis than non-environmental considerations such as power should have een mplemented and evaluated, so that rigorous analyses could have been performed on the objectives.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. As required by the National Environmental Policy Act (NEPA), the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapters 3, 4, 5, 6 and 7; summarized by resource and alternative in Table 3-1, and presented for comparison in Tables 7-1 and 7-55 in the Draft EIS. Effects specific to anadromous fish are described in Sections 3.5.3 and 7.7.4. In the Draft EIS, Table 3-61 compares expected survival by alternatives, and Table 3-62 provides a comparison of the alternatives specific to anadromous fish. The EIS considered the impact of all of the actions and measures in the alternatives for a multitude of ecological resources, such as water quality and fish, as time progresses from implementation into the future. There are many ecosystem and individual resource effects that occur outside the operation and maintenance of the CRS. Salmon and steelhead and other resources have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat (see Chapters 6 and 7 for additional information). The co-lead agencies analyzed the effects of the operation, maintenance, and configuration of the CRS projects on resources affected by the CRS. The co-lead agencies also looked at the cumulative effects of past, present, and reasonably foreseeable future actions and trends in Chapter 6 (Cumulative Effects) and Chapter 7 (Preferred Alternative), of the EIS. Further, Chapter 4 (Climate) provides an overview of the project changes in future regional climate and discusses how these changes would affect each of the resources under each alternative.
6730	2	westphalbri@gmail.com	N/A	To quantify my comments: 1) By including non-environmental considerations such as power and water management as primary objectives, the NEPA process was clearly not followed. If inclusion is necessary for indirect environmental effects of these objectives, then a weighting system should be applied such that less merit is given to these objectives than to the other five primary objectives (fish, lamprey, and emissions). A thorough technical evaluation of the objectives would have prioritized their importance as related to NEPA and applied a graded approach to their merits in meeting the NEPA process. Then, as results are tallied based on the relative importance of the objectives, a true evaluation of the alternatives on the effects to the environment would have been possible. 2) Although I recognize that the Bonneville Power Association (BPA) is a governmental agency, it has one purpose: to produce and sell power. To include the BPA as a contributor to the EIS is like asking the wolf to lend house building suggestions to the three little pigs. The EIS should never have included BPA input. 3) Since implementation of protocols to increase fish (and lamprey) survival rates have only been instituted in the last 5 years, drawing conclusions on their effectiveness is premature at best and irresponsible to say the least.	First, the commenter misunderstands what effects must be considered as part of an EIS. As the Council on Environmental Quality's NEPA regulations state, "[ef]fects include[] ecological (such as the effects on natural resources and on the components, structures, and functioning of affected ecosystems), aesthetic, historic, cultural, economic, social, or health, whether direct, indirect, or cumulative." 40 C.F.R. 1500.8). Thus, the CRSO EIS appropriately analyzed economic effects. Second, the commenter misunderstands the varied and complex mission of the Bonneville Power Administration (Bonneville). Bonneville is a nonprofit federal power marketing administration based in the Pacific Northwest. Although Bonneville is part of the U.S. Department of Energy, it is self-funding and covers its costs by selling its products and services. Bonneville markets wholesale electrical power from 31 federal hydroelectric projects in the Northwest, one nonfederal nuclear plant and several small nonfederal power plants. The dams are operated by the U.S. Army Corps of Engineers and the Bureau of Reclamation. The nonfederal nuclear plant, Columbia Generating Station, is owned and operated by Energy Northwest, a joint operating agency of the state of Washington. Bonneville provides about 28 percent of the electric power used in the Northwest and its resources primarily hydroelectric make Bonneville power nearly carbon free. Bonneville also operates and maintains about three-fourths of the high-voltage transmission in its service territory. BPAs territory includes Idaho, Oregon, Washington, western Montana and small parts of eastern Montana, California, Nevada, Utah and Wyoming. Bonneville promotes energy efficiency, renewable resources and new technologies that improve its ability to deliver on its mission. It also funds regional efforts to protect and rebuild fish and wildlife populations affected by hydropower development in the Columbia River Basin. Bonneville is committed to public service and seeks to make its decisions in a manner that provides opportunities for input from all stakeholders. In its vision statement, Bonneville dedicates itself to providing high system reliability, low rates consistent with sound business principles, environmental stewardship and accountability. And finally, implementation of protocols to increase fish and lamprey rates has been around much longer than five years. The co-lead agencies relied on high quality information in their fish and lamprey analysis. See Sections 3.5 and 7.7.4.
6739	1	cindy@orcanetwork.org; Howard Garrett	Orca Network	We would first of all like to express our disappointment that the comment period was not extended beyond April 13th. At only 45 days, the time allotted for this comment period was not sufficient to fully read and understand a document of this magnitude. Given current events with the pandemic and the inability to host inperson public meetings, we felt that the public needed more time to read and digest this information and give it the attention it deserves so they could prepare educated and thoughtful comments.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
6739	2	cindy@orcanetwork.org; Howard Garrett	Orca Network	We would also like to express our disappointment that the DEIS did not adequately represent the importance of Columbia Basin salmon to the endangered Southern Resident orcas, and it fails to recognize the biological need of Southern Residents to have continuous access to salmon from a variety of river systems throughout their range. 2 Southern Resident orcas are a genetically, acoustically, socially, and culturally distinct population of fish-eating orcas. They were listed as endangered under the U.S. Endangered Species Act in 2005 but are continuing to decline despite the protection and recovery actions initiated by this listing. In 2019 the population dropped to just 73 orcas, the lowest number in four decades 1, and the Center for Whale Research announced in January that an adult male may be missing from L Pod. Their main threats include a lack of available prey, namely due to a decline in their primary prey, Chinook salmon; environmental contaminants, particularly bio-accumulative organochlorines such as DDT, PBDEs, and PCBs; and vessel effects and sound, as well as increased potential for oil spills and disease. 2 Of these threats, lack of prey is widely recognized as the biggest limiting factor in their recovery. Salmon depletion has led to changes in their social structure, decrease in presence in their core summer feeding areas, an increase in stress hormones and a miscarriage rate of almost 70%.3 In the 2008 Recovery Plan for the Southern Resident Orcas, the National Marine Fisheries Service (NMFS) stated that perhaps the single greatest change in food availability for resident killer whales since the late 1800s has been the decline of salmon in the Columbia River basin. NMFS also stated that Columbia-Snake River Basin salmon has the largest potential for increasing Chinook salmon abundance throughout the Southern Residents range.4 Yet the CSRO DEIS states that Puget Sound Chinook salmon stocks are more important to Southern Resident orcas than Snake River stocks due to their availability for greater periods of the year and also claims that the food available to Southern Resident killer whales from the lower Snake River population is only a small percentage of their overall diet. Changes to food availability may change the whales foraging behavior patterns slightly but will not change their overall condition or population dynamics.5 We know from a variety of research and data sources that Southern Resident orcas spend over half the year in coastal waters and that Columbia basin salmon make up over half of their outer coastal diet. Photogrammetry studies show that the Southern Residents are experiencing a decline in body condition between October and May.6 Data from sightings, acoustic recordings, satellite tagging, and prey and fecal samples show that they are traveling primarily in coastal habitat during this time, and that Chinook salmon continue to be the preferred prey in these waters, further underscoring the need for an abundant, healthy food source throughout their range.7 Data from the National Oceanic and Atmospheric Administration (NOAA) compiled from satellite-tagging studies, dedicated surveys, and passive acoustic monitoring from hydrophones located in coastal waters shows that all three pods in the Southern Resident population use the coastal waters of Washington year-round, with the highest use occurring during the winter and early spring.8 The data indicates that, of the total time the orcas spend in coastal habitat each year, approximately 50% of that time is spent off the coast of Washington, and NOAA has identified this as a high-use foraging area for the population.9 The concentration of use of the waters between Grays Harbor and the mouth of the Columbia River appears to be driven by the timing of seasonal Chinook runs, and the Columbia and Snake River are listed as priority Chinook stocks for Southern Resident orcas.10. We also know, as evidenced particularly in 2018 and 1 Center for Whale Research Orca Survey data 2 National Marine Fisheries Service. 2008. Recovery Plan for Southern Resident Killer Whales (Orcinus orca). Using aerial photogrammetry to detect changes in body condition of endangered southern resident killer whales. 7 National Marine Fisheries Service Biological Report, 2019. Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales. 8 Proposed Revision of the Critical Habitat Designation for Southern Resident Killer Whales: Draft Biological Report. National Marine Fisheries Service, September 2019. Available: https://www.fisheries.noaa.gov/action/critical-habitat-southern-resident-killer-whale 9 Hanson, M.B., E.J. Ward, C.K. Emmons, and M.M. Holt. 2018. Modeling the occurrence of endangered killer whales near a U.S.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS analysis found that only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8.

				Navy Training Range in Washington State using satellitetag locations to improve acoustic detection data. 10 NOAA Fisheries and Washington Department of Fish and Wildlife 2018. Southern Resident Killer Whale Priority Chinook Stocks Report. 3 2019, that Southern Residents will shift their patterns and feed off the coast during the summer when there is little to no salmon available in the Salish Sea, underscoring the importance of these coastal runs as Puget Sound and Fraser River stocks continue to decline or fail to improve.	
6739	3	cindy@orcanetwork.org; Howard Garrett	Orca Network	Of the alternatives presented in the CRSO DEIS, MO3, Snake River dam breaching plus increased spill over the Columbia River dams, represents the best chance of recovery for Snake River salmon and for Southern Resident orcas. The benefits of dam breaching were demonstrated in a recent white paper entitled Southern Resident Killer Whales & Columbia/Snake River Chinook: A Review Of The Available Scientific Evidence which was written by five PhDs and submitted earlier this year.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020).
6757	1	N/A	N/A	The following are comments specific to the scope and findings of the Draft EIS. Draft EIS Scope The Agencies decision to exclude the Upper Snake River and its tributaries from the analysis of the Draft EIS is appropriate. It is wisely noted that the Upper Snake River, amongst other basins, are operated separately and have entered into their own agreements, coordination programs, and management efforts. The Nez Perce Agreement, which was ratified by Congress in 2004, settled much of the tribal water disputes above Hells Canyon. The agreement consists of specific provisions/requirements, including flow augmentation, and the establishment of a 30-year biological opinion that is extendable. Appropriately, the CRSO Draft EIS excludes the Upper Snake River from the scope of consideration, as to not interfere with such Congressionally approved agreements.	Thank you for your comment.
6757	2	N/A	N/A	Additional Flow Augmentation The topic of flow augmentation is one that has troubled our members for years. Research has not shown any significant biological benefits to increased stream/river flows. Additionally, the Draft EIS provides little, if any, information as to how flow augmentation supports species listed under the Endangered Species Act. For this reason, we question its proposal and inclusion in several of the alternatives, particularly Alternative 4. IFBF Policy supports reevaluating the use of flow augmentation until the science shows a benefit to the intended species of concern. Any flow regime that is considered in the final EIS must be both scientifically justifiable and comply with state water law. IFBF opposes Alternative 4 and any additional flow augmentation requirements not supported by science as they would have severe negative effects on water rights and other uses.	Flow augmentation from all the storage projects upstream does provide some benefit downstream. It is a required operation under the Biological Opinions to help provide additional flow for downstream fish, both directly below the project and in the lower river. Multiple Objective Alternative 4 was not identified as the Preferred Alternative due to its impacts upstream and not creating additional benefit in the lower river.
6765	1	john@snakeriverboard.org	Snake River Salmon Recovery Board	Specific comment and data sources for consideration in the draft EIS: Adult salmon and steelhead tributary overshoot in the Middle Columbia and Snake Basins, as it pertains to the Tucannon populations of summer steelhead and spring Chinook salmon and Walla Walla populations of steelhead are largely over-looked in the EIS document. Some mention of fallback was covered in the following: [letter contains screen shot of lines 2723-2732 of the DEIS] The preferred alternative indicates a potential increase in fallback, but the impacts on overshoot are not discussed. Overshoot needs to be defined in the document, as it is distinctly different than homing, fallback, or straying whereby fish that overshoot their natal tributary are not fish that are part of the natural straying population, rather fish that seek to return downstream but have no adult downstream fish passage opportunity. Estimates of mortality related to overshoot for the Tucannon River wild and hatchery summer steelhead show that in some years more than 50% of adult steelhead returning to Ice Harbor Dam pass the Tucannon River, Little Goose and Lower Granite Dam. Returns of fish to the Tucannon River of fish that are detected above LGD often ranges between 0%-20%. (Copeland et al., 2013). Investigation of mortality related to both overshoot and kelt emigration should be warranted in the Lower Snake Basin to better understand the mechanisms causing overshoot and how to improve survival in spawning tributaries as well as repeat spawners. Year-round fish passage, upstream and downstream, should be considered in the preferred alternative. Line 7273: These data do not accurately represent survival of Snake River or Mid-C stocks that are losing individuals that overshoot and result in increased mortality or inability to fallback downstream to natal rivers. Data cites straying but it is unclear if this category includes overshoots that do try to navigate back downstream to natal rivers at a later date. Tucannon stocks in particular have as much as 50% overshoot (Richins and Skalski, 2018). [letter contains screen shot of these lines in the DEIS] Pg. 3-299, Line 7714: Much of the life history discussion skips over the effects of repeated dam passage and fallback by Mid-Columbia and Snake River populations. While this example is correct in that Snake River steelhead will encounter 8 dams, the fish that overshoot must navigate back through the hydropower system, often with the only downstream passage available being through turbines which lead to greater risk of injury. The Tucannon steelhead were briefly mentioned, however its worth highlighting that as many as 50% of fish will bypass the mouth of the Tucannon and proceed beyond Lower Granite (Bumgarner and Dedloff, 2011). [letter contains screen shot of these lines from the DEIS] Line 9783: It is important that these models incorporate population differences in how fish experience and navigate dams as adults. Mid-Columbia steelhead and Tucannon steelhead show higher overshoot rates than other populations and therefore are at a higher risk of not reaching their intended spawning areas whether it be due to injury passing through hydropower system, or inability to navigate back and becoming lost to the intended population. Some model pieces used existing DPS to project effects on other populations which may not be giving an accurate picture of adult survival (Bumgarner and Dedloff, 2011). [letter contains screen shot of DEIS] Line 9906: Models dont appear to consider the effects of overshoot and repeated navigation back down through dams by adult fish. Particular emphasis should be given to Tucannon stocks that see a large portion of fish migrate over Lower Granite and very few (20%) returning to the Tucannon. It does not appear that the models or MOs capture the different effects on adult overshoots. (Bumgarner and Dedloff, 2011). [letter contains screen shot of DEIS] Line 9943 Table 3-60: This may not be an appropriate option. Different ESU/DPS have differing rates of passage, straying, and overshoot so a surrogate will not capture the unique differences among populations (Keefer and Caudill, 2013; Bumgarner and Dedloff, 2011). [letter contains screen shot of DEIS]	Section 7.6.4.3 describes preliminary measures agreed to by the co-lead agencies during informal ESA consultation with NMFS and USFWS on the Preferred Alternative. Due to the fact that the consultation is ongoing, the measures in this Section may be modified prior to the Final EIS. In the case of steelhead overshoots (and kelts), this Section includes the following: To reduce the take of overshooting adult Middle Columbia River and Snake River Basin steelhead, the co-lead agencies, beginning in 2020, would implement offseason surface spill as a means of providing safe and effective downstream passage for adult steelhead that overshoot and then migrate back downstream through McNary Dam and the Snake River dams during months when there is no scheduled spill for juvenile passage. The co-lead agencies would implement this measure within the October 1 to November 15 and March 1 to March 30 timeframes based on the analysis already included in this EIS for MO4. The commenter is correct that the model analyses do not accurately or fully capture the effect of the dams on the escapement of adult steelhead overshoots and kelts. These effects of dams on escapement of adult steelhead overshoots and kelts are discussed qualitatively in the Draft EIS.
6765	2	john@snakeriverboard.org	Snake River Salmon Recovery Board	Line 10109: This should also be highlighted as a major concern in the Snake River System as noted in Erhart 2018. [letter contains screen shot of DEIS]	The co-lead agencies recognize the importance of predation by piscivorous predators and evaluated this factor in the Snake River as well as the Columbia River. This statement in the "Effects Common to All" Section is intended to be more broad and inclusive of the entire Columbia River Basin (including the Snake River) as it applies common to all salmon and steelhead. The analyses of resident fish populations are considered specific to Snake River fish in Region C of the resident fish analyses and applied to anadromous fish in the "Snake River Salmon and Steelhead" Sections under Anadromous Fish, all in Section 3.5.3.
6765	3	john@snakeriverboard.org	Snake River Salmon Recovery Board	Line 10623: While this section does talk about ST kelts navigating downstream, it doesnt talk about the issues with pre-spawn overshoots or fallback issues. For particular populations, the portion of fish that must successfully navigate back down through a hydropower dam is significantly greater than other populations and should be acknowledged as such. None of the MOs discuss ways to reduce likelihood of fish that bypass and then do not navigate back down. Regarding Kelts, it is previously noted that up to 50% of post-spawn steelheads are indeed kelts. It is unclear if the models accurately capture the potential importance of this particular life history characteristic-particularly when those fish will have to try and successfully navigate back down all of the hydropower dams (Bumgarner and Dedloff, 2011). [letter contains screen shot of DEIS]	The commenter is correct that none of the MOs included specific measures to improve downstream adult steelhead overshoot passage. That is because this is an ongoing action that will be carried forward from the No Action Alternative. Section 7.6.4.3 describes preliminary measures agreed to by the co-lead agencies during informal ESA consultation with NMFS and USFWS on the Preferred Alternative. Due to the fact that the consultation is ongoing, the measures in this Section may be modified prior to the Final EIS. In the case of steelhead overshoots (and kelts), this Section includes the following: To reduce the take of overshooting adult Middle Columbia River and Snake River Basin steelhead, the co-lead agencies, beginning in 2020, would implement offseason surface spill as a means of providing safe and effective downstream passage for adult steelhead that overshoot and then migrate back downstream through McNary Dam and the Snake River dams during months when there is no scheduled spill for juvenile passage. The co-lead agencies would implement this measure within the October 1 to November 15 and March 1 to March 30 timeframes based on the analysis already included in this EIS for MO4. The commenter is correct that the model analyses do not accurately or fully capture the effect of the dams on the escapement of adult steelhead overshoots and kelts. These effects of dams on escapement of adult steelhead overshoots and kelts are discussed qualitatively in the Draft EIS.
6765	4	john@snakeriverboard.org	Snake River Salmon Recovery Board	Line 13054: There is no mention of predator modifications for Snake dams (avian or aquatic). This should also be highlighted as a concern in the Snake River System, see Erhart, 2018. Northern Pike will also pose a major problem if they continue to spread. It seems that a greater consideration of the impacts of non-native fish predators is warranted in this document. The following tables list the measures being carried forward in the preferred alternative (Table 7-5, Measures Included in the Preferred Alternative to Benefit Endangered Species Act-listed Fish that are Being Carried Forward from Previous Commitments by the Co-Lead Agencies, Line 7-41) and the ones being considered. (Table 7-6, Preliminary List of Measures Agreed to by the Co-Lead Agencies during Endangered Species Act Consultation on the Preferred Alternative, line 7-46). Given the known predation of salmonids in the Columbia and Snake Basin, no measures are provided to address nonnative fish predation on salmonids. Measures are included on controlling native	The Preferred Alternative has multiple measures targeting reducing predation rates (from both birds and fish) in the McNary and John Day pools. The bird dissuasion measures at both the Columbia and Snake river hydropower projects are slated to continue under the Preferred Alternative. These actions are intended to reduce predation on juvenile salmonids while they are in the immediate vicinity of the lower Snake River projects and are at potentially higher risk of predation. There is no or very limited nesting by avian predators within the lower Snake River region (few cormorants at the mouth of the Clearwater for example), but from a colony/habitat focus, attention is in the Columbia where the nesting colonies are located (plus off channel locations such as Potholes). As a result, there is not much data for direct measure of avian predation within the lower Snake River directly; breeding/nesting terns, cormorants, gulls, and pelicans foraging in the lower Snake River are believed to come from the respective nesting colonies on the Columbia and at off channel locations. For more information see Chapter 5 of the 2004-2009 Synthesis Report on the abundance, distribution, and diet composition of cormorants over-wintering on the lower Snake River. http://www.birdresearchnw.org/Avian%20Predation%20Synthesis%20Report%202004-2009%20Final%20v2.pdf BPAs Northern pikeminnow program includes the lower Snake River reservoirs and there are multiple sport reward stations throughout the lower Snake River region.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				fish (i.e. pike minnow) control and native avian and marine mammals, although they could be bolstered as this is of significant concern (Chasco et al. 2017). Specifically, reducing predation rates (from both birds and fish) in the McNary and John Day pools and lower reaches tributaries is needed. Consideration should be given to impacts of non-native warm water fish predation and the impacts to Snake River Spring and Fall Chinook. Studies have shown juvenile Chinook and particularly age zero fall Chinook are consumed at a high rate by smallmouth bass. The study estimates (based on empirical evidence of the study), that between April 2013 to September 2015 more than 300,000 chinook salmon were consumed in Lower Granite Reservoir. The study supports an increasing rate of consumption of chinook by smallmouth bass and not an increase in abundance. This mortality rate could be reasonably expanded to the rest of the lower Snake and Columbia as well since walleye another efficient predator. These studies support reduced feeding efficiency during periods of increased flow and reduced temperature (Erhart, 2018).	
6767	1	gregg.larson@mcg.com	N/A	We first need to acknowledge that dam power is NOT CARBON-FREE! This mistruth has been continued in the report and propagated from those that support the stats-quo failure of salmon that are nearly extinct in the Snake River.	The EIS considers that hydropower does not emit carbon through the process of generating electricity. However, the emissions analysis considers the potential effects of methane emissions from hydropower reservoirs. Appendix G, Chapter 5 of the Draft EIS details the assessment of reservoir methane emissions from the Columbia River System projects. The findings are summarized in Section 3.8. This assessment finds that reservoir characteristics and management substantially influence methane emissions, so methane emissions vary by site. A 2016 study developed by the Corps' Walla Walla District concluded that for the relatively clean reservoirs of the Federal Columbia River Power System, which include the lower Snake River dams, conditions for low dissolved oxygen concentrations are not prevalent; thus methane gas is generally not an issue. Additionally, in 2017, the Northwest Power and Conservation Council found that data on these sites were insufficient to estimate the reservoir methane emissions specifically for the Columbia River System but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies would allow for better measuring and understanding the effects of reservoir methane emissions from Columbia River System projects, including the four lower Snake River dams.
6773	1	wwpinneys@gmail.com	N/A	For so many legitimate and legal reasons I wish to add myself to the vast long requesting list that this deadline date must be pushed out to 15 June or 1 July (how about 4 July fireworks to celebrate dam decommissioning?).	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
6773	2	wwpinneys@gmail.com	N/A	The time scale used for the comparative analysis of the four MOs to the No Action Alternative is a 25-year period from 2020 to 2045. For the purposes of conducting the economic analysis, a 50-year period of analysis is used to better capture the full array of changing costs and investments, and represent the total costs, benefits, and tradeoffs being evaluated in each of the MOs. Pg 3-1. Costs out 50 years (unforeseen or unplanned) cannot be estimated or incorporated but likely can significantly influence selection of Preferred Alternative, unless PA was preselected by design as this case strongly indicates.	The Preferred Alternative includes a combination of measures that meet the Purpose and Need and objectives of the Columbia River System Operations (CRSO) EIS, while balancing the authorized purposes of the 14 Federal dam and reservoir projects that make up the CRS. The temporal scope of the EIS is assumed to be 25 years from the signing of the Record of Decision (ROD) in order to have a similar period of analysis for comparison of effects across resources for all multiple objective alternatives. The 50 year time scale for economics is to understand investments annualized. For instance, large construction costs, such as dam breaching, look disproportionately high without looking at the life of the cost and changes of investment. Additionally, maintenance cost could be lost or under-calculated without capturing the life of a project.
6773	3	wwpinneys@gmail.com	N/A	The NAA is not the baseline for which to adequately compare effects to any of the resources, either beneficial or detrimental, especially for wild salmon and steelhead because NAA has been determined Jeopardy to the ESA-listed ESUs and DPS in the Court Order and all the BiOps that have been remanded.	The No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change. For this EIS, the No Action Alternative describes the operation, maintenance, and configuration of the CRS, from September 30, 2016, the date the Notice of Intent to complete the CRSO EIS was published in the Federal Register. The No Action Alternative is required by the National Environmental Policy Act (NEPA), in accordance with the Council on Environmental Quality regulations (40 Code of Federal Regulations [CFR] 1502.14). The co-lead agencies assume that, to the extent possible, all ongoing, scheduled, and routine maintenance activities for the Federal infrastructure and all structural features, including those recently constructed or reasonably foreseeable, are included in the No Action Alternative. The No Action Alternative provides a baseline condition for comparing environmental effects of the action alternatives, or MOs and the Preferred Alternative. The No Action Alternative assumes the CRS will continue to be operated for all congressionally authorized purposes, requiring a balancing of operations across the 14 projects within the CRS. Current operations include actions agreed to in previous ESA consultations among the co-lead agencies, National Marine Fisheries Service (NMFS), and U.S. Fish and Wildlife Service (USFWS). NEPA and the ESA are distinct laws that treat baseline conditions differently; thus, the agencies appropriately applied the NEPA standards to the No Action Alternative (i.e. status quo for an ongoing action). The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.
6773	4	wwpinneys@gmail.com	N/A	Peaking, Ramping, Balancing, & Reserve hydropower benefits of the Lower Snake River Dams (LSRDs). - Claimed over 2,000 MW with a value of $966 million for replacement cost. - Inconsistent with claimed 15 MW in 2002 EIS, Waddell et al. 2020 Claims of Sustained Peaking, Ramping, Reserve, Flexibility and Balancing Power from the lower Snake River Dams, What Is Feasible?	The EIS power analysis relies on historical data on the ramping and flexibility of the four lower Snake River dams. Table 3-160 in Section 3.7.3.5 of the draft EIS presents the historical sustained ramping capability of the four lower Snake River dams. The value of this flexibility was calculated using recent rate information from Bonneville's BP-20 rate case and 2030 LT Aurora runs. See draft EIS, Section 3.7.3.5 at page 3-910, and Tables 3-163, 3-164. Contrary to the statement in the comment, the 2002 EIS identified the lower Snake River dams as 15 percent, rather than 15 MW, of the Federal Columbia River Power System ramping capacity.
6773	5	wwpinneys@gmail.com	N/A	Recreation Visitation Estimated at 2.4 million non-local visitors/year for LSRDs. - 2.4 million visitors is more than those going to Mt Rainier, 6,575 visitors every day. - Data from 2002 EIS since corrected to 53,000 visitors/year by Earth Economics 2016 National Economic Analysis of Four LSRDs. - Used to extrapolate Multiple Objective 3 (MO3) losses of 1,420 jobs, $59 million in labor income, and $189 million in annual sales. No benefits quantified, though 3-4,000 jobs would be created (Earth Economics 2016). - The slope, aspect, and confinement (with a couple deeply imbedded canyons that are spring fed and historically had the highest density of indigenous tribal fishing camps and site) characteristics (1935 Dept of War river sounding survey sheets on milar originals and digitized layer files for the 3-d fluvial geomorphic and MASS2 models used in 2002 FR/DEIS and FEIS for the Snake River App H and other Appendices and main synthesis text, PNNL-Battelle and Corps Walla Walla) resulting from the selection and implementation of MO3 to re-setting the restored LSR geomorphology, rapid-run-pool habitats, natural river hydraulics, and the juxtaposition of the LSR to quite a substantial number of well-established present day and historically viable white water outfitters (along the Clearwater and Salmon rivers and within Lewiston, Moscow, other smaller towns, as well as Boise), as well as substantial boons in canoe and drift boating for families, and other highly-used popular white water recreation activity streams where these operators boat (i.e., Lochsa, Selway, Salmon, Grande Ronde, et al rivers) would far out-economy grow the present narrow pooled water use area that is concentrated only off-shore within the pool-to-free flow transition reach located between southern Lewiston, ID and south-eastern Clarkston, WA. Only during the hottest summer months of July through August is this narrow and short stretch of very limited and over-packed to the point of highly dangerous footprint of stagnant waters used. The swimming beaches are routinely closed for the over-concentration of, rapid growth of, and accumulation of the usual water quality constituent contaminants, such as swimmers itch, giardia, et al. Restoring MO3 would significantly restore and extend the white water based recreation use and economics to those towns several magnitudes exceeding the present rec conditions in the over-extrapolated opinions of the Ports and their lobbying entities just if one only considers the fact that white water would be allowable and exciting to raft and boat and float on 140 miles of restored free-flowing river for 6-9 months each year as opposed to the restricted and very densely used and dangerous 1-2 miles of impounded transitional pool between Lewiston and Clarkston. The vastly increased and restored Free-flow related water borne recreational opportunities afforded under MO3 would realistically be quite similar to the increasing magnitude of sport-fishing access and successful catch rates afforded by shoreline and boat accessed fishing for all ranges of ages within the public. - Dreamed up woes of too much sediment and garbage (smells) in the breached and drawn down channel off Lewiston and Clarkston are simply chicken-little tactics. Yes, there will be transformers, shopping carts, and rubbish up to discarded cars in the channel restricted near the city reaches constituting the Clearwater and Snake rivers confluence, as witnessed by the actual researchers working the 1992 Drawdown Test (archived photography @ Corps-Walla Walla), just as the construction works and bureaucrats working during each construction activity phase of each LSR dumped and deposited (leftovers) a great deal of rubbish piles and heavy equipment (liquid drained bulldozers, cement mixers, even at least one wrecked airplane, etc, including an encapsulated fill of contaminated materials). Yes, all this needs requirements for clean up just like it should never have been human-placed in the first place. These dumpings are not the rivers fault, or the rivers doing based upon river function and ecology, but were the human citizens of Lewistons and Clarkstons inappropriate behaviors through a couple decades of time purposely abusing the stealthy opportunity of depositing rubbish under water where it would be site-unseen, at least until a breach. Again, a result of lack of (and intent not to) enforcing local laws and state and federal Acts and statutes.	As described in Table 3-256, visitation at Lower Granite accounts for over 60 percent of visitation at the four lower Snake River projects. The Corps counts visits as recreation visitor days for all non-campers. For example, two people boating on a reservoir for two days would count as four visits. For campers, consistent with NPS visits, campers are counted per night. That is a party of two stay for two nights is counted as four visits. This may account for relatively higher number of visits as each day that a person visits is counted as a "visit." The visitation data comes from Corps sources, including traffic counters and visitor use surveys and includes the most up to date visitation data available at the time of the analysis. It should be noted that project visitation data (at each reservoir) includes recreation areas on the reservoirs as well as recreation areas located above the lake or below the dam in the river reaches. Section 3.11.3.5 describes the impacts under MO3 in the long term when the transition to river conditions is complete. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. This visitation in the long-term is predicated on the need to developed access to the river resource. However, a specific estimate of river-based visitation was not provided because of the uncertainty and the large range in potential visitation. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. Visual resources and noise resources are described in Sections 3.13 and 3.14, respectively.
6773	6	wwpinneys@gmail.com	N/A	MO3 anadromous fish mitigation with additional hatchery salmon, cost of 78.1 million. - Absent in the 2002 EIS breach alternative because appropriate timing is in winter, when almost no fish are in the river. Breaching is the mitigation, preventing the death of ~8 million chinook smolts per year.	The breaching would be timed as well as can be controlled to take place outside of the migration period. However, the hatchery fish mitigation is to provide fish during the short-term effects associated not with the demolition, but the flushing of stagnant water and sediments as the reservoir elevation drops substantially, anticipated to drop dissolved oxygen levels in the water column significantly, and potentially cause 2-7 years of no biological productivity and aquatic losses. Description of these effects are in the Multiple Objective alternative 3 analysis for water quality and fish in Chapter 3. The method proposed for breaching the four lower Snake River dams is based on extensive analysis completed for the 2002 Feasibility Study, which also considered dam breaching. The methodology developed is intended to minimize impacts to ESA-listed fish runs, other aquatic organisms and the built environment, while providing maximum protection to human health and safety. The CRSO EIS uses the same assumptions.
6773	7	wwpinneys@gmail.com	N/A	Lines 16542 to 16554 is just another derived scare tactic derived by BPA solely towards the states and tribes and fishermen. BPA does not fund mitigation hatcheries of USFWS, the Lower Snake River Compensation Plan (LSRCP) hatcheries the Corps built as mitigation to harvestable salmon numbers due to the construction of the 4 lower Snake River dams and Dworshak dam. Yes, detrimental poorly managed hatcheries such as Lyons Ferry (although deemed as an index for the ocean and mutual harvest plans with Canada by being included in their FRAModel) needs to cease and be closed for its horrible impacts on wild salmon populations production related to quite bad broodstock choices among many systemic problems, it is that bad.	Hatchery programs are included in the No Action Alternative and would be expected to continue under alternatives MO1, MO2, and MO4, and certain hatcheries would continue under MO3. No new hatchery programs are considered as mitigation under any alternatives, but MO3 does include increased hatchery production due to short-term impacts from breaching the four lower Snake River dams. Diversity is an important factor in an ESU's ability to persist and adapt, and is one of the factors considered in assessing an ESU's long term viability, along with abundance, productivity, and spatial structure. There is an extensive body of literature developed from studying these factors and managing the conservation of salmon and steelhead, including hatcheries as one tool. Hatchery programs have long been a part of the approach for salmon recovery. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				But realistically, there is a strong legal argument that the Corps would remain on the hook for funding, at least to the point of property transfer, certain mitigation hatcheries such as the two at Dworshak dam, since they were funded as mitigation for projects other than the Snake River or complexed with the Snake River mitigation. Mitigation cannot just go away without some transfer because the effects of the existence and operation of the four LSR dams across the decades do not magically go away until the point that either the mitigation plan is fully completed or the salmon and steelhead recover to the populations escapement, diversity, and productivity vitalities of the river environments pre-dam year.	proposed under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery programs are proposed. Figure 3-111, which combines hatchery and wild fish, in the Draft EIS was an illustration that the CRS can and has supported large numbers of returning adult salmon and steelhead. Over time, the Preferred Alternative is anticipated to benefit both wild and hatchery fish. Hatchery origin fish are very important to tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. The three co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS. The co-lead agencies do not have authority over tribal, commercial or recreational fishing; however, through increased abundance anticipated under the Preferred Alternative, more fish may be available for catch. Overtime, the Preferred Alternative is anticipated to benefit both wild and hatchery fish and the co-lead agencies continue to support information developed by the Hatchery Scientific Review Group and the Northwest Power and Conservation Council's Three-Step Review process. Regarding the Lower Snake River Compensation Plan (LSRCP), Bonneville directly funds the U.S. Fish and Wildlife Services annual operations and maintenance of the LSRCP. Congress authorized the LSRCP as part of the Water Resources Development Act of 1976 (90 Stat. 2917) to offset fish and wildlife losses caused by construction and operation of the four lower Snake River dams. A major component of the authorized plan was the design and construction of fish hatcheries and satellite facilities. The LSRCP is administered through the USFWS. The LSRCP hatcheries and satellite facilities produce and release more than 19 million salmon, steelhead and rainbow trout each year as part of the programs mitigation responsibility. Upon the breaching of the lower Snake River dams as analyzed in MO3, Bonneville would no longer have an obligation to fund US Fish and Wildlife Service for the operations and maintenance of the LSRCP facilities. Bonneville's funding authority is directly tied to the operation of the LSR dams. The co-lead agencies also recognize that there would be transitional needs that would be addressed in the additional mitigation measures for MO3 discussed in Chapter 5. The co-lead agencies, note as well that there are other hatcheries in the Snake River basin that would continue to produce fish not tied to LSRCP. Bonneville would continue to fund the LSRCP under all of the other alternatives, including the Preferred Alternative.
