3970	51	Shelley Silbert	Great Old Broads for Wilderness	The dams' structures themselves add to the taxpayer burden of keeping the lower Snake dammed, rendering the above-noted routine effort even more ridiculous. By 2030, if still in place, nine lower Snake dam turbines will be 60 years of age, and twelve others will be 50-60 years of age. As reflected in Graph Q below, the Corps of Engineers has projected the design-life of each turbine at 35-45 years. In other words, all of these turbines need to be rehabbed. At what cost? In its FY2016-2030 Hydro Asset Strategy for Large Capital Forecast, BPA is budgeting approximately $42 million per turbine for rehabbing 14 turbines at the McNary Dam on the Columbia River. This same Capital Forecast includes $2.8-$3 million per year for "turbine reliability" at Little Goose, Lower Granite, Lower Monumental, and Ice Harbor dams on the lower Snake. Projected out, the estimated cost of an after-2030 rehab of 21 lower Snake dam turbines exceeds $1 billion. Realistically, current and projected power market conditions make it highly improbable that money will ... or ever should ... be spent to rehab the lower Snake dam turbines. In an inappropriately timed March 30,2020, publicly released email (prior to the April 13th public comment deadline), BPA appeared to attempt to preempt public commenters' input. In the release, BPA stated, "...powertrain replacements for the Snake River Dam hydroelectric assets are not currently forecasted to occur within our 20-year system asset plan." "Currently" seems a sly word, for BPA's management plan is altered at BPA's will, depending upon age and status of assets, like turbines. At Ice Harbor, BPA has already replaced one turbine, is installing a second, and has a third on order. Why? The aged turbines need replacement. Turbines in all four Snake River dams will need to be replaced within a much shorter time than BPA's stated "49-60 years." As stated above, the Corps has projected turbine design-life at 35-45 years. In not stating this fact, BPA's publicly released statement is at best an example of misinformation. [graph included in document Lower Snake River Dams]	Turbine replacement is critical to ensure a continuous supply of renewable energy. The installation of Improved Fish Passage Turbines at Snake and Columbia River projects would increase fish survival while continuing this important source of energy. At Ice Harbor Dam, the first turbine installation is complete and the second is underway. Initial testing of this turbine supported early modeling that showed significant improvements in the turbine environment that would lead to important increases in survival of juvenile salmon and steelhead. These results show survival rates of over 98 percent. The continued installation and use of these turbines could assist in salmon recovery while supplying energy for the northwest. Additionally, the four lower Snake River dams are among Bonneville's lowest cost resources. Although the turbines at the four lower Snake River dams are between 41 and 50 years old and nearing their design lives, there are no plans for any immediate replacements. Investment decisions are driven by equipment condition, probability and consequence of failure and, as such, it is common for equipment to be in service well past its design life. For example, some turbine runners at McNary dam will be over 70 years old by the time the replacement project is complete. Long-term planning analyses that calculate the optimal economic time to replace equipment based on current and expected equipment condition, probability of failure and outage consequence, point to the late 2030s as the earliest replacement dates for major powertrain equipment at the four lower Snake River dams. Most turbine replacements are forecasted between the 2040s and 2060s which would put the turbines at the four lower Snake River dams at about the same age at replacement as McNary.
3979	1	N/A	N/A	Flexible spill is the centerpiece of the EISs Preferred Alternative. Applicable science does show increased levels of spill can help fish migration and provide some additional time for more effective actions. However, increased spills alone simply do not support a long-term fish survival strategy, and certainly do not provide a recovery strategy. In fact, parties to the current, short-term Flexible Spill Agreement have made this explicit and respected regional scientists confirm that flexible spill included in the Preferred Alternative will not deliver salmon the survival benefits they need.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of the National Marine Fisheries Service (NMFS) and the US Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. In regards to the comment on spill, the 2019-2021 Spill Operation Agreement was a short-term agreement that was intended to last until the Record of Decision for the CRSO EIS was signed. However, the fact that it was a short-term agreement did not preclude the co-lead agencies from considering the operation as a measure to include in the EIS. In fact, this operation had broad regional support, and would provide a high potential benefit to salmon and steelhead through increased spill while avoiding many of the adverse impacts to power generation and reliability associated with Multiple Objective alternative 4. This measure also would allow the co-lead agencies to gather important scientific information on the relationship between the CRS and latent mortality. This measure will be managed adaptively, through the established Regional Forum processes, to address unexpected challenges, such as potential delays to adult migration, effects to navigation, and other challenges or opportunities that may require either a temporary or permanent change. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
3979	2	N/A	N/A	After considerable study, the Northwest Power and Conservation Council established regional smolt to adult spawning return goals of 4% (on average) for recovery of the endangered fish populations, but none of the EISs alternatives achieve that goal except for dam removal.Warming temperatures as a result of changing climate will further erode any benefits of flexible spill as a long-term approach and underscore the urgent need for comprehensive and meaningful action. If the approach recommended by the EIS is adopted as a long-term strategy, recovery of salmon and steelhead is not viable. All indications are that extinction becomes nearly certain for them as well as the many rural communities whose economies rely on sport fishing on the Snake and Salmon Rivers.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. The 4% average Smolt-to-Adult return rate (SARs) target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the fish analysis in Section 7.7.4 the Preferred Alternative will make a substantial contribution to improving Snake River anadromous fish runs, but broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and would average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
3979	3	N/A	N/A	Add to this, that BPA has virtually exhausted its cash reserves, faces major repair/replacement costs for most of the turbines on the Lower Snake River, and is confronted with a dramatically changing Northwest energy market that will only get more competitive as more alternative clean energy sources come on line. BPA must significantly change its operations and divest itself of money losing assets like the Lower Snake River dams if it is to survive and provide reliable power at competitive rates. (See, Bonneville Power Administration and the Lower Snake River Dams: The Folly of Conventional Wisdom, June, 2018, by Jones & Laughy; also ttp://www.rmecon.co/RME%20Response%20to%20BPA%2020200330%20eMail.pdf), Yet, the Preferred Alternative fails to effectively address any of this.	Bonneville has high investment grade credit ratings from all three rating agencies who rate Bonneville's ability to pay its debt obligations over many years. These ratings factor for revenue producing assets, market dynamics, financial metrics including cash reserves and future capital needs among other things. In light of all factors, Bonneville has a very strong investment grade credit. As described in the Draft EIS, Section 3.7.2.5, on pages 3-801-802; and, Section 3.7.3.1, on pages 3-842-843, upward rate pressure is an important factor in the competitiveness of Bonneville's rates. The EIS describes the upward rate pressure caused by each of the Multiple Objective alternatives (MOs), the largest range of which is associated with the breaching of the four lower Snake River dams in MO3. The analysis includes assumptions about future operations and maintenance (O&M) and capital investment in the four lower Snake River dams. See Section 3.7.3.5, Table 3-166 in the Draft EIS. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 in the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170, in the Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review (see Footnote 1 below), the Headwater/Lower Snake Asset Class (see Footnote 2 below) is forecast to have a 50-year levelized cost of generation (see Footnote 3 below) of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. Footnotes: 1. The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2. In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3. Levelized Cost of Generation is defined as the forecasted direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Under the Preferred Alternative the Bonneville wholesale power rate pressure is estimated to be 2.7 percent relative to the No Action Alternative. A portion of that rate pressure has already been incorporated into the BP-20 wholesale power rates; and, the remaining rate pressure likely falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control.
3993	1	N/A	N/A	Enhanced fish ladders and increased spill can solve the problem with hardly any disruption of power generation, irrigation availability, and recreational opportunities	The CRSO EIS evaluated improvements to fish ladders and increased levels and timing of spill in the Multiple Objective alternatives. The four lower Snake River and four lower Columbia River dams have fish ladders that safely and effectively pass millions of adult salmon upstream. Adult upstream passage success through these dams is relatively high, generally around 90% from Bonneville to Lower Granite dam. In addition to passing up to 60,000 salmon per day, some of these dams may pass upwards of 250,000 shad in a single day. As described in Section 7.6.2, the Preferred Alternatives includes the Bonneville Ladder Serpentine Weir Modification measure that is expected to reduce stress and delay for adult salmon, steelhead and bull trout and has the potential to increase adult salmon and steelhead survival by reducing upstream passage time at the dam. The Preferred Alternative provides a balance of resource benefits and effects with a flexible spill regime. The Preferred Alternative would be implemented using a robust monitoring plan to help evaluate the effectiveness of the spill program. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
3994	1	bsmathers@idahofb.org	N/A	Without the Snake River Dams, farmers would no longer have economical transportation to get crops to the coast and this will put many of them out of business. Crops would have to be transported by truck which would result in substantial cost and damage to our highways, not to mention the congestion that would result, thus creating safety hazards for other drivers.	The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted. The EIS recognizes that there is no guarantee wheat grown in the Northwest would be competitive now or in the future because there are many factors that influence international commodity markets (e.g., trade agreements, the U.S. dollar, global supply, etc.). However, the analysis finds that the cost to transport wheat to market would continue to be lower than costs paid by other wheat growers in the United States (e.g., the Dakotas and Midwest). Favorable conditions for Northwest wheat growers that help them stay competitive are: (1) the natural environment of the Palouse region (weather, soils) is ideal for growing this type of wheat, which leads to some of the highest yields per acre in the world, and (2) proximity of Northwest export ports. Currently, the cost to transport wheat to market is quite low relative to other parts of the United States and world. Environmental and human health impacts associated with increased emissions of shipping goods by rail or truck are evaluated and described in the Section 3.8 Air Quality, and increased health and safety concerns due to increased truck traffic on roadways and potential for increased accidents are described in the Navigation and Transportation Section for other social effects (Section 3.10.3.5).
3994	2	bsmathers@idahofb.org	N/A	There is low hanging fruit that should be looked at first but is hardly being talked about. First, Avian depredation of smolts travelling down the river is catastrophic. In fact, I have read in several reports that avian depredation is equivalent to all other forms of death loss combined for smolts traveling down the Columbia.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. According to the avian management plan, the group is encouraging birds to nest in alternate locations outside of the Columbia River Basin. In addition, water management actions (Predator Disruption Operations measure) in the John Day reservoir is expected to further reduce avian predation on migrating juvenile fish.
3994	3	bsmathers@idahofb.org	N/A	Sea lions are eating and maiming a high percentage of adult salmon returning to spawn (possibly 30 to 40 percent or more). These sea lions are not endangered and are not native to the Columbia River system. They started turning up in the 1980s and are now numbering in the thousands in the lower Columbia River. I would ask that fish depredation by birds and seal lions be given more attention in the final EIS.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. According to the avian management plan, the group is encouraging birds to nest in alternate locations outside of the Columbia River Basin. In addition, water management actions (Predator Disruption Operations measure) in the John Day reservoir is expected to further reduce avian predation on migrating juvenile fish.
3994	4	bsmathers@idahofb.org	N/A	Taking care of salmon and steelhead depredation would have no negative impact on the regional economy and would pay dividends toward restoring healthy salmon and steelhead runs. There are also innovations to move fish up and down the river that should be looked at in the final EIS like Whooshh Innovations.	The four lower Snake River and four lower Columbia River dams have fish ladders that safely and effectively pass millions of adult salmon upstream. Adult upstream passage success through these dams is relatively high, generally around 90% from Bonneville to Lower Granite dam. In addition to passing up to 60,000 salmon per day, some of these dams may pass upwards of 250,000 shad in a single day. The technology of fish cannons or similar devices has demonstrated some success on smaller scales, and their use will continue to be evaluated for future applications.
3999	1	ttrue@earthjustice.org	Earthjustice	The socioeconomic elements of the DEIS fail to address or employ widely accepted professional standards applicable to ensure a thorough, objective and transparent evaluation of the alternatives considered in the DEIS. These standards are expressed jointly in court interpretations of the National Environmental Policy Act (NEPA), the Corps guidance documents for socioeconomic analyses, the Principles, Requirements, and Guidelines for Federal Investments in Water Resources (PR&G) developed in response to the requirements of the Water Resources Development Act of 2007 (WRDA), the Department of Interiors Agency Specific Procedures for implementing the Principles, Requirements, and Guidelines, Executive Order 12866 Regulatory Planning and Review, and the Office of Management and Budgets Circular A-4. These deficiencies result in deep, systemic gaps in the socioeconomic elements of the DEIS, so that the document: A. Does not use all the available socioeconomic information that is relevant, accurate, and reliable.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish a framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. Regarding the PR&G requirements, if an agency is seeking authorization and appropriations from Congress to fund a federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. One of the goals of a PR&G analysis is to determine the economically justified alternative by conducting an economic cost benefit analysis, referred to as National Economic Development (NED) effects in the superseded P&Gs. In the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. CEQ NEPA regulations (40 CFR 1502.23) address the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. Further there is no policy or law that requires the use of the PR&Gs.
3999	2	ttrue@earthjustice.org	Earthjustice	B. Does not make a substantial, objective effort at studying, analyzing, and evaluating, all the socioeconomic issues relevant to the actions considered insofar as it does not: Use all the available socioeconomic information that is relevant, accurate, and reliable Account fully for the socioeconomic importance of ecosystems and ecological risks Consider equally both effects that are monetized and effects that are not Take a hard look at all the socioeconomic consequences of the Preferred Alternative and other alternatives	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate sections of the FEIS (for example, in water quality, water supply, air quality, recreation, etc.). As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. As described in Chapter 7 of the Final EIS, the Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Under the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. CEQ's NEPA regulations (40 CFR 1502.23) address the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations.
3999	3	ttrue@earthjustice.org	Earthjustice	C. Does not fully disclose all relevant information, and provide full transparency to the decision-making process, to enable the public or decision-makers to understand the rationale for selecting the Preferred Alternative.	The co-lead agencies used a multi-disciplinary and science-based approach to analyze the alternatives in the EIS analysis. The co-lead agencies invited a number of entities, including Tribes, states, and local agencies, from across the region to participate in the EIS process as cooperating agencies, and more than 30 of those invited agreed to participate. Staff from the cooperating agencies joined the technical teams and provided their expertise and review to the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation and configuration of the dams in the Columbia River System. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The draft EIS was subjected to two internal agency reviews by Corps' reviewers not involved in the development of the document. Then the document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process. The final IEPR report will be publicly available. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. As required by the National Environmental Policy Act (NEPA), the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapters 3, 4, 5, 6 and 7; summarized by resource and alternative in Table 3-1, and presented for comparison in Tables 7-1 and 7-55 in the Draft EIS. Effects specific to anadromous fish are described in Sections 3.5.3 and 7.7.4. In the Draft EIS, Table 3-61 compares expected survival by alternatives, and Table 3-62 provides a comparison of the alternatives specific to anadromous fish. A robust analysis and fulll disclosure of the anticipated effects of all evaluated alternatives against the No Action Alternative has informed the public of the potential effects of the actions, as well as informed the decision makers of the potential adverse effects of any action that may be recommended.
3999	4	ttrue@earthjustice.org	Earthjustice	D. Does not describe the extent to which the Preferred Alternative, relative to other alternatives, will promote realization of the Federal Objective for water and land-related resources, as expressed in WRDA including: Maximizing sustainable economic development Avoiding the unwise use of floodplains and flood-prone areas Protecting and restoring the natural functions of natural systems E. Does not demonstrate that the Preferred Alternative will accomplish the Federal Objective, by maximizing the public benefits derived from the nations water and land-related resources.	The EIS evaluates the on-going operations, configuration, and maintenance of the 14 projects that make up the Columbia River System. Each alternative was evaluated for how changes in operations could reduce or eliminate adverse effects, while meeting EIS objectives and the Purpose and Need Statement. The Purpose and Need Statement includes both the federal objectives of each project, otherwise known as "authorized purposes", that came from previous WRDAs and Flood Control Acts, as well as statutory and legal commitments. The comparison of each alternative in meeting these federal purposes is in Chapter 7, Table 7-1. Chapter 3 includes discussion of any changes to floodplains, economies, and the natural environment. Summaries of the changes are in Chapter 7, Table 7-2. These 14 projects are ongoing projects, and not a new feasibility study. With the exception of MO3, implementing any of the alternatives proposed would not require WRDA authorization. However, as noted in the EIS, if M03 were recommended as the Preferred Alternative, it would require congressional authorization through WRDA or another authorization bill. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids, resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is most likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
3999	5	ttrue@earthjustice.org	Earthjustice	II. Socioeconomic Elements of the DEIS Fail to Satisfy Standards of Completeness and Objectivity Established by NEPA The requirements for a complete and objective analysis in environmental impact statements have evolved in response to recognition that, in the past, the activities of action agencies often were shaped by consideration of factors not relevant to a thorough analysis of the environmental consequences of a proposed action and its effects on the overall socioeconomic well-being of the American public. This negative effect on the American public as a whole came about as action agencies looked selectively at data and other information to justify decisions that produced benefits for the agencies, themselvese.g., increases in the amount of money they spend, job security, and political influenceand for their client industries. The relevant requirements for a complete and objective analysis thus aim to ensure that, when agencies develop resource-management actions/plans, they pursue the goal of producing maximum benefits for the public at large, with due consideration for the associated costs, and perform a complete, objective, and transparent analysis focused on the effects of the proposed action and a range of alternatives. In this case, though, the socioeconomic elements of the DEIS step back in time and disregard careful,	The co-lead agencies provided a robust analysis of socioeconomic effects in the EIS. As required by NEPA, the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapters 3, 4, 5, 6 and 7; summarized by resource and alternative in Table 3-1, and once again presented for comparison in Table 7-1. Socioeconomic analysis are discussed under numerous resources: Power Generation and Transmission; Air Quality and Green House Gasses; Navigation and Transportation; Recreation; Water Supply; Fisheries and Passive Use; Environmental Justice; and Implementation and System Cost Analysis. The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate section of the Final EIS (for example, in water quality, water supply, air quality, recreation, etc.). The EIS also acknowledges the cumulative impacts to affected resources in Chapter 6 for the No Action Alternative as well as Multiple Objective alternative 1, Multiple Objective alternative 2, Multiple Objective alternative 3, and Multiple Objective alternative 4 and Chapter 7 for the Preferred Alternative as well as the climate effects in Chapters 4 and 7.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				thorough, and objective application of these requirements. These primary and overlapping deficiencies include the failure to satisfy the standards and requirements for an adequate EIS established by the National Environmental Policy Act (NEPA). The National Environmental Policy Act (NEPA) sets the stage for defining the analytical standards the co-lead agencies must meet in developing an environmental impact statement (EIS) for the CRSO EIS and the alternatives it considers. NEPA states that federal agencies "to the fullest extent possible" must provide a detailed EIS.1 In applying this standard, courts have held that, at a minimum, NEPA imposes on an agency a duty to take a "hard look at environmental consequences" and a requirement of a substantial, good faith effort at studying, analyzing, and expressing the environmental issues in the EIS and the decisionmaking process.2 A sufficient EIS must provide good faith analysis and sufficient information to allow a firm basis for weighing the risks and benefits of a proposed action.3 A large gulf exists between the DEIS and these standards. For example: 1. The DEIS contains no consolidated, detailed, and comprehensive description of the socioeconomic costs, benefits, and impacts of the alternatives it considers on the regional economy As a result, it is impossible for the public or a decision-maker to determine, from reading the DEIS, the actual and full socioeconomic impacts of each alternative, the details of individual socioeconomic impacts on relevant socioeconomic issues for each alternative, or the relative socioeconomic impacts of the Preferred Alternative relative to other alternatives.	
3999	6	ttrue@earthjustice.org	Earthjustice	This example, from CHAPTER 6 CUMULATIVE EFFECTS, illustrates the agencies failure. The DEIS states: In general, relevant past cumulative actions that have affected aquatic species and other wildlife include construction and operation of dams, levees, and other river infrastructure; dredging and sediment 1 42 U.S.C. 4332. 2 Natural Resources Defense Council v. Morton, 458 F.2d 827, 838 (D.C. Cir., 1972) 3 County of Suffolk v. Secretary of the Interior, 562 F.2d 1368 (2nd Cir. 1977), cert. denied, 434 U.S. 1064 (1978) Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 3 management; commercial and recreational fishing harvest; invasive species; floodplain development; water pollution; logging and mining; water withdrawals to support human development; and agricultural, urban, and transportation corridor development. Relevant past cumulative actions also include the voluntary actions and Federal- and state-mandated actions of private and public parties to create positive and offsetting effects for affected aquatic species and other wildlife. These include but are not limited to hatcheries and fisheries management; predation management; hydro operations and asset management; water quality management; and habitat, conservation, and land management. This statement includes no socioeconomic variables or relevant information, let alone detailed information, to evaluate the socioeconomic context in which the alternatives considered would be implemented. Thus, it excludes, for example, reference to trends that see many households placing greater value on actions that would yield increases (or diminish decreases) in salmon populations. It excludes changes in population that reflect the availability of natural resource amenities (more robust growth in population and household income for areas with more amenities). Moreover, it excludes recognition that public preferences matter. Thus, the agencies, themselves, determine what is and is not a positive effect, without describing or attempting to analyze available information about the publics preferences for increased numbers of fish that reproduce in the ecosystem, rather than for hydro operations. And the agencies never explain their failure to explain the socioeconomic value the public places on this and other tradeoffs. They simply do not acknowledge or address the strong and well-documented public preferences for increases in ecosystem health, and for abundant and resilient populations of orcas, and for ecosystem-reproduced salmon and steelhead. The agencies never analyze the socioeconomic importance of the alternatives effects of these and other variables.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate section of the EIS (for example, in water quality, water supply, air quality, recreation, etc.). As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies' numerous legal obligations. As described in Chapter 7 of the Final EIS, the Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Finally, the EIS describes the multiple different ways that people may hold value for salmon and other natural resources, including non-use (i.e., "passive use") values that are not associated with direct experience (e.g., fishing, subsistence). As described in this comment, the EIS (Section 3.15.2.2) summarizes the existing literature on passive use values for salmon and affirms that the literature demonstrates that the general public holds value for the salmon and that the population that may benefit from increased salmon populations may be geographically far-reaching. However, due to limitations in the literature and uncertainty regarding the changes in overall fish abundance predicted under each alternative (as different fish are affected positively and adversely), the EIS does not rely on this literature to estimate a monetary value of the effects on fish. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision making, including the effects of the alternatives on fish as detailed in Sections 3.5 and 7.7.4. That the effects of the alternatives on passive use for fish are not expressed quantitatively (e.g., monetized economic values) does not mean that they were not considered in the context of the analysis. While Section 6.3.1.15 is titled "Fisheries and Passive Use," Table 6-40 in the draft EIS is described as "Reasonably Foreseeable Future Actions Relevant to Fisheries." As with commercial, subsistence, and ceremonial fishing, passive use values for fish are tied to cumulative actions that affect fish abundance. These actions are described in Tables 6-19 and 6-21 in the draft EIS.
3999	7	ttrue@earthjustice.org	Earthjustice	In Section 6.3.1.1 Hydrology and Hydraulics, the agencies further demonstrate their failure to address the socioeconomic issues and data on public preferences. In this section, the agencies speak about demand for consumptive water uses, energy development, and storage without recognition that prices play a role in determining and expressing the true, economic demand. If the prices for these goods go up, then the economic demand would go down, and vice versa, but the agencies never provide any analysis telling readers which to expect, and why. Thus, their use of the term, demand, is more a casual observation than any analysis of data, and it has little analytic meaning. Reinforcement for this conclusion comes from the agencies parallel failure to carefully examine the tradeoffsfor fish, ecosystem health, orcas, and other resourcesthat accompany the provision of consumptive water uses, energy development, and storage. These tradeoffs, and the publics preferences for the opposing outcomes, influence the true, economic demand. If preferences for fish go up, the true demand for consumptive water uses, energy development, and storage would go down, and vice versa, but the agencies never provide any analysis telling readers which to expect, and why. Moreover, the agencies never even attempt to provide a careful and complete description of how the realities of prices and tradeoffs will interact with the different CRSO alternatives to provide the public with different mixes of goods and services. In this section and others, the disregard for economic principles, and for the available socioeconomic data and tools for analyzing them, indicates that the agencies have failed to apply relevant expertise to their analysis in the DEIS.	The EIS applies economic principles and acknowledges the relationship of price and demand, including the elasticity of demand (i.e., how increasing prices may decrease demand, consistent with the statement in the comment). The power analysis applied elasticities in the retail rate analysis to assess regional economic effects. Specifically, the power analysis describes how increasing retail rates may decrease demand for electricity and applies these elasticities to the estimated demand of residential, commercial and industrial electricity consumers in the region (e.g., see Section 3.7.3.3 for the discussion of these effects on regional households under MO1). Section 5.2.2. Expenditure Analysis, of Appendix H, Power and Transmission, provides additional discussion on the demand for electricity and elasticities, including the specific elasticity estimates applied in the power socioeconomic analysis.
3999	8	ttrue@earthjustice.org	Earthjustice	The disregard for socioeconomic realities also appears in this sections description (p. 6-20) of the No Action Alternative, when it states: There could be substantial effects to hydraulics and hydrology (changes from existing condition) under the No Action Alternative from cumulative actions such as climate change. However, the contribution of the No Action Alternative to these combined cumulative effects would be negligible on its own, because the No Action Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 4 Alternative operations do not appreciably change the hydrology and hydraulics in the Columbia River Basin from the existing conditions as described in Chapter 3. In an engineers eyes, it may be correct that the No Action Alternative will not appreciably change the hydrology and hydraulics in the Columbia River Basin, but the statement makes no sense from a socioeconomic perspective.4 No change in the physical characteristics of the Basin does not necessarily mean that continued operation of the existing infrastructure and programs will have no effect on the value of the goods and servicesincluding ecosystem servicesthe American public derives from these rivers and their ecosystems. Insofar as continued operation means, for example, that high levels of risk for at-risk species and for the overall health of ecosystems will persist and intensify, the No Action Alternative will absolutely have more than a negligible effect on the value of the ecosystem services associated with hydrology and hydraulics.5	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate section of the EIS (for example, in water quality, water supply, air quality, recreation, etc.). As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies' numerous legal obligations. As described in Chapter 7 of the Final EIS, The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The CRSO EIS appropriately evaluates the impacts to affected resources under the No Action Alternative and the Multiple Objective Alternatives, including the Preferred Alternative.
3999	9	ttrue@earthjustice.org	Earthjustice	Nowhere does the DEIS provide the public or decision-makers with the information they need to understand the significance of these potential changes in value, or to compare the changes under the No Action Alternative against the potential changes in value that might occur under other alternatives. Similarly, in Section 6.3.1.2 River Mechanics, the agencies ignore the socioeconomic importance of ecosystem services, when they state: The effects from dam breaching would be major and would be the largest influence on sediment process effects. [bold highlight added] This statement does not identify or explain the metrics the agencies used to determine what constitutes a major effect and by how much. Nowhere in this section does the DEIS incorporate socioeconomic concerns into its assessment of these effects. If, for example, the changes in sediment process from breaching were to have no effects on the value of goods and services derived from the sediment, would the agencies still consider the effects to be major? What changes in the value of goods and services constitute the boundary between major and minor effects? Between minor and insignificant?	As required by NEPA, the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapters 3, 4, 5, 6 and 7; summarized by resource and alternative in Table 3-1, and once again presented for comparison in Tables 7-1 and 7-55. The effects determinations are described in Section 3.1. and are summarized as follows: No Effect: The action would result in no effect as compared to the No Action Alternative. Negligible Effect: The effect would not change the resource character in a perceptible way. Negligible is defined as of such little consequences as to not require additional consideration or mitigation. Minor Effect: The effect to the resource would be perceptible; however, it may result in a small overall change in resource character. Moderate Effect: The effect to the resource would be perceptible and may result in an overall change in resource character. Major Effect: The effect to the resource would likely result in a large overall change in resource character. Additionally, the co-lead agencies used current, high quality information and best science in the analysis of the CRSO EIS. Quantitative evaluations were conducted to determine the effects of each of the alternatives when appropriate. In instances where quantitative evaluations were not appropriate or possible, qualitative discussions are included to describe the effects of each alternative. The evaluations are clear, transparent, and repeatable based on high quality information. The rationale for why an impact is considered to fall under one of the intensity descriptors is included Section 3.1 and in each resource section in Chapter 3. The Alternative Comparison Thresholds subsection of Section 3.3.3.1, Analysis Metrics, provides a further summary of the impact assessment thresholds used for the River Mechanics assessment. The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate sections of the Final EIS (for example, in water quality, water supply, air quality, recreation, etc.). As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making.
3999	10	ttrue@earthjustice.org	Earthjustice	The agencies compound their failure to consider socioeconomic variables and relationships in Table 6-19 Reasonably Foreseeable Future Actions Relevant to Anadromous Fish. They explain that the table provides a summary of the effects of these actions. Nowhere in this table, however, do the agencies describe foreseeable changes in the value the public, or specific groups, place on anadromous fish. Thus, the table states that Increase in Demand for New Water Storage Projects is a reasonably foreseeable future action that would have potential for 4 Note that the bio-physical assessment description of the No Action Alternatives conflicts with the facts. Evidence presented in Appendix V Biological Assessmente.g., the adjacent text and information in Tables 3-10, 3-18, 3-26, 3- 32, 3-34, and 3-41concede that the existing CRSO has on-going negative effects on anadromous fish. 5 The response to the COVID-19 outbreak illustrates this point. Some governments apparently assumed that the risk of a pandemic would not materialize and, accordingly invested what has proven to be an inefficient amount in the testing capacity, protective equipment, etc. needed to anticipate, detect, and respond to it. By doing so, it appears that they also increased the likelihood that the emergence of the virus would turn into a pandemic. To the extent that, with No Action, the agencies do not consider and anticipate similar kinds of ecological risk, then they will not be adequate to respond such risks and will be more likely to contribute to a failure to address the risk and make any risk that materializes worse than it otherwise would be. Thus, the No Action alternative is not a benign baseline against which it is appropriate to measure the ability of other alternatives to resolve ecological problems. It is, instead, a contributor to those problems but this aspect of the No Action Alternative is nowhere described, discussed or disclosed and, consequently, the presentation of the other alternatives and whether they are robust to such risks is not addressed in the DEIS. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 5 adverse effects [on anadromous fish] from changes to timing, delivery, and quantity of water in	The EIS (Section 3.15.2.2) describes the existing literature on passive use values for salmon, including the studies referenced in this comment, and affirms that the literature demonstrates that the general public holds value for the salmon and that the population that may benefit from increased salmon populations may be geographically far-reaching. However, as is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does evaluate the cumulative effects to Fisheries and Passive Use in Sections 6.3.1.15 and 7.9.18, but as described above, this analysis focuses on the effects to Fisheries given the wide-ranging uncertainty in the literature on passive use values. Finally, the United States Federal Government supports the development of alternative forms of energy through many different programs and policies. For example, the Bonneville Power Administration also has a robust conservation program, from which about 90 aMW in conservation are saved a year. Further, when acquiring long-term resources, the Bonneville Power Administration statutory directives give priority to conservation and renewable resources. The analysis for MO3 demonstrates what types of resources would be needed to replace the key attributes of the four lower Snake River dams. Included in this analysis is a resource portfolio made up of alternative forms of energy (i.e., wind, solar, and batteries). As described in Section 3.7, and Chapter 7,the adverse reliability and upward rate pressure impacts from breaching the four lower Snake River dams support retaining these resources over other alternative forms of energy.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				different locations from new storage projects. Nowhere, however, does the table identify that an increase in the demand for higher fish populations, or for a free-flowing river, or for a reduction in overall risk to the ecosystem would have potential for positive effects on fish. Similarly, the table states that New and Alternative Energy Development is a reasonably foreseeable future action that would have a possible adverse effect from increase in lack-ofmarket or lack-of-turbine-capacity spill in the future and higher TDG levels if shifting away from hydropower to other sources occurs, but no recognition that such development could have a positive effect by showing consumers that they dont need to depend on hydropower from the Lower Snake River dams and, hence, they increase their preference for modifying the CRSO to yield higher fish populations. The agencies failure to recognize in Table 6-19 the socioeconomic issues and their potentially positive implications for anadromous fish does more than demonstrate an important vacancy in its identification of important potential effects from the CRSO, it also lays the foundation for the agencies subsequent failure to apply the relevant expertise to analyze these effects and their interactions with the different alternatives.	
3999	11	ttrue@earthjustice.org	Earthjustice	In the discussion of cumulative effects for MULTIPLE OBJECTIVE ALTERNATIVE 3, the agencies say there would be minor increases in juvenile survival and adult returns and fewer powerhouse encounters for upper Columbia River salmon and steelhead. Quite apart from the inaccuracy of this characterization, nowhere does the discussion describe the socioeconomic importance of minor increases or fewer powerhouse encounters. The discussion also says, The degree of cumulative benefits is uncertain, however, [as] there are other factors such as climate change (higher water temperatures, decreased in-river water flow, etc.) that could have adverse effects to anadromous species that outweigh benefits from measures in MO3 and other actions intended to benefit anadromous species. Nowhere does the text describe the socioeconomic importance of the uncertainty. How large are the cumulative benefits likely to be and what are the associated socioeconomic benefits? How big are the risks that things will go wrong? That is, what is the value of the ecosystem services that would be lost if the uncertainties manifested themselves as actual declines in populations of at-risk species? Also, nowhere does the text demonstrate that the agencies accounted for socioeconomic preferences and value when they concluded that the adverse effects would outweigh the benefits. From a socioeconomic perspective, these statements are meaningless and reveal only the agencies general and uninformed characterizations of some very limited aspects of the effects of the alternatives, characterizations that displace the hard look required by NEPA and fail to inform the public or decision-makers about the actual consequences of the choice among alternatives.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate section of the EIS (for example, in water quality, water supply, air quality, recreation, etc.). As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies' numerous legal obligations. As described in Chapter 7 of the Final EIS, the Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Finally, NEPA does not require the agencies to speculate on the effects of "worst-case" scenarios.
3999	12	ttrue@earthjustice.org	Earthjustice	In Section 6.3.1.8 Air Quality and Greenhouse Gases, the agencies state that their analysis identifies increased power generation from fossil fuels, including both coal and natural gas, even under the zero-carbon resource replacement portfolio, degrading air quality and increasing GHG emissions. Two sentences later, they indicate that their analysis reflects their assessment that, Based on currently available technology, other renewable resources (e.g., solar and wind) are intermittent [bold highlight added] This statement indicates that the agencies paid no attention to the socioeconomic forces and trends associated with these renewable technologies and, hence, failed to acknowledge that the prices of these technologies have been falling and probably will continue to fall rapidly. Falling prices means that these technologies will increasingly have economic incentives to find ways to overcome the intermittent character of the technology and, hence, to become competitive with, i.e., cheaper than, fossil-fuel electricity. Indeed, the falling prices indicate fossil-fuel generators may actually be unlikely to replace declines in hydropower from the CRSO. This is an especially critical omission, since the DEISs analysis of energy and other factors, albeit limited and incomplete, speaks of time lines that range from 25 to 50 years. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 6 Basing a discussion of these issues over this time horizon on currently available technology when information about future trends is readily available is not just short-sighted, it is inaccurate and misleading. In other words, the failure to integrate socioeconomics into the analysis using readily available tools and information renders the agencies analysis meaningless or worse.	The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements would likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council (Council) in their Seventh Power Plan (Seventh Power Plan page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. The use of storage technologies is considered a long-term resource in the Seventh Power Plan, but has become more commercially available since the release of the Seventh Power Plan, will be considered a primary resource in the Councils Eighth Power Plan, and is examined in the EIS. To address concerns about potential reductions in resource costs, publicly released draft information, such as updated prices for solar and battery storage, from development of the Eighth Power Plan is included as rate sensitivities in the Final EIS. The Final EIS also includes the de-escalating cost curves prepared by the National Renewable Energy Laboratory (NREL) that will be used by the Council in the 8th Power Plan. See Final EIS Section 3.7.3.1
3999	13	ttrue@earthjustice.org	Earthjustice	In Section 6.3.1.15 Fisheries and Passive Use, the agencies show information (Table 6-40) describing reasonably foreseeable future actions relevant to fisheries. [bold highlight added] This section does not, however, include an analogous table showing information describing reasonably foreseeable future actions relevant to passive use. This failure deprives the public and decision-makers, for example, from research findings that indicate: o Valuing societal impacts from changes in salmon proceeds from recognizing various pathways of human benefit. Some benefits are relatively obvious, such as resource use and extraction in the market economy, e.g., commercial fish harvest, and revenue from fishing-related expenditures. A less recognized but important dimension are nonmarket benefits, such as the recreational enjoyment of a fishing experience. An angler may contribute only minimally to a local economy through the act of fishingyet the opportunity to engage in this pastime may be of extraordinarily high value to that individual. Yet human appreciation of natural resources such as salmon goes deeper still. For decades environmental economists have recognized an important category of benefits known as non-use values. Essentially, resources may be valued without the necessity of direct experience. Notions of value predicated on resource extraction, harvest, and even nonconsumptive recreational use are overly limiting. Categorically neglecting non-use values can lead to significant underestimates of public welfare. Salmon recovery within a relatively small watershed has been found to be valuable to households across the nation. [S]tudies consistently indicate that households in the Pacific Northwest and beyond have a high WTP [willingness to pay] for increased salmon.6 [citations omitted] This summary of relevant literature make clear that, because the agencies failed to consider the passive-use values of resources affected by the CRSO, it is reasonable to conclude that the DEIS probably significantly underestimated the public benefits from actions that would restore the Lower Snake to a free-flowing river; increase the populations of salmon, steelhead, orcas, and other at-risk species; and increase the area of healthy wildlife habitat. The agencies treatment, in Chapter 3, of research on passive use provides additional support for this conclusion (see further discussion of this issue, below).	The EIS describes the multiple different ways that people may hold value for salmon and other natural resources, including non-use (i.e., "passive use") values that are not associated with direct experience (e.g., fishing, subsistence). As described in this comment, the EIS (Section 3.15.2.2) summarizes the existing literature on passive use values for salmon and affirms that the literature demonstrates that the general public holds value for the salmon and that the population that may benefit from increased salmon populations may be geographically far-reaching. However, due to limitations in the literature and uncertainty regarding the changes in overall fish abundance predicted under each alternative (as different fish are affected positively and adversely), the EIS does not rely on this literature to estimate a monetary value of the effects on fish. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision making, including the effects of the alternatives on fish as detailed in Sections 3.5 and 7.7.4. That the effects of the alternatives on passive use for fish are not expressed quantitatively (e.g., monetized economic values) does not mean that they were not considered in the context of the analysis. It is correct that, while Section 6.3.1.15 is titled "Fisheries and Passive Use," Table 6-40 in the Draft EIS is described as "Reasonably Foreseeable Future Actions Relevant to Fisheries." As with commercial, subsistence, and ceremonial fishing, passive use values for fish are tied to cumulative actions that affect fish abundance. These actions are described in Tables 6-19 and 6-21 in the Draft EIS.
3999	14	ttrue@earthjustice.org	Earthjustice	o [T]he Total Economic Value [use value plus non-use value] for a species is likely to be underestimated when respondents feel that the population of the species is at a reasonably secure level. [Threatened and endangered (T&E)] species provide considerable benefits and have great value, pointing to the need for greater funding and more preventative measures in their recovery. Evidence from this study shows that people's valuation of T&E species has indeed increased over time.7 These findings suggest that it would be reasonable for the agencies to foresee future actions wherein Americans assign increasingly larger values to actions that promise 6 Weber, M.A. 2015. Navigating benefit transfer for salmon improvements in the Western US. 7 Richardson, L., and J. Loomis. 2008. The total economic value of threatened, endangered and rare species: an updated meta-analysis. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 7 to increases in salmon and steelhead populations. These larger values, which include both use value and non-use values (also known as passive-use values) likely will emerge if the public perceives an increase in the risk of extinction for salmon and steelhead, and in response to evidence indicating other species around the world are becoming increasingly threatened with extinction.	That scarcity influences the value people place on resources is a well-accepted economic principle. It pertains to threatened and endangered species, which are, by definition, at greater risk of extinction. This comment correctly highlights this point as does the summary of literature in Section 3.15 in the EIS on passive use values. Specifically, the literature identifies that people value recovery of ESA-listed species and increasing their abundance. However, the literature generally evaluates passive use benefits of large-scale population changes (including "restoring" salmon populations, "delisting" species, or doubling population sizes). Values people hold for such changes are not necessarily scalable for more marginal changes in population levels as are expected under the various alternatives in this EIS. The EIS is additionally consistent with this comment in describing that use (e.g., commercial and recreational fishing) values for salmon would increase with increased abundance.
3999	15	ttrue@earthjustice.org	Earthjustice	o The incremental passive use values for the increase in anadromous fish due to the dam breaching [on the Lower Snake River] is [sic] ranges from a high of $879 million for households in the Pacific Northwest and California to a low of $66 million with a middle range between $142 and $508 million. Also based on the existing literature there appears to be a passive use value of $420 million annually for returning the Lower Snake River to a free-flowing condition, independent of any effect on salmon populations.8 This statement demonstrates that, since at least 1999, economists have published estimates of the passive-use value the public would realize from increases in Snake River salmon populations on the Snake River and from restoring the free-flowing character of the Lower Snake River. Compounding the problem, in Table 6-41, the agencies purport to describe the social welfare effects and the regional economic effects of each alternatives impacts on fisheries, but they incorporate no socioeconomics in the text or in the underlying analysis. Thus, this table reinforces the conclusion that the agencies totally failed to conduct the careful, comprehensive analysis required to take a hard look at the socioeconomic impacts of the different alternatives for the CRSO.	The EIS provides an evaluation of the social welfare and regional economic effects of the alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). Additionally, the EIS (Section 3.15.2.2) describes the existing literature on passive use values for salmon and affirms that the literature demonstrates that the general public holds value for the salmon and that the population that may benefit from increased salmon populations may be geographically far-reaching. However, due to limitations in the literature and uncertainty regarding the changes in overall fish abundance predicted under each alternative (as different fish are affected positively and adversely), the EIS does not rely on this literature to estimate a monetary value of the effects on fish. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision making, including the effects of the alternatives on fish as detailed in Sections 3.5 and 7.7.4. That the effects of the alternatives on passive use for fish are not expressed quantitatively (e.g., monetized economic values) does not mean that they were not considered in the context of the analysis.
3999	16	ttrue@earthjustice.org	Earthjustice	2. The DEIS does not describe the costs and benefits that would accrue to the public from each alternative The DEIS focuses on describing the amounts of money the agencies would spend under each alternative. Thus, as the agencies sought to satisfy their duty to take a "hard look at the socioeconomic consequences of the alternatives they felt it necessary to detail the amounts of money they would spend under each alternative (and the DEIS devotes Appendix Q to this topic) but totally dismissed their obligation to let the public know what costsand benefits the public would experience. The co-lead agencies reveal their disregard for socioeconomic impacts accruing to the public, for example, in Section 5.2 DECISION FRAMEWORK AND SELECTION PROCESS, when they describe the criteria they used to select mitigation measures. The description for one of these criteria states: Feasibility: a qualitative assessment of the feasibility of implementing a measure based on technical and economic factors. For example, a mitigation measure may not be feasible if there are other technical actions that would effectively reduce the severity or duration of impact. Similarly, if the expense of implementing a measure would be unreasonable, then the measure would not be feasible. [bold highlight added] The highlighted sentence makes clear that the agencies fixed their concern on the expense they would incur to implement a given mitigation measure. This perspective ignores the potential external costs, monetized or not, that members of the public would incur from implementation of the measure. It also ignores the public benefits from the different potential mitigation measures and how these might affect a choice among available measures. Thus, it appears they would rank a measure with low financial costs above any measure with moderate or high financial costs, regardless of the size of the benefits to the public of any of the measures, and 8 Loomis, J. 1999. Passive use values of wild salmon and free-flowing rivers. Natural Resource Economics, Inc. Comments on	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses (see 40 CFR 1502.23), the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish a framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The EIS does evaluate the costs of the alternatives in Sections 3.19 and 7.7.21 as well as in Appendix Q. The EIS also evaluates Passive Use values in Sections 3.15 and 7.7.17. To further address concerns about potential reductions in resource costs, consistent with the comment, publicly released draft information, such as updated prices for solar and battery storage, from development of the Northwest Power and Conservation Council's Eighth Power Plan is included as rate sensitivities in the Final EIS. The Final EIS includes the de-escalating cost curves (declining future cost trends for renewables) prepared by the National Renewable Energy Laboratory that will likely be used by the Council in the Eighth Power Plan.

				Socioeconomic Elements of CRSO DEIS 8 even if these public benefits far outweighed the agencies additional financial costs. This illustration supports the conclusion that the agencies did not develop the DEIS and select the Preferred Alternative with the goal of producing the maximum net socioeconomic benefits for the American public, and they did not analyze or describe these benefits in a way that would enable the public or decision-makers to understand the effects of the choice among alternatives.	
3999	17	ttrue@earthjustice.org	Earthjustice	3. The DEIS does not describe the socioeconomic importance of changes in ecosystem services that would result from implementation of each alternative Ecosystem services are natures contributions to humans well-being. Extensive evidence indicates that the value of the services derived from ecosystems exceeds, often by a considerable amount, the value of goods and services produced by human activities, known as the gross domestic product.9 As a consequence, it is reasonable to conclude that the DEIS omits and disregards more than one-half of the potential socioeconomic impacts of the various alternatives. Particularly egregious is its failure to describe the increases in ecosystem services expected to materialize with the breaching of dams under the Multiple Objective 3 alternative, and the socioeconomic importance of those increases in services. Nowhere is there a chapter dedicated to defining and describing the ecosystem services derived from the ecosystemsindividually and in the aggregateaffected by the CRSO. Nowhere does the DEIS present a table, analogous to those that relate to the CRSs infrastructure, showing the reasonably foreseeable future actions that would affect the ecosystems ability to supply these ecosystem services or affect their socioeconomic value to the overall public or to different groups. The DEIS does not contain any description of the socioeconomic importance of the ecosystem services, individually or in the aggregate, or of how the several alternatives would affect these socioeconomic values. From reading the DEIS, no member of the public or decisionmaker can determine, even roughly, how the ecosystem services under the Multiple Objective 3 alternative comparein biophysical terms or socioeconomic valuewith those under the Preferred Alternative. The agencies and the DEIS ignore the socioeconomic importance of the improvements in ecosystem services that would occur with the Multiple Objective 3 alternative despite extensive, readily available evidence that shows the resulting improvements in ecosystem services would provide socioeconomic benefits that far outweigh the dam-removal costs.10 .9 A small selection of the relevant literature includes, for example: Li, G., and C. Fang. 2014. Global mapping and estimation of ecosystem services values and gross domestic product: a spatially explicit integration of national green GDP accounting; Costanza, R., et al. 2014. Changes in the global value of ecosystem services; Costanza, R. et al., 2017. Twenty years of ecosystem services: how far have we come and how far do we still need to go? Santos Gaspar, J., et al. 2017. The traditional energy-growth nexus: a comparison between sustainable growth and economic growth approaches; Hejnowicz, A.P. and M.A. Rudd. 2017. The value landscape in ecosystem services: value, value wherefore art thou value? Song, X-P. 2018. Global estimates of ecosystem service value and change: taking into account uncertainties in satellite-based land cover data; Intergovernmental Science-Policy Platform on Biodiversity and Ecosystem Services (IPBES). 2018. The IPBES regional assessment report on biodiversity and ecosystem services for the Americas; and Sannigrahi, S., et al. 2018. Estimating global ecosystem values and its response to land surface dynamics during 1995-2015. 10 See, for example, Domanski, A. 2019. Lower Snake River dams: economic tradeoffs of removal; and Lewis, D.J., et al. 2019. The non-market benefits of early and partial gains in managing threatened salmon. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 9	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate section of the FEIS (for example, in water quality, water supply, air quality, recreation, etc.). As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making consistent with NEPA (40 C.F.R. 1502.23). Instead, the EIS set forth eight objectives which, in tandem with the purpose and need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. As described in Chapter 7 of the FEIS, the preferred alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, water supply and greenhouse gas emissions, while minimizing adverse impacts to communities and the economy.
3999	18	ttrue@earthjustice.org	Earthjustice	4. The DEIS fails to describe the risks associated with ecosystems and biodiversity and the socioeconomic consequences 11 The choice among alternatives in the DEIS will affect the degree of risk facing the Columbia/Snake River ecosystem. Some alternatives will increase the level of risk, others will reduce it, and even among those that will reduce risk, the degree of reduced risk will vary. These varying degrees of risk have important implications for the costs and benefits from alternative approaches for managing the CRSO. Notably, recent summaries of the relevant scientific evidence conclude that: [B]iodiversity and ecosystem services are greater in restored than in degraded ecosystems but lower in restored than in intact remnant ecosystems [and there] There is considerable evidence that contemporary biodiversity declines will lead to subsequent declines in ecosystem functioning and ecosystem stability.12 Biodiversity loss is one of the greatest risks of the 21st century. It undermines human health and well-being, societal resilience and progress towards the SDGs. It places severe costs on our economies and makes addressing other global challenges, such as climate change, much more difficult. Ecosystems are moving closer to critical thresholds and tipping points which, if crossed, will result in persistent and irreversible (or very costly to reverse) changes to ecosystem structure, function and service provision, with the potential for profoundly negative environmental, economic and social consequences. The socio-economic case for more ambitious biodiversity action is clear. Thousands of valuation studies are available at the local, regional and global scales, providing estimates of the benefits delivered by biodiversity and ecosystem services (e.g. pollination, climate regulation and water purification). The most comprehensive global estimate suggests that ecosystem services provide benefits of USD 125-140 trillion (US dollars) per year i.e. more than one and a half times the size of global GDP. The costs of inaction on biodiversity loss are high and are anticipated to increase. The world lost an estimated USD 4-20 trillion per year in ecosystem services from 1997 to 2011, owing to land-cover change and an estimated USD 6-11 trillion per year from land degradation. Conserving, sustainably using and restoring biodiversity is vital to achieving many other policy objectives, including human health, climate-change mitigation and adaptation, disaster risk reduction, and water and food security. The benefits derived from biodiversity and ecosystem services are considerable, but are systematically undervalued or unvalued in day-to-day decisions, market prices and economic accounting. Conventional accounting approaches and measures of economic performance (such as GDP) provide only a limited picture of an economys health, and generally overlook the costs of ecosystem degradation.13 Other recent research demonstrates that local loss of biodiversity will affect the functioning and stability of ecosystems at macroscales, so that the stability of a regional ecosystem depends on the total number of species and on the variation in species exhibited by local areas within the regional ecosystem.14 This research highlights the socioeconomic risks stemming from the losses 11 See, for example, OECD. 2019. Biodiversity: Finance and the Economic and Business Case for Action; IPBES. 2019. Natures Dangerous Decline Unprecedented; Species Extinction Rates Accelerating; IPBES. 2019. Global Assessment Report on Biodiversity and Ecosystem Services 12 Isbell, F. 2010. Causes and consequences of biodiversity declines. 13 OECD (2019), Biodiversity: Finance and the Economic and Business Case for Action. 14 Catano, C.P., et al. 2020. Local species diversity, -diversity and climate influence the regional stability of bird biomass across North America Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 10 of biodiversity brought about by the construction and long-term operation of the CRS. The likelihood that these losses will have adverse impacts on the sustainability of the regional ecosystem of the Columbia-Snake River Basin and on the sustainability of sub-regional ecosystems, including that of the Snake River Basin represents a potentially large negative impact on the economic well-being of the Basins residents and of all Americans.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate section of the Final EIS (for example, in water quality, water supply, air quality, recreation, etc.). The EIS also acknowledges the cumulative impacts to affected resources in Chapter 6 for the No Action Alternative as well as Multiple Objective alternative 1, Multiple Objective alternative 2, Multiple Objective alternative 3, and Multiple Objective alternative 4 and Chapter 7 for the Preferred Alternative as well as the climate effects in Chapters 4 and 7.
3999	19	ttrue@earthjustice.org	Earthjustice	The DEIS provides no description of the risks to the Basins ecosystems and their socioeconomic importance, nor does it describe how the CRSO will respond if the undesired outcomes inherent in these risks begin to materialize. As it fails to describe the ecosystem risks, the DEIS also fails to describe the extent to which breaching the Lower Snake River dams would mitigate the risks, and the socioeconomic importance of this mitigation. The most it does is to acknowledge that MO3 would produce the highest likelihood among the alternatives of reducing the risks facing Snake River salmon and steelhead. Leaving the dams in place and continuing their operation largely along lines that have been in place for years will have the opposite effect. Of course, considerable uncertainty exists regarding the potential mechanisms and timing of these risks, but not knowing how and when they will materialize is no excuse for not addressing and disclosing what scientists and economists do know and can say about these risks. Indeed, the uncertainty heightens the necessity for assessing and disclosing these risks so we can take precautionary measures now: When an activity raises threats of harm to human health or the environment, precautionary measures should be taken even if some cause-and-effect relationships are not fully established scientifically. One of the most important expressions of the precautionary principle internationally is the Rio Declaration from the 1992 United Nations Conference on Environment and Development, also known as Agenda 21. The declaration stated: In order to protect the environment, the precautionary approach shall be widely applied by States according to their capabilities. Where there are threats of serious or irreversible damage, lack of full scientific certainty shall not be used as a reason for postponing cost-effective measures to prevent environmental degradation. Because the United States signed and ratified the Rio Declaration, it is bound to use the precautionary principle.15 The Corps itself has explicitly identified and described the risk-management principles and best practices the agency should implement when faced with the kinds of uncertainty and risk posed by a choice among the alternatives in the DEIS: Risk Assessment Risk is typically defined by two characteristics or dimensions the likelihood and the consequence of adverse effects that may be approached in a variety of ways. Likelihood refers to the probability (numerically or qualitatively determined) that an adverse event will occur; consequence refers to the outcomes associated with the uncertain event. In a typical risk assessment, the following questions are addressed as part of the overall risk management process: What can go wrong? What is the likelihood that it will go wrong? What are the consequences?16 15 Tickner, J, C. Raffensperger, and N. Myers. 2006. The Precautionary Principle in action: a handbook. 16 Suedel, B.C., et al. 2012. Application of risk management and uncertainty concepts and methods for ecosystem restoration: principles and best practices. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 11 Nowhere in the DEIS, though, do the Corps and its co-lead agencies ask and answer these questions. Specifically, the DEIS fails to incorporate this guidance about assessing risks, uncertainties and consequences in Section	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate section of the Final EIS (for example, in water quality, water supply, air quality, recreation, etc.). The EIS also acknowledges the cumulative impacts to affected resources in Chapter 6 for the No Action Alternative as well as Multiple Objective alternative 1, Multiple Objective alternative 2, Multiple Objective alternative 3, and Multiple Objective alternative 4 and Chapter 7 for the Preferred Alternative as well as the climate effects in Chapters 4 and 7. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Additionally, the co-lead agencies evaluated many different flow and spill levels and as well as seasonal patterns for when flows are enhanced or reduced. The Preferred Alternative represents an operation that provides a balanced approach between spring and summer flow and spill levels to benefit salmon and steelhead, while also providing benefits to resident fish in the upper portion of the Columbia Basin. Both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies, also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. With respect to the Preferred Alternative, the fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals. Finally, the NMFS and USFWS Biological Opinions demonstrate that CRS operations, maintenance and configuration do not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat and are included as an appendix to the EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				5.2 DECISION FRAMEWORK AND SELECTION PROCESS. Instead of addressing these relevant factors, assessing their significance, and developing appropriate responses to them, the agencies gloss over them. For example, Section 4.2.3.5 Anadromous Fish of the DEIS acknowledges some of the direct risks to anadromous fish [citations omitted]: o Many populations that are sensitive to non-climate threats are also most vulnerable to climate change. Overall, a warming climate could cause moderate to severe declines in salmon and steelhead populations. o Projected changes in stream and river temperatures (as described in Section 4.2.3) may cause direct mortality due to heat stress and greater disease susceptibility if the range of physiological tolerance is exceeded. For example, in the Columbia Basin, Snake River sockeye salmon (Oncorhynchus nerka) are at high risk from heat waves during their mid-summer adult migration. Historical water temperatures have already approached lethal limits for adult steelhead in the upper Snake and middle Columbia Rivers. Thus, even minor increases in thermal exposure put some of these populations above lethal limits. Increases in water temperatures could result in increased use of cold water refuges by adult salmon and steelhead. o But, salmon are becoming smaller and sometimes younger when they return to freshwater, potentially as a result of decreasing pH and increasing temperature. o Where high temperature exposure is already an issue, increasing temperatures inside fishways of dams could worsen thermal exposure for migrating adult sockeye, Chinook salmon, and steelhead. o Climate change is also projected to have consequences for the habitat of anadromous fish during the period of their lifecycle where they reside in the Pacific Ocean and Columbia River estuary. Several trends are expected: Reduction in thermal habitat for salmon Increasing ocean acidification Changing estuarine and plume environments o Outmigrating juveniles could experience increased predation risk as projected warmer water temperatures throughout the Columbia River Basin may increase the proportion of non-native predatory fish and their predation rates on juvenile salmon and steelhead. And Section 4.2.9 Fisheries briefly describes the potential risks to commercial and recreational fisheries.17 o Recreational opportunities could be affected by climate change primarily by changing seasonal access for in-water activities. Projected effects to other resources could also influence visitation related to specific recreational activities. For instance, potential effects to fish and wildlife (Section 4.2.4, 4.2.5) could influence sport fishing and hunting opportunities. Potential effects to water quality (Section 4.2.3) could affect swimming opportunities. o To the extent that climate change effects ameliorate or exacerbate the effects of the Multiple Objective Alternatives on fish in a way that increases or decreases abundance of target species, commercial and ceremonial and subsistence fishing opportunities, and the economic, social, and cultural values associated with them, then fisheries could be affected. Climate change may also affect fisheries if it results in a change in distribution of fish populations that increases the cost associated with fishing, or limits access in some way. Section 4.2.8 Recreation mentions, in general terms, some of the risks to ecosystem-use activities that the agencies apparently consider to be economically important: o Recreational opportunities could be affected by climate change primarily by changing seasonal access for in-water activities. Projected effects to other resources could also influence visitation related to 17 Like others, however, this section does not discuss the economic importance of risks to non-use values of fish and other species and ecosystems as a whole. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 12 specific recreational activities. For instance, potential effects to fish and wildlife (Section 4.2.4, 4.2.5) could influence sport fishing and hunting opportunities. Potential effects to water quality (Section 4.2.3) could affect swimming opportunities. o Climate change has the potential to disrupt hydrological processes that in turn may affect current water supply practices. These changes could affect surface and groundwater users, including users that use free flowing or natural/live6 [sic] flow systems. Climate change has the potential to affect water supply for irrigation, municipal, and industrial uses from surface water sources. Changes in natural/live flow to the system that reduces summer and fall stream flows may reduce the amount of available supply. Nowhere, however, does the DEIS then use the identification of these ecosystem-related risks to describe or discuss the likelihood that the risksindividually and in aggregatewill materialize or the socioeconomic and other consequences that likely would arise if the risks should materialize. Neither does it describe how the agencies and others likely will respond if the risks do materialize. By failing to explicitly identify risks, uncertainties and potential consequences and incorporate them into the decision framework and the process for choosing among alternatives, the action agencies have left out of the DEIS information the public and decision-makers must know to evaluate and prepare for a risky and uncertain future. By failing to evaluate these risks and uncertainties, the agencies hide from the public and decision-makers information they must know if they are to fully understand the basis for the agencies selection of the Preferred Alternative and this alternatives full socioeconomic consequences.	
3999	20	ttrue@earthjustice.org	Earthjustice	5. The DEIS fails to accurately or completely represent socioeconomic information The DEIS does not fully or accurately describe the economic importance of passive-use values (also called non-use values), which embrace the many people who realize a benefit from knowing that healthy and larger fish populations exist. Nor does it use available and credible information or tools to attempt to fully describe and evaluate these values. Moreover, the available research and information shows these values are quite large. For example a 1999 summary prepared for the Army Corps of Engineers reported that:18 The passive-use value of expected increases in fish populations resulting from breaching dams on the Elwha River would exceed $140 million per year. An increase of 1 million in the annual number of salmon returning to Eastern Washington would have a passive-use value of almost $900 million per year. The passive-use value for just the restoration of the free-flowing nature of the Lower Snake River would exceed $420 million per year. While this report is more than 20 years old, more recent research and analysis confirms and expands these values.19 The DEIS states that the agencies evaluated passive-use values and the DEIS contains a section headings called Fisheries and Passive Use (section 6.3.1.15 in Chapter 6: Cumulative effects). The heading of this section, though, is not consistent with the information in it. The information in this section contains only information about benefits people derive from directly interacting with fish through commercial and recreational fishing. That is, the heading for this section indicates it should include information about the passive use, i.e., explain that that fish (and other natural resources) have socioeconomic value insofar as Americans know that these resources exist, and these values are unrelated to uses or direct interactions with the fish. In 18 Loomis, J. 1999. Passive use values of wild salmon and free-flowing rivers. 19 See, e.g., Domanski, A. 2019. Lower Snake River dams: economic tradeoffs of removal; and Lewis, D.J., et al. 2019. The non-market benefits of early and partial gains in managing threatened salmon. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 13 stark contrast, however, the text in this section includes information only about uses of fish, particularly through commercial and recreational fishing, and nothing about passive uses. The disconnect between the heading and the text could not be more severe. How did this happen? How did the co-lead agencies misrepresent and disregard the concept of passive-use value, which is recognized by economists around the world as a key indicator of the socioeconomic value of natural resources? In the past, the Corps has demonstrated it understands the concept of passive-use values. For example, it has estimated that the continued operation of the navigation channel and the four lower Snake River dams would generate passive-use-value costs of up to $420 million annually by impeding the restoration of fish populations associated with more natural habitat conditions.20 Specifically the Corps stated: [Passive use value is] a benefit associated with knowing that a resource exists, even if no use is made of it. These values are typically referred to as passive use, non-use, or existence values. The passive use value of a near-natural lower Snake River was estimated at $420 million per year. These amounts represent the additional passive use value under this alternative relative to an alternative that would continue the fish passage facilities and project operations that were in place or under development at the time the Corps initiated its evaluation of the alternatives. (p. I ES-19) In the 2002 document from which these statements come, the Corps cited a bureaucratic restriction from the now-outdated Principles and Guidelines as its reason for not incorporating these passive use values in its calculation of economic costs and benefits from removing the dams. It did, however, present estimates of passive values as additional information for the decision maker to consider. The DEIS explains [p. 3-1322] that the co-lead agencies did not update the estimate of passive use value from the 2002 report because a review of that report concluded that it offered only a single estimate of the value per fish and did not account for how this value might decrease if fish populations expand or increase if fish populations diminish. The DEIS does not explain why it did not assemble the necessary data and expertise to overcome this limitation, even though it acknowledges that others have done so. Nor does it determine whether or not the 2002 estimate of passive use value reasonably indicates the lower bound of passive use value in the future, insofar as evidence indicates past estimates of passive use values likely understate the value households will place on salmon and other resources in the future (see the discussion of this issue, below). Thus, instead of using the knowledge embedded in the 2002 estimate, whatever its limitations, to inform readers of the importance of future passive use values, the agencies opted to disregard the information all together.	The EIS describes the multiple different ways that people may hold value for salmon and other natural resources, including non-use (i.e., "passive use") values that are not associated with direct experience (e.g., fishing, subsistence). As described in this comment, the EIS (Section 3.15.2.2) summarizes the existing literature on passive use values for salmon, including the studies referenced in this comment, and affirms that the literature demonstrates that the general public holds value for the salmon and that the population that may benefit from increased salmon populations may be geographically far-reaching. However, due to limitations in the literature and uncertainty regarding the changes in overall fish abundance predicted under each alternative (as different fish are affected positively and adversely), the EIS does not rely on this literature to estimate a monetary value of the effects on fish. As is common in NEPA analyses (see 40 CFR 1502.23), the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision making, including the effects of the alternatives on fish as detailed in Sections 3.5 and 7.7.4. That the effects of the alternatives on fish are not quantified as monetized economic values does not mean that they were not considered in the context of the analysis. It is correct that, while Section 6.3.1.15 is titled "Fisheries and Passive Use," Table 6-40 in the Draft EIS is described as "Reasonably Foreseeable Future Actions Relevant to Fisheries." As with commercial, subsistence, and ceremonial fishing, passive use values for fish are tied to cumulative actions that affect fish abundance. These actions are described in Tables 6-19 and 6-21 in the Draft EIS.
3999	21	ttrue@earthjustice.org	Earthjustice	The DEIS also fails to correctly show socioeconomic information regarding the use values for ecosystem services. For example, it does not tell readers and decision-makers about the availability of large amounts of available information collected by multiple agencies and researchers regarding the amounts recreationists are willing to pay when they visit public lands and waters.21 These expenditures represent a lower boundary for the value recreationists place on being able to go fishing for salmon, steelhead, and enjoy other natural resources affected by 20 Corps of Engineers.2002. Final Lower Snake River Juvenile Salmon Migration Feasibility Report/Environmental Impact Statement. This amount would be larger if converted to current dollars. 21 See, for example, U.S. Forest Service. 2020. National visitor use monitoring program; U.S. Department of Interior. 2020. DOI contributions to the economy; Rosenberger, R.S.; E.M. White, J.D. Kline, and C. Cvitanovich. 2017. Recreation economic values for estimating outdoor recreation	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Use values associated with ecosystem services are evaluated in the relevant resource section, for example, in water quality (Section 3.4), water supply (Section 3.12), fisheries and passive use values (Section 3.15), recreation (Section 3.11), and others. Regarding the willingness to pay or social welfare values associated with recreation, the evaluation in Section 3.11.3 used the unit day value (UDV). Many of the reports and research cited by the commenter were reviewed for the recreation evaluation. The procedures described in the Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies (Water Resources Council 1983) (Principles and Guidelines) outline three generally accepted methods for measuring recreational benefits: the unit day value (UDV), the travel cost method, and contingent valuation. The EIS acknowledges that the UDV method can include estimates of economic value that are lower than those found in other available sources (e.g., Recreation Use Valuation Database [RUVD], Benefits Transfer Toolkit). The UDV approach is consistent Corps guidance and provides a consistent approach across all sites in the evaluation.

				economic benefits from the National Forest System; Southwick Associates, Inc. 2009. Potential economics contributions of Spring and Summer Chinook had SAFE for Salmon been in effect; and Flores, L., et al. 2017. The value of natural capital in the Columbia River Basin: a comprehensive analysis. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 14 the CRS.22 The available analyses of these expenditures may indicate the lower-bound for value recreationists place on using these public resources because they do not examine or include the full range of use values or the fact that users may have been willing to pay more. For example, data from the Forest Services national visitor use monitoring program describe recreationists expenditures for travel to and from a recreational site, but not for all activities, such as boating and fishing, at the site. Thus, these data do not include expenditures associated with tackle companies, boat dealers, and other businesses directly related to recreational salmon fisheries.	
3999	22	ttrue@earthjustice.org	Earthjustice	Similarly, the DEIS fails to show socioeconomic information regarding the amount of economic activity (jobs, incomes, etc.) that takes place in the local, regional, and national economies where recreationists make the expenditures related recreational opportunities in the Snake River Basin. Some of these expenditures likely occur at or near the recreational site, but others occur at or near the recreationists residence, which may lie outside the Basin. Some of the expenditures are tied directly to recreationists usage of the resources, e.g., as they purchase groceries for a boat trip. Others are indirectly linked to usage, e.g., as the grocery store pays wages to its workers and these workers, in turn, spend their earnings on other good and services. These subsequent expenditures constitute what economists call the multiplier effect, with the total expenditures equal to the sum of the direct and indirect components. In 2015, economists estimated the direct expenditures and multiplier effect for recreational activities on public lands in Washington State.23 Their research showed that, for the state as a whole, these activities generated direct expenditures of more than $8 billion, and total expenditures of more than $13 billion. They also documented expenditures for recreation on public lands in each county. The co-lead agencies did not incorporate any of this or other similar information into the DEIS, and did not fold it into a detailed, comprehensive description of the potential socioeconomic consequences from each alternative. Thus, the agencies deprived the public and decision-makers from information they could use to assess the alternatives absolute and relative desirability. 22 The amount recreationists have to pay to enjoy a day of fishing typically is less than the total amount they would be willing to pay. 23 Briceno, T., and G. Schundler. 2015. Economic analysis of outdoor recreation in Washington State. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 15	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multiple objective alternatives, including the effects on recreation (Section 3.11). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. A number of articles in the literature have been incorporated into the evaluation (for example, NMFS (2014); McKean et al. (2011); USFWS and US Census Bureau, (2011a); American Sportfishing Association (2013); O Laughlin (2005); Reading (2005); Donnelly et al. (1985)). The potential effects to recreational fishing are assessed qualitatively based on the description of effects to resident and anadromous fish in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. Under MO3, the EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The potential for increases in recreational fishing under MO3 in the Snake River Basin is described in Section 3.11.3.5, which would support jobs, income, and social benefits in Tribal and rural river communities. The effects to anadromous fish under MO3 in other locations would have negligible to minor changes from the No Action Alternative. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. Estimates of general river recreation (non-fishing) in the lower Snake River were described based on the evaluation conducted for the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and EIS. The evaluation in Section 3.11.3.5 describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty, and large range in visitation and consumer surplus values among users
3999	23	ttrue@earthjustice.org	Earthjustice	III. The Socioeconomic Elements and Analyses of the DEIS Do Not Follow the Requirements of the Water Resources Development Act (2007) and the Principles, Requirements, and Guidelines for Federal Investments in Water Resources (PR&G) Until recently, when the Corps and/or Bureau developed water-resource plans, such as the one presented in the DEIS, they prepared the socioeconomic elements of the plans subject to the standards and obligations of the Principles and Guidelines (P&G) developed by the Water Resource Council under the Water Resources Planning Act of 1965. The Water Resources Development Act of 2007 (WRDA) called for a revamping of the P&G and, in 2013, the Council of Environmental Quality, with assistance from other federal agencies, issued the first replacement component, called the Principles and Requirements for Federal Investments in Water Resources, followed soon after by implementation Guidelines (together the PR&G).24 The PR&G apply to a broad range of Federal investments that by purpose, either directly or indirectly, affect water quality or water quantity. More specifically, they apply to (1) existing as well as potential federal investments, (2) investments having a water resources purpose or (direct or indirect) effects on water quality or quantity, and (3) investments being made through a project or a program. The standards and requirements in the PR&G provide required guidance the agencies must follow to satisfy NEPA and its requirement to take a hard look at the socioeconomic (as well as environmental) consequences of Federal actions that directly or indirectly affect investments in water and related resources. These standards and obligations also provide the best guidance currently available for satisfying the requirement to demonstrate a substantial, good faith effort at studying, analyzing, and expressing socioeconomic issues to the public and in decision-making processes. In other words, as they prepared and evaluated the alternatives in the DEIS for the CRSO and selected the Preferred Alternative, the co-lead agencies should have followed the standards of the PR&G but they did not nor did they explain why they did not do so. Specifically, the co-lead agencies should have satisfied the standards from the PR&G described below in their presentation of the socioeconomic information about each alternative and about their basis for selecting the Preferred Alternative.	If an agency is seeking authorization and appropriations from Congress to fund a Federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. Under the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. Section 1502.23 of the CEQ's NEPA regulations (40 CFR 1502.23) addresses the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. Further there is no policy or law that requires the use of the PR&Gs.
3999	24	ttrue@earthjustice.org	Earthjustice	1. The DEIS does not provide detailed, transparent analysis to support its recommendations to the fullest extent possible The standards and requirements established by the PR&G include: Make a substantial, good faith effort at studying, analyzing, and evaluating the socioeconomic issues raised by the alternatives and actions addressed in the DEIS and that will be affected by the decisionmaking process. Use only relevant, accurate, and reliable information. Use all the available information that is relevant, accurate, and reliable. Use evaluation methods that apply an ecosystem services approach. Fully disclose all relevant information to enable the public to understand the rationale for selecting the Preferred Alternative. To satisfy these standards and obligations, the co-lead agencies should have incorporated into the DEIS all the relevant information for describing and evaluating the socioeconomic impacts of each alternative, and for making the best decisions, using reliable, best-practice analytical 24 Council on Environmental Quality. Principles and Requirements for Federal Investments in Water Resources; Interagency Guidelines. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 16 methods. The agencies completely failed to meet these standards and obligations. They did not employ an analytical framework or individual analytical methods established by executive order, OMB guidance, and agency manuals that have been subjected to and passed intense professional scrutiny.25 As a consequence, they assembled a limited and unorganized amount of information on just some relevant issues, made no attempt to specify the criteria they used to search for and select socioeconomic information or to demonstrate that they gathered all the information that is relevant. They omitted vast amounts of clearly relevant, readily available information, including data from government agencies and peer-reviewed research reports. They even failed to include data and research findings prepared and used by the co-lead agencies in earlier planning exercises for the CRSO.26	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate section of the Final EIS (for example, in water quality, water supply, air quality, recreation, etc.). As is common in NEPA analyses (see 40 CFR 1502.23), the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. As described in Chapter 7 of the Final EIS, the Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective alternative 3 which includes the measure to breach the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. Regarding the PR&G requirements, if an agency is seeking authorization and appropriations from Congress to fund a Federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. Under the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. CEQ's NEPA regulations (40 CFR 1502.23) address the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. Further there is no policy or law that requires the use of the PR&Gs.
3999	25	ttrue@earthjustice.org	Earthjustice	The socioeconomic elements of the DEIS also fail to satisfy the standards and obligations for transparency. This failure includes: o The agencies did not provide a comprehensive description of local economies directly affected by the CRSO or of the more distant economies that are indirectly affected (e.g., by decisions that affect orca populations or decisions that may contribute to the development of solar/wind/battery or other clean energy investments).27 For example, the DEIS offers no explanation of the ways in which risks for the Salish Seas orca population might affect local tourism jobs and property values in local communities. It similarly fails to explain powerful forces that affect economic development in the western U.S. and influence population, jobs, incomes, and other characteristics of communities within the Snake River Basin. These forces include the ability of natural resource amenities, such as a healthy ecosystem with abundant salmon-related recreational opportunities, to attract workers, households, and investors to these communities and, hence, to stimulate diverse development across many sectors. o They did not explain the mechanisms by which different decisions for operating the CRS will affect these economies (e.g., they do not explain the mechanism whereby enhancements in natural resource amenities attract workers, households, and investors or analyze these consequences).28 The DEIS includes no discussion of ways in which differences among the alternatives might interact, for example, with the forces and mechanisms that link the availability of nearby natural resource amenities with economic development in local communities. o They did not use readily available information to quantify the potential effects of each alternative on these economies (this is especially true for breaching the Lower Snake River dams in Alternative 3). For example, the DEIS fails to show, evaluate, and incorporate into its decision-making process research that concluded the removal of the Lower Snake River dams would stimulate a net increase in jobs, wages, and the gross 25 See, for example, Executive Order 12866. 1993. Regulatory planning and review; Office of Management and Budget. 2003. Circular A-4: regulatory analysis; EPA. 2002. A framework for the economic assessment of ecological benefits; EPA. 2010. Guidelines for preparing economic analyses; and EPA Science Advisory Board. 2009. Valuing the protection of ecological systems and services. 26 For example, they ignore data they developed in: Corps of Engineers. 2002. Final Lower Snake River Juvenile Salmon Migration Feasibility Report/Environmental Impact Statement. 27 This information is readily available from Headwaters Economics. 2020. Economic profile system, which compiles public data by county and other geographic units. This interactive website was developed with funding from the Bureau of Land Management, USDA Forest Service, and the Kresge Foundation 28 See, for example, Headwaters Economics. 2020. Economic profile system; Pender, John, Alexander Marr, and Richard Reeder. 2012. Rural wealth creation: concepts, strategies and measures; McGranahan, D., T. Wojan, and D. Lambert. 2010b. The rural growth trifecta: outdoor amenities, creative class and entrepreneurial context; Henderson, J. 2002. Building the rural economy with high growth entrepreneurs; Irwin, E.G., A.M. Isserman, M. Kilkenny, and M.D. Partridge. 2010. A century of research on rural development and regional issues; Fisher, B., and R.K. Turner. 2008. Ecosystem service: classification for valuation. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 17 value of goods	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Sections 3.5 and 7.4.4. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective alternative 3, which includes the measure to breach the four lower Snake River dams. However, the Preferred Alternative also meets most other objectives of the EIS for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. The description of how the Preferred Alternative was chosen is provided in Chapter 7 of the EIS. Also, the overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. National Marine Fisheries Service (NMFS) and Washington Department of Fish and Wildlife (WDFW) have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NMFS and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. SRKW also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKW are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKW feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon Smolt-to-Adult return rates would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-lead agencies do not anticipate a lack of hatchery fish in the short-term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). Therefore, there may be short-term adverse effects to the SRKW population as the lower Snake River wild salmon populations adjust to changes associated with dam breaching. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKW, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKW. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NMFS BiOp 2020). The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				and service produced in the regional economy.29 o They did not calculate each alternatives impacts on public benefits, relative to public costs. The DEIS does not mention the benefits and costs that would accrue to the American public from each alternative. o They did not fully show the information and reasoning used to select the Preferred Alternative (e.g., they did not explain their subjective, undocumented weighting of different effects as low, moderate, or otherwise). The DEIS does not compare the net public benefits across the alternatives, and show which alternative promises the greatest net public benefits. It does not use this information to select as its Preferred Alternative the one that promises the greatest net public benefit, or the reasoning for its choice if it choses another as its Preferred Alternative.	Additionally, MO3 is not likely to adversely affect the SRKW distinct population segment in the short term analysis because increased hatchery production and the new trap and haul facility at McNary proposed for MO3 in Chapter 5 would address any potential short-term impacts. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
3999	26	ttrue@earthjustice.org	Earthjustice	2. The DEIS does not demonstrate that the Preferred Alternative will yield sustainable economic development The PR&G establish standards intended to ensure that Federal investments improve economic well-being for present and future generations through the sustainable use and management of water resources. The DEIS, with its inadequate and incomplete socioeconomic analysis and selection of the Preferred Alternative, does not provide a rational basis for achieving this assurance. Indeed, the DEIS does not even provide a framework for defining what sustainable use and management of water resources means in the CRSO context, ascertaining appropriate criteria for measuring sustainable economic development, and applying the criteria to evaluate the different alternatives. In effect, the DEIS shows no serious concern about the potential sustainability of the CRSO impacts on local and regional economies. Instead, the DEIS indicates provides only information about how the CRSO can continue to operate in the future through large investments, of one kind or another. It does not disclose the effects of these investments on the relevant ecosystem and its sustainability, nor does it show other direct, indirect and induced costs and/or benefits that will accrue to the public from these investments. For example: o A review of CHAPTER 4 SOCIOECONOMIC EFFECTS ANALYSIS in Appendix N, reveals that it describes only the potential socioeconomic costs from the impacts of MO3 on water supplies in the Lower Snake River, and fails to describe the potential benefits in this or other areas. These benefits would materialize as this alternative results in improvements in the ability of the ecosystem to provide society with valuable goods and services, such as higher populations of anadromous fish, reduced risk to ecosystems from the interactions between the CRSO and climate change, increased recreational opportunities for the free-flowing river. These impacts will have both usevalues and passive-use values that may be substantial, but the DEIS does not address them identify and analyze them. o The agencies description of the potential socioeconomic costs from the impacts of MO3 on water supplies in the Lower Snake River fails to provide a reasonable, complete assessment of the costs associated with impacts to irrigated agriculture that the DEIS predicts (apart from whether they provide an accurate description of these impacts). They assume [p. N-4-4] that, with implementation of MO3, irrigation no longer would be feasible for 47,926 acres currently being irrigated from surface water and groundwater, and estimate that the lost crop production from these acres would result in a lost social benefit, i.e., socioeconomic cost, of up to $353 per acre per year (and for the next 50 years). The calculation of this amount, however, fails to account for the 29 Domanski, A. 2019. Lower Snake River dams: economic tradeoffs of removal. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 18 benefits American taxpayers would realize as they no longer would have to pay for infrastructure and activities of the CRSO that make the surface and groundwater available.30 In other words, the agencies provide an incomplete, skewed analysis: counting only the costs to farmland owners of MO3, ignoring the benefits to taxpayers, and failing to calculate the overall, net benefits to the American public as a whole (or maybe net costsit is impossible to tell from the information the agencies provide in the DEIS). o The agencies assumption that MO3 would result in the dewatering of 47,926 acres comes from conversations with several extension agents in WA and OR [N-4-18]. The agencies do not explain if this estimate of dewatered acreage represented the findings from a detailed, comprehensive analysis that took a hard look at the issue. It also does not reveal if these conversations included evidence regarding other factors that might influence farmers susceptibility to impacts from breaching the dams. For example, the agencies do not reveal if the conversations included a discussion of or data about markets now and over the next 50 years to assess the likelihood that demand for crops grown on these acres might change over time and, for example, lose some of their access to Asian markets or be outcompeted by other producers. Without such an analysis, it seems likely that projections of the lost social welfare based on these conversations are nothing more than speculation. o Questions about the reasonableness of the agencies failure to disclose the details of the analysis, if any, that yielded the estimates of dewatered acreage and the landowners loss per acre are amplified by some of their assumptions and data manipulations. For example, they calculate the total loss per acre by assuming the annual losses will remain constant for the next 50 years. They apparently made this assumption (they provide no details) without making any assessment of how market conditionsthe supply of and demand for landmight evolve over the next 50 years. They apparently made this assumption (they provide no details) without considering any plausible factors that plausibly might make the future annual loss per acre increase or decrease. These factors include, but are not limited to, changes in international trade relations (e.g., a trade war), crop technologies (e.g., new GMO varieties that require less irrigation), climate conditions (e.g., shifts in rainfall patterns), and irrigation technologies (e.g., the discovery of groundwater supplies and emergence of low-cost pumping systems). Such changes, if not currently anticipated by markets, would not be reflected in current land prices. If the agencies, in fact, failed to consider these factors as part of a detailed, comprehensive analysis of all the factors, including drawdown of the reservoirs, that affect prices of agricultural land in the region, then they violated standards and requirements applicable to this type of analysis.31 If they conducted such an analysis but failed to reveal their data, methods, and findings in the DEIS, then they have violated standards and requirements to make that information transparently accessible to the public and decision-makers.32 At least one of these violations seems to have occurred, undermining the confidence the public can place on the reasonableness of the numbers the agencies present regarding the irrigation impacts of MO3, and raising a reasonable inference that the agencies numbers are arbitrary. o The DEIS similarly fails to account for the benefits to taxpayers that might result if municipal and industrial water users lose subsidized access to water from Federal 30 The calculation, shown in Table 4-1 Irrigated Land Value Using Assessor Data, focuses solely on the benefits landowners realize from irrigation, not on the costs of providing the landowner with subsidized access to the water. 31 See, for example, Office of Management and Budget. 2003. Circular A-4: regulatory analysis. 32 See, for example, the transparency requirements explicitly expressed in the PR&G. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 19 investments in the CRSO. Instead, if focuses solely on the costs to water users. Hence, it is impossible to determine, from the information in Appendix N, Chapter 4 if MO3 would yield an overall net benefit or net cost even in the narrow area of water supply, which is just one of many examples of this problem in the DEIS.	Regarding the PR&G requirements, if an agency is seeking authorization and appropriations from Congress to fund a Federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. One of the goals of a PR&G analysis is to determine the economically justified alternative by conducting an economic cost benefit analysis, referred to as National Economic Development (NED) effects in the superseded P&Gs. Under the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. Measuring the social welfare effects, or NED effects, related to water supply would be time consuming and cannot be completed within the EIS imposed schedule. Section 1502.23 of the NEPA regulations (40 CFR 1502.23) addresses the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. Generally, the PR&Gs are intended as guidance for analyzing Federal investments. Further there is no policy or law that requires the use of the PR&Gs. Appendix N describes the analysis for water supply effects limited to irrigation and municipal water supply.
3999	27	ttrue@earthjustice.org	Earthjustice	3. The DEIS does not demonstrate that the Preferred Alternative will maximize the net public benefits derived from water and related land resources The PR&G emphasizes that Federal resource-managers, such as the co-lead agencies, must demonstrate that their decisions will maximize the net benefits the American public derives from the nations water and related land resources. Toward that objective, the PR&G establishes these standards and obligations: Provide a full comparison of costs and benefits for each alternative, including the Preferred Alternative, giving equal consideration to both effects that are monetized and effects that are not. Provide a forecast relevant to the socioeconomic problems and opportunities the Preferred Alternative is addressing; identify its specific socioeconomic objectives, and its expected ability to achieve them. Design the Preferred Alternative so that the public benefits will justify the Federal investments. Demonstrate that the Preferred Alternative will accomplish the Federal objective, by maximizing public benefits, thereby producing an increase in the net value of the national output of goods and services, marketed and not marketed. The co-lead agencies make no reference to these standards and obligations. They make no demonstrable effort to satisfy them. As described above, they ignore non-monetized costs and benefits. They ignore [monetized] costs and benefits that accrue to the public rather than to the agencies, themselves, or, in some cases, to their affected industries (e.g., hydropower, navigation, and irrigated agriculture). They do not conduct an analysis that identifies the socioeconomic problems and opportunities they are addressing in the DEIS and the Preferred Alternative.33 They do not demonstrate the Preferred Alternative has the ability to resolve the identified socioeconomic problems and to capitalize on the socioeconomic opportunities so that it (a) will yield positive net benefits to the American public, or (b) that it will yield greater net public benefits than other alternatives, especially the alternative that involves restoring the lower Snake River and breaching four dams there. These failings directly contradict the emphasis the PR&G place on ensuring that the Federal investment promotes the sustainable use and management of the nations water and related resources, thereby contributing to economic well-being for present and future generations. The Principles and Requirements identify sustainable economic development as one of the core principles that must guide Federal investments in water and related resources. Furthermore, it states, Federal investments in water resources as a whole should strive to maximize public benefits, with appropriate consideration of costs. Public benefits encompass environmental, economic, and social goals, include monetary and non-monetary effects and allow for the consideration of both quantified and unquantified measures.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate section of the Final EIS (for example, in water quality, water supply, air quality, recreation, etc.). As is common in NEPA analyses (see 40 CFR 1502.23), the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies' numerous legal obligations. As described in Chapter 7 of the Final EIS, the Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective alternative 3, which includes the measure to breach the four lower Snake River dams. However, the Preferred Alternative also meets most other objectives of the study for the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Regarding the PR&G requirements, if an agency is seeking authorization and appropriations from Congress to fund a Federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. Under the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. Section 1502.23 of the CEQ's NEPA regulations (40 CFR 1502.23) addresses the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. Further there is no policy or law that requires the use of the PR&Gs.
3999	28	ttrue@earthjustice.org	Earthjustice	The DEIS does not assess each alternatives potential for sustainable production of the quantity, quality, timing, location, accessibility, etc. of goods and services produced by the economy or the ecosystem. It also does not assess the sustainability of jobs, incomes and other relevant indicators of economic activity. And it omits or understates the sustainable economic impacts of environmental improvements that would result from dam breaching. As a consequence, its 33 Note: the specification of Purpose and Need does not satisfy this standard or provide an explanation for its failure to	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. The EIS does not employ a cost-benefit framework for decision-making. This is because, consistent with NEPA analysis frameworks (see 40 C.F.R. 1502.23), the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. Consequently, a focus solely on the monetized economic costs and benefits would exclude important tradeoffs associated with the alternatives communicated in the EIS, including effects on fish. Furthermore, while a cost-benefit framework generally results in a ratio of overall benefits to costs, the EIS evaluates the performance of the CRSO alternatives with respect to multiple stated objectives, for example related to improving fish passage and survival, reliable power generation, and minimizing greenhouse gas emissions.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				do so. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 20 description and analysis of the Preferred Alternative does not demonstrate that it is superior to the other alternatives in its ability to generate net public benefits as described in the PR&G.	
3999	29	ttrue@earthjustice.org	Earthjustice	The DEIS presents a misleading and partial account of each alternatives impacts on a few selected and narrow market components of the economy (some commercial/industrial sectors). For example, it describes benefits from the navigation infrastructure for the barge industry and its clients under the Preferred Alternative, but it does not describe the benefits the rafting/paddling industry or other sport and recreational components of the economy would realize under Alternative 3, when breaching of the dams would restore free-flowing water in the Lower Snake River. Nor does it attempt to identify and describe the potential economic benefits of the investments necessary to river restoration or the economic potential of restoration of more than 14,000 acres of currently inundated riparian habitat, benefits that could even include additional agricultural activity. The DEIS recognizes the costs of breaching the dams and making compensatory investments in transportation and irrigation, but not the benefitsincreases in output of goods and services, increased local economic activity, including job creationfor example. It similarly recognizes but does not describe the socioeconomic benefits that would flow from investments in the solar/wind generators and related infrastructure that replace forgone hydroelectricity from the Lower Snake River dams.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses (see 40 CFR 1502.23), the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Sections 3.5 and 7.7.4. That the effects of the alternatives on fish and recreation are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective alternative 3, which includes the measure to breach the four lower Snake River dams. However, the Preferred Alternative also meets other objectives of the EIS for resident fish,J amprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Under MO3, the EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. A range of visitation is provided, based on the evaluation conducted for the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and EIS. In addition, the potential for visitation under MO3 in the lower Snake River in the long-term is predicated on that access would be developed for the resource. As described in Section 3.11.3.5, access to the river and its recreational opportunities will be paramount for the reestablishment of river visitation to the lower Snake River. For example, parking lots, boat launches, new trailheads, access roads, etc., would need to be developed to facilitate the drawing of visitors to the region." The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. National Marine Fisheries Service (NMFS) estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. Regarding the regional economic effects of the investments, the regional economic effects associated with the expenditures under the Multiple Objective alternatives are described in Section 3.19.3 and Appendix Q, Annex C. In the short-term, the regional economic benefits of construction under MO3 are higher than the other alternatives. However, in the long-term, lower regional economic benefits would occur under MO3 from reduced fish and wildlife mitigation spending, depending on Bonneville's Fish and Wildlife Program costs and resulting mitigation commitments. Regarding the potential for agricultural development on currently inundated lands under MO3, the co-lead agencies would no longer operate project lands after the projects are de-authorized. Under MO3, it is anticipated that the Corps would retain jurisdiction over the land holdings throughout the implementation period and biological evaluation process and that public control of a portion of public lands would be necessary to protect the environmental and natural benefits to salmon associated with dam breaching. Post dam breaching, the Corps may choose to transfer the lands to another Federal or state agency. It is uncertain and speculative to indicate that these lands would be available for agriculture. While it is true that investment in solar, wind, and other replacement resource investments would create economic benefits to the region, these effects are heavily dependent on which resource is constructed, where they are located in the region, and potentially how the construction is financed. The EIS acknowledges that these economic benefits would occur as a result of new resource development, but there is too much uncertainty to quantify this benefit. The potential for agricultural activities in the currently inundated area and associated effects would depend on multiple subjects for which information is not reasonably ascertainable, including the soil types, drainage conditions, topography, and water availability. Without this information, it is not feasible to determine if land can even be used for crops and, if so, for what type(s) of crops. Such an analysis would also need to consider additional information that is not available, such as the cost of land development (leveling, irrigation equipment, drainage infrastructure, pumps). To say that the inundated lands are suitable for crop production and that the agricultural benefit would outweigh the development costs is therefore speculative and not based on high quality information.
3999	30	ttrue@earthjustice.org	Earthjustice	At least some of these investments likely would materialize outside the CRSO river basins, but the DEIS fails to look that far afield for evaluating these benefits. This near-sighted focus contrast sharply with its broad (west-wide) concern for what it characterizes as the potential economic effects on electrical ratepayers. In Appendix J, CHAPTER 4 SYSTEM RELIABILITY, for example, the agencies evaluate the ability to meet forecasted electric load for the entire NW-US system, i.e., the northwest portion of Columbia River System in the United States. In reporting their analysis, the agencies recognize both the interconnectedness between the CRSO and other elements of a broader market and electricity network, as well as the importance of accounting for recent events and up-to-date forecasts.34	The statement that the EIS analyzed region-wide power system reliability is consistent with the EIS power analysis methodology. The EIS recognizes the interconnectedness and interactions across various regions of the power system as described in Section 3.7.3.2 Affected Environment and the power generation as well as greenhouse gas emissions effects were analyzed for the entire western United States (see Sections 3.7.3 and 3.8.3 and Chapter 7 of the Draft EIS). The EIS generally assumes replacement resources would occur within the Northwest in order to best address any effects of the CRSO EIS alternatives on regional reliability (see Section 3.7.3.1, Methodology and Chapter 2 of Appendix H for additional description of this methodology of the Draft EIS). The locations were selected for both performance of the wind and solar resources as well as for transmission interconnection. However, these resources could be acquired from any competitively priced resource option. While the EIS identified potential replacement portfolios, these were viewed as broad options representing the range in costs and generation characteristics that might be selected, but they are not necessarily the exact resources or locations that would be acquired. More analysis would be warranted to select the optimal mixture of replacement resources with the most current cost information and technological advances.
3999	31	ttrue@earthjustice.org	Earthjustice	The ecosystems affected by the CRSO are arguably even more interconnected and stretch over more distant horizons. Recent research demonstrates that local loss of biodiversity will affect the functioning and stability of ecosystems at macroscales, so that the stability of a regional ecosystem depends on the total number of species and on the variation in species exhibited by local areas within the regional ecosystem.35 Conversely, macro-level disturbances, such as those involving global warming, can have intense ecosystem impacts at microscales. Operation of the CRSO can interact with the status, processes, and functions, of ecosystems across all these levels. Moreover, the socioeconomic risks are high. Multiple lines of analysis indicate that the value of services derived from ecosystems can far exceed the value of goods and services derived from human-built systems.36 The agencies therefore should have evaluated the 34 The spatial and temporal connectedness and uncertainty are reflected, for example, in these statements: It is important to note that since the analysis for LOLP in the CRSO EIS was launched in 2017, utilities in the Pacific Northwest have announced the retirement of additional coal generation plants. Therefore, the analysis described here may be viewed as the 2017 view of the future. BPA is performing additional analyses to evaluate how these results would differ with fewer coal plants serving northwest loads. The reliability analyses were regional (NWUS) and were not performed for the CRS (Federal), Mid-Columbia, or Canadian systems. Because the utilities in the region can buy and sell power bilaterally with one another that is surplus to their retail load needs, the loss of generation by one entity can have adverse consequences to utilities relying on such generation. {J-4-1, and J-4-2] 35 Catano, C.P., et al. 2020. Local species diversity, -diversity and climate influence the regional stability of bird biomass across North America 36 Hejnowicz, A.P., and M.A. Rudd. 2017. The value landscape in ecosystem services: value, value wherefore art thou value? Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 21 uncertainties and risks and determined how well each alternative would increase or decrease the likelihood of undesirable ecosystem outcomes at scales at least as large as and over a period of time at least as long as their analysis of rate impacts. That is, the available evidence suggests that the agencies should be at least as concerned about describing for the public and decisionmakers how the different alternatives might affect and be affected by ecosystem changes as they are about how they affect reliability of the electricity system and consumer rates. The DEIS, however, pays no attention to macroscale and microscale interactions between the CRSO and ecosystems, about how these interactions might exacerbate or mitigate uncertainties and risks for ecosystems near and far, or about the socioeconomic imperative for determining the potential effectiveness of each alternative for managing the uncertainties and risks for the public good. As a consequence, it fails to describe the potential adverse impacts of each alternative on the sustainability of the regional ecosystem of the Columbia-Snake River Basin, the larger ecosystems that extend into the Pacific Ocean, and on the sustainability of subregional ecosystems, including those of the Snake River Basin and the Lower Snake River. This failure constitutes a large gap in the ability of the DEIS to demonstrate that the co-lead agencies understand and have the ability and determination to objectively evaluate the narrow issues they do examine against the potentially large negative impacts to ecosystems and the publics socioeconomic well-being.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate section of the Final EIS (for example, in water quality, water supply, air quality, recreation, etc.). The EIS also acknowledges the cumulative impacts to affected resources in Chapter 6 for the No Action Alternative as well as Multiple Objective alternative 1, Multiple Objective alternative 2, Multiple Objective alternative 3, and Multiple Objective alternative 4 and Chapter 7 for the Preferred Alternative as well as the climate effects in Chapters 4 and 7. The sustainability of ecosystems is outside the scope of the CRSO EIS.
3999	32	ttrue@earthjustice.org	Earthjustice	More broadly, the DEIS fails to identify and evaluate the socioeconomic importance of each alternatives potential impacts on all non-market components of the economy. It does not quantify and estimate the socioeconomic value of increases in subsistence activities that might occur in response to increases in fish populations, for example, or the losses that would occur in response to further declines beyond those that have already occurred. It does not provide any meaningful description of the potential increase in well-being associated with the non-use, or passive use, values the public would assign to increases in population for anadromous fish and other species, to the restoration of a free-flowing water in the Lower Snake River, and to other resources enhanced by breaching the dams. It does not describe in a complete and transparent way the socioeconomic importance of reductions in well-being that past and on-going reductions in these values inflict on Tribal members and others who assign uniquely high benefits to these non-use values, or of the additional socioeconomic losses that would occur with continuation of current river operations under the Preferred Alternative.37 Moreover, the DEIS fails to recognize the research that indicates restoration of a free-flowing river likely would make local communities more attractive to many workers, families, and investors, providing a long-run boost to the sustainability of economic development.38 37 This failure becomes more glaringly apparent when the DEIS identifies, but then incompletely or inaccurately describes the reduction in well-being that would occur if breaching of the dams led to the cessation of river-boat tourism and caused Clarkston and nearby communities to lose their riverboat business without symmetrically identifying impacts of selecting an alternative that continues these activities to Tribal communities that have lost their ancestral character or for the rafting/paddling communities of interest that would realize an increase in well-being from restoration of the free-flowing character of the river with breaching of the dams. Nor does the DEIS address the effects of the choice among alternatives on communities of the Salish Sea that would lose their whale-watching character and culture associated with these whales if implementation of the Preferred Alternative were to stimulate reductions in orca populations. While these more geographically remote communities are within the area the DEIS analyzes for some impacts (e.g., electric rates), they are omitted here and elsewhere. 38 38 Headwaters Economics. 2020. Economic profile system; Pender, John, Alexander Marr, and	As is common in National Environmental Policy Act analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Sections 3.5 and 7.7.4. That the effects of the alternatives on passive use for fish are not expressed quantitatively (e.g., monetized economic values) does not mean that they were not considered in the context of the analysis. The EIS describes the multiple different ways that people may hold value for salmon and other natural resources, including non-use (i.e., "passive use") values that are not associated with direct experience (e.g., fishing, subsistence). Section 3.15.2.2 of the EIS summarizes the existing literature on passive use values for salmon and affirms that the literature demonstrates that the general public holds value for the salmon and that the population that may benefit from increased salmon populations may be geographically far-reaching. However, due to limitations in the literature and uncertainty regarding the changes in overall fish abundance predicted under each alternative (as different fish are affected positively and adversely), the EIS does not rely on this literature to estimate a monetary value of the effects on fish. The information on values that people hold for these fish is then presented throughout the document (e.g., Section 3.15 on commercial fisheries, subsistence and passive use and Section 3.11 on recreational fishing). Additionally, the EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. National Marine Fisheries Service (NMFS) estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing for anadromous fish under Multiple Objective alternative 3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities.

				Richard Reeder. 2012. Rural wealth creation: concepts, strategies and measures; McGranahan, D., T. Wojan, and D. Lambert. 2010b. The rural growth trifecta: outdoor amenities, creative class and entrepreneurial context; Henderson, J. 2002. Building the rural economy with high growth entrepreneurs; Irwin, E.G., A.M. Isserman, M. Kilkenny, and M.D. Partridge. 2010.	The co-lead agencies selected the size of the study area based on the area where the impacts from the proposed structural and operational measures are expected to occur. This study area is sufficient for the agencies to understand the effects of the different alternatives and to enable the agencies to make an informed evaluation of the alternatives. The co-lead agencies focused on the locations where there were understandable direct effects, as opposed to third and fourth order effects, which are harder to predict, and thus evaluate, as a part of the NEPA process. Based on the fish analysis in Section 7.7.4 of the Draft EIS, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible.
3999	33	ttrue@earthjustice.org	Earthjustice	The asymmetrical and, hence, incomplete and misleading nature of the agencies failure to recognize, describe, and quantify the positive correlation between a free-flowing river and overall economic development becomes more glaring when considered alongside the agencies narrow focus on the economic importance of the current beneficiaries of existing river and dam operations. This disconnect in the scope of the analysis emerges, for example, as the DEIS uses obsolete data that masks the long-standing and on-going declines in the value of navigation demand for the locks and reservoirs on the Lower Snake River and its cursory description of the factors that contribute to these declines.39 These declines reflect many factors, including decreases in crop production and competition for barges from rail and truck transportation. Shipments likely will fall further in the future, insofar as the current market forecast expects U.S. wheat prices, acreage, and exports to decline:40 [W]heat plantings are expected to slowly decline. Exports are expected to remain flat as the U.S. share of global wheat trade continues to decline. Wheat prices parallel corn prices, dropping in the second half of the decade, in part due to increasing yields combined with relatively stable planted acreage.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate section of the Final EIS (for example, in water quality, water supply, air quality, recreation, etc.). Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS shows. It is true that barge movements on the Snake/Columbia river have declined somewhat over the past 20 years but the decline has stabilized over the past 10 years. That decline is most likely attributable to investments in shuttle rail terminals. The EIS utilizes the most recent 10 year average as a basis for its forecast volume of freight that would transit on the lower Snake River.
3999	34	ttrue@earthjustice.org	Earthjustice	The flaws in the DEIS are not limited to the co-lead agencies omitting information that suggests benefits from the CRSOs navigation system likely will decline in the future. The agencies similarly fail to report information that suggests the benefits from hydropower generation also will decline. This decline likely will come primarily from tougher market competition, as prices for electricity generated from solar and wind continue to fall dramatically, and new energystorage technologies, increases in energy efficiency and expanded demand response capabilities enable grid operators and others to derive increased economic benefits from other sources of energy production and allow consumers to both enjoy solar- or wind-generated power even when the sun doesnt shine and the wind doesnt blow and reduce their use of electricity overall.41 The DEIS also does not acknowledge the growing demand for these kinds of products and services except in examining the potential economic costs of replacing the power from the lower Snake River dams with clean energy and even in this narrow analysis, the information the agencies present is incomplete and misleading.42 By incorporating an incomplete and inaccurate slice of information about navigation and hydropower markets, the DEIS overstates the benefits Americans reasonably should expect from those beneficiaries of the Preferred Alternative. Those benefits also likely will shrink in the coming years. In contrast, the DEIS omits a broad body of data and research findings that suggest the benefits from breaching the Lower Snake River dams will grow or, conversely, the costs from implementing the Preferred Alternative and not breaching the dams will grow. In sum, the DEIS presents a materially incomplete, biased, and inaccurate picture of the costs and benefits of the alternatives, especially those associated with the preferred alternative and those associated with MO3, the river restoration and dam breach alternative. A century of research on rural development and regional issues; Fisher, B., and R.K. Turner. 2008. Ecosystem services: classification for valuation 39 For more information about the evidence underlying this discussion of declining demand for navigation, see the comments of Lin Laughy. 40 USDA, Office of the Office of the Chief Economist, World Agricultural Outlook Board, Interagency Agricultural Projections Committee. 2019. USDA agricultural projections to 2028. 41 See. For example, NREL. 2020. Declining renewable costs drive focus on energy storage; IRENA. 2017. Electricity storage and renewables: costs and markets for 2030; Whitlock, R. 2019. BNEF revises forecast for global investment in energy storage; and NREL. 2019. Cost projections for utility-scale battery storage. 42 For more information about the evidence underlying this discussion of changing energy markets and the analysis in the DEIS, see the comments of Northwest Energy Coalition on the DEIS. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 23	The EIS does evaluate competitive pressures on regional hydropower as well as the potential effects of future climate change scenarios on changes to hydropower generation (see Draft EIS Sections 4.2.5 and 7.8 for climate change results by scenario and Sections 3.7.2.5, pages 3-801-802 and Section 3.7.3.1, pages 3-842-843 for discussions on the importance of upward rate pressure on Bonneville rate competitiveness). The EIS additionally acknowledges that the energy sector is constantly undergoing transformation and that technological improvements would likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Council in their Seventh Power Plan (Seventh Power Plan page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. The use of battery storage technologies is considered a long-term resource of the Seventh Power Plan, but has become more commercially available since the release of the Seventh Power Plan, will likely be a primary resource in the Council's Eighth Power Plan, and is included in the EIS. The EIS zero-carbon portfolios include demand response, and all cost-effective conservation is included in the load forecast. The EIS also addresses trends in renewable development in the region (see Draft EIS Section 3.7.2.1). To further address concerns about potential reductions in resource costs, consistent with the comment, publicly released draft information, such as updated prices for solar and battery storage, from development of the Eighth Power Plan is included as a new rate sensitivities in the Final EIS. The Final EIS includes the de-escalating cost curves (declining future cost trends for renewables) prepared by the National Renewable Energy Laboratory (NREL) that will likely be used by the Council in the Eighth Power Plan. Based on responses to public comments, the Final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. (See Chapter 3, Section 3.7.3.1 and Appendix H, Chapter 2). Access to barge transportation is the most cost effective means of accessing export markets for the majority of grain producers in the Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS shows. It is true that barge movements on the Snake/Columbia river have declined somewhat over the past 20 years but the decline has stabilized over the past 10 years. That decline is most likely attributable to investments in shuttle rail terminals. The EIS therefore utilizes the most recent 10 year average as a basis for its forecast volume of freight that would transit on the lower Snake River.
3999	35	ttrue@earthjustice.org	Earthjustice	4. The DEIS provides no science-based explanation for why the agencies use zero as the passive use value of salmon; marine species, such as orcas; free-flowing rivers; and other natural resources; as well as the health and functions of ecosystems, despite at least 18 studies that show the value is much greater. In Chapter 3, section 3.15.2.2 Passive Use, the agencies recognize that salmon; marine species, such as orcas; free-flowing rivers; and other natural resources; as well as the health and functions of ecosystems all provide Americans with socioeconomic benefits that economists call passive use values. For example, the DEIS [pp. 3-1317 1319] states: o Passive use values, also referred to as non-use values, are the values people hold for the continued existence of a resource beyond any current or future use. These values are thought to measure the intrinsic values people hold for natural resources or ecological health and functioning. o This review prioritizes studies focused on regional fish species found in the Columbia and Snake rivers and includes results from both primary survey research and benefit transfer methods. o Existing research also suggests that people may hold passive use values for other resources and species found in the Columbia and Snake River Basins, including marine species that prey on salmon as well as other threatened and endangered species. Additionally, the economics literature includes research on passive use values for free-flowing rivers. These studies generally bundle the environmental changes associated with free-flowing rivers, including, for example, specifying effects on fish populations. This section focuses on passive use research on o salmon. o This analysis acknowledges that the general public holds passive use values, and that the population that may experience social welfare benefits from increased salmon populations may be geographically far-reaching. The bottom line: the agencies admit that Americans derive a socioeconomic benefits from salmon; marine species, such as orcas; free-flowing rivers; and other natural resources; as well as the health and functions of ecosystems. They admit that this value has been and can be analyzed and described in economic terms. Yet they treat the value of the socioeconomic benefit as being zero. They offer no explanation for this approach.	This comment correctly summarizes the EIS assessment of the existing literature describing passive use values for salmon. As described, Section 3.15.2.2 concludes that the literature consistently identifies that the general public holds value for the salmon beyond any direct or indirect use (e.g., fishing, wildlife view, subsistence, etc.). Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on passive use for fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis or are implicitly assigned a value of zero. As described in Section 3.15.2.2, the economics literature includes research on passive use values for free-flowing rivers. These studies generally bundle the environmental changes associated with free-flowing rivers, including, for example, specifying effects on fish populations. Thus, passive use values for free-flowing rivers are not necessarily distinct from or additive with passive use values for the fish within these rivers. The overall health and condition of the Southern Resident killer whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. National Marine Fisheries Service (NMFS) and Washington Department of Fish and Wildlife (WDFW) have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NMFS and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. SRKW also are known to eat some steelhead, coho, and chum salmon, halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKW are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKW feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon Smolt-to-Adult return rates would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). Therefore, there may be short-term adverse effects to the SRKW population as the lower Snake River wild salmon populations adjust to changes associated with dam breaching. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKW, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKW. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. Additionally, MO3 is not likely to adversely affect the SRKW distinct population segment in the short-term analysis because increased hatchery production and the new trap and haul facility at McNary proposed for MO3 in Chapter 5 would address any potential short-term impacts.
3999	36	ttrue@earthjustice.org	Earthjustice	The agencies also recognized that extensive research provides quantitative estimates of the passive use values associated with salmon and other resources that would be enhanced under MO3: o A total of 18 studies were identified that estimate passive use or TEV [total economic value] for salmon of relevance to the Columbia River Basin ecosystem, including 13 primary studies and 5 studies employing benefit transfer methods. o Every primary study included in this review identifies positive average WTP [willingness to pay] values for Pacific salmon, meaning the existing body of research consistently finds that the surveyed populations hold some value for salmon beyond any direct or indirect use. These statements are important: the agencies found 13 studies, by professional economists following analytical protocols, that directly provide evidence of the passive use value of salmon in the Columbia River System, and these studies consistently show that Americans realize a passive use benefit from salmon. Another five studies bolster these findings by finding passive use values for salmon in other, nearby locations. Despite recognizing this strong evidence, the agencies used zero as the passive use value of the alternatives considered in the DEIS, regardless of how each alternative affected salmon; marine species, such as orcas; free-flowing rivers; and other natural resources; as well as the health and functions of ecosystems. That is, they decided not to count passive use values in their Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 24 description and analysis of MO3, or to consider passive use values in their comparison of the alternatives and the selection of the Preferred Alternative. The subsequent chapters of the DEIS, which describe similarities and differences among the alternatives, compare the alternatives, and select the Preferred Alternative, contain no substantive statements regarding the passive use value of salmon; marine species, such as orcas; free-flowing rivers; and other natural resources; as well as the health and functions of ecosystems. In other words, wherever the DEIS might show an estimates of the passive use value for any resource, the agencies treat that value as zero.	This comment is consistent with Section 3.15.2.2 of the EIS that summarizes the literature on passive use values, concluding that the literature consistently identifies that the general public holds value for the salmon beyond any direct or indirect use (e.g., fishing, wildlife view, subsistence, etc.). Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. Assessment of the beneficial and adverse effects across the alternatives included careful evaluation regarding effects on fish (as described in Sections 3.5 and 7.7.4). The information on values that people hold for these fish is then presented throughout the document (e.g., Section 3.15 on commercial fisheries, subsistence and passive use and Section 3.11 on recreational fishing). That the effects of the alternatives on passive use are not expressed as monetized economic values (i.e., quantified) does not mean that they were implicitly assigned a value of zero or that they were not considered in selecting an alternative.
3999	37	ttrue@earthjustice.org	Earthjustice	Why? What reasons do the agencies give for disregarding evidence that they acknowledge is available and shows non-zero passive use values? The agencies offer five reasons, but each lacks a scientific basis. The agencies first reason is that the 18 studies dont provide a single, certain estimate of passive use value. o While the existing literature identifies a positive WTP [willingness to pay] for improving salmon populations, it is also clear that the specific value of a given population-level effect is uncertain. The agencies provide no statistical or socioeconomic evidence to back up this statement, however. They never provide any recognized criteria for determining that the specific estimate of passive use value is too uncertain to warrant inclusion in the chapters that describe the alternatives, analyze them, and use the analytical findings to justify selection of the Preferred Alternative over MO3. Nor do they explain why it is necessary to have a certain and specific value of a given population level effect before any estimate of passive use values	The EIS provides a qualitative discussion of passive use values for fish and does not imply that the values and impacts of the alternatives are zero. As described in Section 3.15.2.2, the existing literature on passive use and Total Economic Values (TEV) for salmon is generally based on changes in overall salmon abundance. The co-lead agencies agree that the studies do not need to identify a specific value of the specific population change relevant to the alternatives to inform the passive use effects of the alternatives. However, first, the literature generally evaluates passive use benefits of large-scale population changes (including "restoring" salmon populations, "delisting" species, or doubling population sizes). Values people hold for such changes are not necessarily scalable for more marginal changes in population levels. Second, the given population change for the CRSO EIS alternatives would need to be known to apply this literature. Due to the complexity in modeling changes in abundance for anadromous fish, the fish effects analysis in Sections 3.5 and 7.7.4 assesses effects of the alternatives on fish in terms of multiple different metrics, identifying a mix of beneficial and adverse effects depending on the specific type of fish, and assessing abundance effects only for some stocks. Note that life cycle model abundance estimates were only produced for a subset of Columbia River System species as described in Chapter 3.5.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				can be considered or accounted for. And nothing in the literature on identifying and using passive use values indicates that they can be employed only where a specific value of a given population level effect is available. The agencies first reason for disregarding these values and the evidence of their magnitude is irrational and not support by the available and relevant information.	Benefit transfer is a methodology that applies results from existing relevant studies to a new resource or context. Best practices for benefit transfer for Federal agencies identified in the Office of Management and Budget (OMB) Circular A-4 describe that meeting all criteria for a reliable benefit transfer is difficult and that professional judgment is required in determining whether a particular transfer is too speculative (OMB 2003, 26). This EIS does not include a quantitative benefit transfer of passive use values but instead presents the findings of the existing literature acknowledging that the general public holds passive use values, and that the population that may experience social welfare benefits from increased salmon populations may be geographically far-reaching. In selecting an alternative, the effects on fish of each alternative were considered carefully in the context of all of the types of socioeconomic values (e.g., commercial and recreational fisheries, subsistence, passive use, etc.) This approach does not constitute disregarding the literature or the evidence of the magnitude of fish values, as described in this comment.
3999	38	ttrue@earthjustice.org	Earthjustice	The agencies second reason for disregarding the results from the 18 studies is that some of the studies were conducted 20-30 years ago. o Studies conducted 20 to 30 years ago rely on outdated survey methodologies and baseline conditions for salmon populations, calling into question whether they accurately reflect current values held by the public The agencies never offer any scientific, analytical support for concluding that it is reasonable for them to disregard estimates of passive use values from older studies. This omission stands out, because they acknowledge the existence of scientific research that appliedindeed, helped defineapplicable protocols and found that, over time, the passive use values American households place on salmon and other at-risk species have been increasing.43 This evidence supports the conclusion, that findings from the earlier studies cited in the DEIS probably understate the current passive use values but have not become irrelevant. It also supports the conclusion, that findings from all of the studies cited in the DEIS, including the most recent, probably understate the passive use values that will exist in the future. In other words, the evidence the agencies recognize as relevant supports the conclusion, that, over the DEISs period of analysis, the passive use values of salmon; marine species, such as orcas; free-flowing rivers; and other natural resources; as well as the health and functions of ecosystems will be at 43 Richardson, L., and J. Loomis. 2008. The total economic value of threatened, endangered and rare species: an updated meta-analysis Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 25 least as great as the values indicated by the 18 studies. The agencies simply never offer a rational explanation for their decision to disregard the passive use values indicated by the 18 studies they identify because some of them were completed years ago.	This EIS does not include a quantitative benefit transfer of passive use values but instead presents the findings of the existing literature acknowledging that the general public holds passive use values, and that the population that may experience social welfare benefits from increased salmon populations may be geographically far-reaching. The EIS describes that the studies conducted 20 to 30 years ago rely on outdated survey methodologies and baseline conditions for salmon populations. Although there is reason to believe that passive use values by people have been increasing over time, the older studies do not apply the state of science methods for eliciting information on these values. This discussion in the EIS does not state that the passive use values literature is overestimating (or underestimating) values people hold for salmon. Rather, it identifies the various complexities with applying this literature to provide a monetized estimate of the passive use value effects of the CRSO EIS alternatives. In selecting an alternative, the effects on fish of each alternative were considered carefully in the context of all of the types of socioeconomic values (e.g., commercial and recreational fisheries, subsistence, passive use, etc.) This approach does not constitute disregarding the literature or the evidence of the magnitude of passive use values, as described in this comment.
3999	39	ttrue@earthjustice.org	Earthjustice	The agencies third reason for disregarding the results from the 18 studies is that some of the newer studies had too narrow a focus to satisfy the agencies. o The more recent surveys have generally involved small sample sizes, and narrowly define the resource change (e.g., restoring salmon or removing a specific dam). That is, the agencies discarded the estimates of passive use value from some studies because they felt that they did not gather data from a large enough sample of households to satisfy the agencies or because they looked at removing just a specific dam. The agencies, however, provide no explanation or analysis to support their conclusion that these studies are entirely irrelevant to the socio-economic effects of the actions they are considering. They never explain, for example, how large a sample must be for them to accept a studys findings or what analyses support their apparent conclusions about adequate sample size. They never recognize that the passive use value from removing one dam may provide an appropriate reference point for estimating the value from removing others. Nor do they identify evidence that explains why this would not be the case. They dont apply the principles of statistical analysis to describe how, from the data available to it, each of the studies provided two results: the most likely single-point estimate of passive use value, and an estimate of the extent to which the true value might be larger or smaller. Instead of evaluating these aspects of each studys findingswhich the agencies, themselves, determined to satisfy standard analytical protocolsthe agencies, instead, disregarded the studies findings altogether.	This EIS does not include a quantitative benefit transfer of passive use values but instead presents the findings of the existing literature acknowledging that the general public holds passive use values, and that the population that may experience social welfare benefits from increased salmon populations may be geographically far-reaching. The EIS does not state that the more recent passive use research that involves smaller sample sizes is "irrelevant to the socioeconomic effects." In fact, the findings of these studies are presented for consideration. The discussion in the EIS of passive use values does not state that the passive use values literature is overestimating (or underestimating) values people hold for salmon. Rather, it identifies the various complexities with applying this literature to provide a monetized estimate of the passive use value effects of the CRSO EIS alternatives. In selecting an alternative, the effects on fish of each alternative were considered carefully in the context of all of the types of socioeconomic values (e.g., commercial and recreational fisheries, subsistence, passive use, etc.) This approach does not constitute disregarding the literature or the evidence of the magnitude of passive use values, as described in this comment.
3999	40	ttrue@earthjustice.org	Earthjustice	The agencies fourth reason for disregarding the results from the 18 studies is that one study had too broad a focus. o [T]he study that most closely matches the policy context of an MO, the ECONorthwest lower Snake River dam removal study, presupposes that the dam breach will restore wild salmon. Apparently, the agencies felt that this studys use of the term, restore, was sufficiently offensive or inadequate in some unexplained way for them to disregard completely the studys findings regarding passive use value. Again, however, the agencies offer no scientific, analytical support for their decision. And they mischaracterize the study as based on a single survey of passive use value when, in fact, the study considered the estimates of value derived from multiple surveys and the value derived from survey cited by the agencies represents the lower range of those surveys in its analysis. Furthermore, the agencies do not provide any statistical assessment of the extent to which using the term affected the studys findings, if at all. Without such evidence, the study the agencies reject actually has far more scientific, analytical support than does the agencies arbitrary and unsupported decision to disregard those findings.	The ECONorthwest analysis and the EIS employ different analytical frameworks and rely on different findings with respect to the outcomes of breaching the four lower Snake River dams. First, the ECONorthwest report applies a cost-benefit analysis framework, emphasizing monetization of all categories of impacts. Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on fish are not quantified as monetized economic values does not mean that they were not considered in the context of the analysis. Second, the findings of the ECONorthwest report that the benefits outweigh the costs of breaching the dams rely on the implicit assumption that breaching would result in restoration of salmon populations. The fish effects analysis in Section 3.5 of the EIS does not find that Multiple Objective alternative 3 would result in recovery of salmon or steelhead populations or in restoring the populations to historical levels. Thus, the values presented in the ECONorthwest report should not be considered as representative of the benefits of MO3. However, the results from the ECONorthwest study contribute to the overarching conclusion of Section 3.15.2.2 that describes that the literature consistently demonstrates that people hold passive use values for salmon.
3999	41	ttrue@earthjustice.org	Earthjustice	The agencies fifth reason for disregarding the results from the 18 studies is their own unexplained judgment. o Best practices for benefit transfer identified in OMB Circular A-4 describe that meeting all criteria is difficult and that professional judgment is required in determining whether a particular transfer is too speculative... (OMB 2003, 26). Given the limitations of the existing literature, this EIS does not include a quantitative benefit transfer of passive use values. This statement means the agencies concluded that their professional judgment as to the relevance of the available information about passive use values described above is sufficient to Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 26 render entirely irrelevant all of the information and analysis of all the professional economists who prepared the 18 studies or provided peer-review approval for the studies. And, they provide no rational account or support for this decision. They never demonstrate that their professional training and experience are superior to those of the economists who completed the 18 studies. None of the 18 studies was completed by the co-lead agencies. They never demonstrate why it would be reasonable for a member of public, decision-maker, or court to conclude that their using zero as the passive use value throughout the DEIS provides a reasonable, accurate representation of the full socioeconomic consequences from adopting any of the alternatives. Nor do they demonstrate why their using zero as the passive use value throughout the DEIS is consistent with their NEPA requirement to take a hard look at each alternatives effects.	Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the existing literature on passive use values is not used to estimate a quantitative passive use value effect does not indicate, as described in this comment, that the literature is "irrelevant" nor does the EIS make judgments about the expertise of the economists that developed the studies. In fact, the literature is presented for consideration in Section 3.15.2.2 due to its relevance to the EIS. However, this comment implies that unless the information on passive use is used to quantify a specific monetized value of the alternatives that it is not considered at all. This is not the case. The NEPA analysis framework does not require monetization (i.e., quantification) of all types of potential effects of the alternatives (see 40 C.F.R 1502.23). Many categories of impacts are described qualitatively or in various quantitative metrics. In selecting an alternative, the effects on fish of each alternative were considered carefully in the context of all of the types of socioeconomic values (e.g., commercial and recreational fisheries, subsistence, passive use, etc.). This approach does not constitute disregarding the literature and the evidence of the magnitude of passive use values, as described in this comment.
3999	42	ttrue@earthjustice.org	Earthjustice	5. The DEIS fails to show quantitative estimates of passive use values even though the supporting evidence is actually more reliable than the evidence it employs to show quantitative estimates of industrial benefits. The preceding section explains that the DEIS does not include quantitative estimates of passive use values in the descriptions of alternatives, comparison of the alternatives, and selection of the Preferred Alternative. It excludes quantitative estimates despite the existence of 18 studies designed and implemented expressly to estimate either the passive use value or the total economic value households assign to salmon populations. This failure to show any quantitative value means that, in effect, these sections of the DEIS treat passive uses as if their value is zero. These sections do, however, contain many quantitative estimates of value for the benefits the alternatives, especially those other than MO3, would provide the irrigation, navigation, and hydropower industries. A comparison of the information available to the agencies for passive use values and the information available for industrial values shows a significant and unexplained difference in the reliability of the former (passive use data and analyses) as compared to the latter. For example, the agencies had access to 18 studies that provide quantitative estimates of passive use values. These studies were completed by professional economists and satisfied widely accepted analytical standards. They report both the expected passive use value and the statistical confidence interval surrounding this amount. A comparison of studies completed in different years indicates that the passive use values Americans assign to salmon and other atrisk species is increasing. In stark contrast, the agencies estimated the cost to irrigators of implementing MO3 based on conversations with several extension agents. The agencies do not report that these individuals conducted any statistical analysis and employed any data, or, instead, just communicated opinions based on hunch and intuition. The agencies estimate of these costs does not include any description of the statistical confidence interval surrounding this amount.	This comment correctly summarizes the EIS assessment of the existing literature describing passive use values for salmon. These studies are presented in the EIS due to their relevance. As described in Section 3.15.2.2, the co-lead agencies conclude that the literature consistently identifies that the general public holds value for the salmon beyond any direct or indirect use (e.g., fishing, wildlife view, subsistence, etc.). Consistent with NEPA analysis frameworks (see 40 C.F.R. 1502.23), the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on passive use for fish are not quantified as monetized economic values does not mean that they were not considered in the context of the analysis or are implicitly assigned a value of zero.
3999	43	ttrue@earthjustice.org	Earthjustice	The authors of the 18 studies reported their findings with attention to the level of precision supported by the underlying data and statistical analysis. Their estimates of passive use value, therefore, show 12 decimal places. The agencies estimates of industrial values, however, show no regard for concerns about precision. In their Table 4-6. Summary of M&I Water Supply Modification Construction Costs, they estimate irrigators costs under MO3 to 8 decimal places. This detail implies that the agencies (or the several extension agents) have enough knowledge about each of the 47,926 allegedly affected acres to determine that the total annualized cost will be at least $4,894,782.68, or $102.13209281 per acre. This supposed level of detail contradicts all applicable standards of socioeconomic analysisthe agencies can know the costs to this level of precision only if they have measured them with microscopes. The Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 27 assertion of this level of precision calls into question the agencies entire description of the irrigation costs from MO3. Similar levels of precision elsewhere in the DEIS call into question the reliability and rationality of the agencies estimates of other benefits and costs for irrigation, navigation, and hydropower. The agencies discredited some of the 18 studies of passive use values because they were conducted 20-30 years agocalling into question whether they accurately reflect current values held by the public. As explained above, evidence indicates that the passive use values held by the public for salmon and other at-risk species have been increasing, so that it appears the estimates from past studies likely understate the current values (or future values). The agencies dismissal of passive use value estimates from studies conducted 20-30 years ago contrasts with their willingness to base their estimates of irrigators costs under MO3 on the assumption that these estimates accurately reflect conditions extending 50 years into the future. Moreover, the agencies repeatedly relied on data and calculations from old studies to provide quantitative estimates in the DEIS of variables other than passive use value. For example, the agencies took specific estimates, from the Corps 2002 report, of recreation-visitor days in 1998 and scaled them upward by growth in population to estimate the	While the numbers quoted in the comment could not be located in the CRSO EIS, attempts were made to use a consistent rounding approach in the water supply section for the Final EIS. This comment correctly summarizes the EIS assessment of the existing literature describing passive use values for salmon. These studies are presented in the EIS due to their relevance. As described in Section 3.15.2.2, the co-lead agencies conclude that the literature consistently identifies that the general public holds value for the salmon beyond any direct or indirect use (e.g., fishing, wildlife view, subsistence, etc.). That these studies are presented in the EIS indicates that they were not "dismissed" but provided for consideration, both describing their relevance and their limitations with respect specifically to quantifying the passive use value effects of the CRSO EIS alternatives. Not using the studies specifically to monetize (i.e., quantify) passive use value effects of the CRSO EIS alternatives does not constitute "discrediting" the studies. The EIS describes that the studies conducted 20 to 30 years ago rely on outdated survey methodologies and baseline conditions for salmon populations. Although there is reason to believe that passive use values by people have been increasing over time, the older studies do not apply the state of science methods for eliciting information on these values. This discussion in the EIS does not state that the passive use values literature is overestimating (or underestimating) values people hold for salmon. Rather, it identifies the various complexities with applying this literature to provide a monetized estimate (i.e., quantification) of the passive use value effects of the CRSO EIS alternatives. Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on passive use for fish are not quantified as monetized economic values does not mean that they were not considered in the context of the analysis or are implicitly assigned a value of zero.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				current visitor days [p. 3-1215 - 1217]. But they dont explain why they did not employ a similar approach to scale-upward the passive use value estimates from past studies. They also use estimates from the Corps 2002 study to quantify the increase in the available spawning habitat for fall-run Chinook [p. 3- 566], habitat losses [p. 3-749] and the ammonia eluriate concentrations for the four Lower Snake River reservoirs [p. 3-271] under MO3. To develop estimates of the infrastructure costs that would result under MO3, the agencies relied on estimates not just from the Corps 2002 but also an earlier study completed in 1999 [p. 3-1137]. These, and numerous other examples where the agencies employed data from studies completed in past decades to estimate the current or future value of other variables demonstrate the arbitrary nature of their decision not to employ past studies to estimate the current and future values for passive uses. This inconsistency also shows that the agencies provided no scientific, analytical explanation for why members of the public, decision-makers, or anyone else should assign any credibility to their estimates.44	
3999	44	ttrue@earthjustice.org	Earthjustice	6. The DEIS fails to provide information to show that the Preferred Alternative will yield socioeconomic benefits from healthy and resilient ecosystems and does not show that the Preferred Alternative will provide socioeconomic benefits that would be equal to or exceed those of Alternative MO3. The PR&G require the co-lead agencies to protect and restore the functions of ecosystems and mitigate any unavoidable damage to these natural systems. This requirement represents priorities for the ecosystems, themselves, but also a recognition that the short-and long-run socioeconomic well-being of local, regional, and national communities depends on healthy, resilient ecosystems. Implementation of the Preferred Alternative will not yield a healthy and resilient ecosystem in for the Columbia and Snake Rivers.45 Instead, it calls for repeated actionsinvestments in dredging, levees, locks, etc.that will continue the current trajectory of ecosystem degradation and place the ecosystem at greater risk than other alternatives like MO3. Continuing these conditions in the ecosystem may have negative repercussions in other ecosystems. For example, failure to restore a healthy and resilient ecosystem in the Lower Snake River likely will reduce the numbers and reliability of anadromous fish downstream and in the ocean, and further compromise the health and resilience of populations of orca and other species 44 The agencies recognize some uncertainty, insofar as they provide estimates representing the lower and upper bound of the potential costs. In each instance, though, they show estimates with an unbelievable level of precision. 45 For more information about these issues see other sections of these comments Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 28 dependent on these fish. Failure to restore a healthy and resilient ecosystem in the Lower Snake River also likely will reduce the numbers and reliability of anadromous fish upstream. The diminished supply of nutrients carried by adult fish from the ocean to upstream locations will directly deprive upstream ecosystems of these nutrients with broader negative effects on other fauna and flora. The DEIS does not discuss or disclose these additional costs of the preferred alternative or the comparative benefits of alternative MO3.	The PR&G is intended to provide objectives and guidance to Reclamation and the Corps for new water resource investments, which include both structural and nonstructural approaches to water resource projects, water supply problems, investments in restoration, as well as other water-related investments. If an agency is seeking authorization and appropriations from Congress to fund a federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. One of the goals of a PR&G analysis is to determine the economically justified alternative by conducting an economic cost benefit analysis, referred to as National Economic Development (NED) effects in the superseded P&Gs. In the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. CEQ NEPA regulations (40 CFR 1502.23) address the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. The commenter is correct that the PR&G suggests using an Ecosystem Services Approach, which is not a requirement under NEPA. However, changes in ecosystem functions and services were addressed in the appropriate section of the FEIS (for example, in water quality, water supply, air quality, recreation, etc.). As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the purpose and need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The co-lead agencies did not initiate this EIS as a restoration project (which would be a new study), nor are they required to restore a healthy and resilient ecosystem in the lower Snake River. The focus of the CRSO EIS was on CRS operations, maintenance and configuration of which congress has previously authorized and appropriated for the co-lead agencies to construct and manage. Under NEPA, the co-lead agencies are required to analyze a range of alternatives to meet the purpose and need for the action. The CRS is a complex system with multiple, sometimes competing, congressionally authorized purposes. The Purpose and Need Statement and the objectives developed for this EIS reflect these multiple purposes, as do the alternatives developed to meet them. The analysis of the multiple objective alternatives allowed the co-lead agencies to understand the effects of emphasizing some purposes differently over others in order to find while seeking the most acceptable balance for future operations and maintenance.
3999	45	ttrue@earthjustice.org	Earthjustice	Concerns about ecological health and resilience embrace not just the potential for an ecosystem to adapt to the small perturbations generally expected to occur in the future, but also the potential for seeing an ecosystem move beyond a tipping point that will cause it to shift to a new state. The DEIS fails to exhibit any attention to, or even recognition of, the potential for ecosystemswithin the Lower Snake River Basin, upstream, downstream, or in the oceanto experience a tipping point. By failing to recognize, describe, and respond to potential threats and risks to ecosystem health and resilience, the DEIS fails to inform the public and decision-makers of some of the most significant socioeconomic impacts associated with the choice among the alternatives it considers. The absence of a complete, transparent and objective socioeconomic assessment of the alternatives considered in the DEIS, including but not limited to the Preferred Alternative indicates that selection of this alternative was arbitrary.	Selection of the Preferred Alternative was not arbitrary: it was based on the extensive analysis provided in the Draft EIS. Chapter 7 outlines the rationale for developing this alternative in detail. NEPA does not require agencies to define ecological tipping points, nor does NEPA require agencies to address potential threats and risks to ecosystem health and resilience. NEPA does require agencies to analyze the effects of potential actions and made this analysis available to the public and decision makers. The co-lead agencies provided a robust analysis of socioeconomic effects in the EIS. As required by NEPA, the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapters 3, 4, 5, 6 and 7; summarized by resource and alternative in Table 3-1, and once again presented for comparison in Tables 7-1 and 7-55. Socioeconomic analysis are discussed under numerous resources: Power Generation and Transmission; Air Quality and Green House Gasses; Navigation and Transportation; Recreation; Water Supply; Fisheries and Passive Use; Environmental Justice; and Implementation and System Cost Analysis. The EIS considered the effects of all of the actions and measures in the alternatives for a multitude of ecological resources, such as water quality and fish, as time progresses from implementation into the future. There are many ecosystem and individual resource effects that occur outside the operation and maintenance of the CRS. Salmon and steelhead and other resources have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat (see Chapters 6 and 7 for additional information). The co-lead agencies analyzed the effects of the operation, maintenance, and configuration of the CRS projects on resources affected by the CRS. The co-lead agencies also looked at the cumulative effects of past, present, and reasonably foreseeable future actions and trends in Chapter 6 (Cumulative Effects) and Chapter 7 (Preferred Alternative), of the EIS. Further, Chapter 4 (Climate) provides an overview of the project changes in future regional climate and discusses how these changes would affect each of the resources under each alternative.
3999	46	ttrue@earthjustice.org	Earthjustice	7. The DEIS overstates negative regional economic effects. In Annex C of Appendix Q, the DEIS shows the agencies estimates of each alternatives effects on jobs, labor income, and sales. The estimates come from applying an input-output model to the estimated annual implementation and system costs for each alternative. This approach suffers from two flaws that render the findings incomplete and misleading. The first flaw comes from the agencies application of the input-output model. Embedded in the model are assumptions that fail to represent economic realities. Most notably, the model assumes that, once the agencies spend money and create new jobs, they will be filled by workers who otherwise would be unemployed. Conversely, if an alternative results in the cessation of a job, the model assumes the displaced worker will remain unemployed forever. Both of these assumptions are at odds with the available evidence of how the economy works. By using the model without accounting for these inaccurate assumptions, the agencies overstate the number of new jobs (and the labor income and output) from an increase in their spending, failing to recognize that some of the workers who fill the new jobs will do so by the leaving jobs where they are already employed, so the net increase in employment (and labor income and output) will be smaller than the estimate of gross impact coming from the model. And, if an alternative results in workers losing their jobs, some or all will find replacement jobs, sooner or later, at wage-levels that are higher or lower, but the agencies approach does not account for this economic reality either. There are many well-accepted approaches in the field of economics to addressing these two issues but they agencies employed none of them.	The regional economic effects evaluation uses IMPLAN, a standard economic impact analysis data and software system that uses input-output techniques to estimate direct and secondary jobs and income associated with changes in final demand. IMPLAN is widely used by academics, industry, and government agencies. The evaluation does not presume that new jobs would be created or would no longer exist; the evaluation describes how many jobs are supported by the level of Federal and contractor expenditures under each of the alternatives, based on current ratios and multipliers effects in the economy for a given industry or government sectors. For example, a higher level of expenditures would support a greater number of jobs, in general.
3999	47	ttrue@earthjustice.org	Earthjustice	The second flaw comes from the agencies focus on describing the economic effects from their own expenditures. This focus ignores the economic effects likely to result from changes in the ecosystem. Most notably, it ignores the potential increases in ecosystem-related jobs, labor income, and output that likely would follow from improvements in salmon populations, and other indicators of ecosystem health resulting from implementation of MO3. This excerpt and the related figure, which are from a report prepared for agencies in the Department of Interior, Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 29 summarizes the importance of the relationship between ecosystem health and economic activity:46 o Restoration activities transform degraded ecosystems into restored ecosystems; figure 1 describes the potential economic effects of this transformation. Ecosystem restoration may also result in long-term economic impacts if the restored ecosystems support improved productivity of agriculture and forestry or increase recreation, tourism, or other business activity. Beyond generating economic activity, restored ecosystems provide substantial economic values through improved ecosystem services that directly and indirectly impact human welfare. Economic value is a measure of the benefits enjoyed by individuals or society from the use or existence of a good or service, and is a distinctly different measure than economic impact. Restoration projects can increase economic value by restoring and maintaining important habitat for fish and wildlife species, improving water quality, and reducing fire and flood risk. The DEIS ignores the Long-term economic impacts and Economic value shown in the figure. Other economists also have described the potential economic effects of ecosystem improvements, and the DEIS ignores their findings also.47 In sum, the agencies failed to provide accurate, reliable estimates of the effects likely to result from their expenditures under each alternative and to account for the socioeconomic effects of ecosystem improvements resulting from implementation of MO3. 46 Cullinane Thomas, C., C. Huber, K. Skrabis, and J. Sidon. 2016. Estimating the economic impacts of ecosystem restorationmethods and case studies. 47 See, for example, Headwaters Economics. 2020. Broader economic impact of national parks. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 30	The social welfare effects are not a measurement of agency expenditures, as the commenter states, but rather reflect the social welfare effect that could occur from change in consumer and/or producer surplus. For each economic activity addressed in the EIS, the analysis assesses potential effects of MOs on social welfare, regional economic spending patterns, as well as other social effects. Social welfare effects are changes to the economic value of the national output of goods and services. For example, economic value described in the navigation analysis includes producer surplus gained from commercial navigation activities, as well as the value, or the improved well-being, gleaned by tourists and recreationists associated with cruise line visits (referred to by economists as consumer surplus or net economic value).
3999	48	ttrue@earthjustice.org	Earthjustice	III. Socioeconomic Elements of the DEIS Show that Reclamation Failed to Apply the Department of the Interiors Agency-Specific Procedures for implementing the Principles, Requirements, and Guidelines On November 15, 2015, the Department of the Interior published its commitment to satisfy the standards and requirements of the PR&G, as well as the procedures it believed necessary for its bureausincluding Reclamationto do so.48 These procedures confirm what the other co-lead agencies must do to comply with WRDA and the PR&G. A. Reclamations failure to satisfy analytical and decision-making requirements Table 1 shows some of the general, analytical and decision-making requirements the Department of Interior has adopted and Reclamation should have employed in the DEIS. Table 1. Requirements for Implementing the PR&G, Expressed in the Department of Interiors Agency-Specific Procedures Analytical and Decision-Making Requirements The WRDA specifies that Federal water resources investments shall reflect national priorities, encourage economic development, and protect the environment by: 1) Seeking to maximize sustainable economic development; 2) Seeking to avoid the unwise use of floodplains and flood-prone areas and minimizing adverse impacts and vulnerabilities in any case in which a floodplain of flood-prone area must be used; and; 3) Protecting and restoring the functions of natural systems and mitigating any unavoidable damage to natural systems. The objectives identified above should be embodied in the Departments new water resource investments, which include both structural and non-structural approaches to water supply problems, investments in restoration, as well as other water-related investments. Two key concepts in the PR&G are Federal investment and public benefit.[footnote omitted] The term Federal investment is defined as (IG, p. 4): ...those [investments] that by purpose, either directly or indirectly, affect water quality or water quantity, including ecosystem restoration or land management	The co-lead agencies adhere to the Principles, Requirements, and Guidelines (PR&G) and the Water Development Resources Act (WDRA) by fully analyzing the effects of the alternatives, weighing the potential effects of the proposed alternatives, and considering the full economic effects of the alternatives. The NEPA process provides the analytical and decision-making standards of the PR&G. The co-lead agencies describe the effects to the natural environment, including floodplains and flood-prone areas, socioeconomic effects, and provide mitigation and adaptive management to offset the adverse environmental impacts. The PR&G is a statement of policy, not regulation, and are intended to articulate expectations for the internal management of the government. It does not impose any legally binding requirements on Federal agencies. NEPA however, does guide future decisions and would be binding. See response to Comment 3999-44.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				activities. The total level of a given investment shall be determined on a present value basis over the life of the Federal investment. Public benefits encompass environmental, economic, and social goals, include monetary and non- monetary effects and allow for the inclusion of quantified and unquantified measures. The planning process will ensure that plan formulation, evaluation, and implementation of agency projects and programs adequately incorporate the Guiding Principles identified in the Principles and Requirements. To encourage efficiencies and foster understanding, bureaus and offices generally should integrate PR&G analysis into NEPA analysis for a proposed action by presenting the PR&G analysis in the NEPA document. A recommended plan for a Federal water resource investment that does not maximize net public benefits requires a Secretarial Exception. Comparing the DEIS with Table 1 reveals that Reclamation (and its co-lead agencies) systemically failed to satisfy these analytical and decision-making requirements in at least these ways: 48 Department of the Interior. 2015. Agency specific procedures for implementing the Council on Environmental Qualitys Principles, Requirements, and Guidelines for Water and Land Related Resources Implementation Studies. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 31 1. Reclamation failed to ensure that the DEIS accurately reflects national priorities, encourages economic development, and protects the environment, as required by WRDA. The WRDA specifies that Federal water resources investments shall (1) seek to maximize sustainable economic development; (2) seek to avoid the unwise use of floodplains and floodprone areas and minimize adverse impacts and vulnerabilities in any case in which a floodplain of flood-prone area must be used; and; (3) protect and restore the functions of natural systems and mitigating any unavoidable damage to natural systems. The DEIS does not acknowledge these standards and requirements and does not satisfy them for reasons already discussed and discussed further below.	
3999	49	ttrue@earthjustice.org	Earthjustice	2. Reclamation failed to describe pubic benefits that encompass environmental, economic, and social goals, include monetary and non- monetary effects and allow for the inclusion of quantified and unquantified measures. This failure applies especially to the potential public benefits from breaching the Lower Snake River dams, in Alternative 3. It also applies to the agencies selection of their Preferred Alternative. In CHAPTER 7 PREFERRED ALTERNATIVE, the agencies emphasize that they selected this alternative by balancing multiple purposes, and consider[ing] the benefits, environmental consequences, tradeoffs, and costs of alternatives. But these statements beg the questions: How did they determine the balance, and how did they consider the benefits, environmental consequences, tradeoffs, and costs, if the DEIS does not set forth, fully and objectively, the socioeconomic value of the environmental consequences, never describes the public benefits, and never weighs socioeconomic costs against the socioeconomic benefits? The absence of a detailed, complete socioeconomic analysis, as required by NEPA and the PR&G suggests that the agencies did the balancing and considering in an arbitrary, manner informed only by the decision-makers incomplete, monetary economic perceptions.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies adhere to the Principles, Requirements, and Guidelines (PR&G) and the Water Development Resources Act (WDRA) by fully analyzing the effects of the alternatives, weighing the potential effects of the proposed alternatives, and considering the full economic effects of the alternatives. The NEPA process provides the analytical and decision-making standards of the PR&G. The co-lead agencies describe the effects to the natural environment, including floodplains and flood-prone areas, socioeconomic effects, and provide mitigation and adaptive management to offset the adverse environmental impacts. The PR&G is a statement of policy, not regulation, and are intended to articulate expectations for the internal management of the government. It does not impose any legally binding requirements on Federal agencies. Agencies apply the PR&G when conducting new analysis for new projects before seeking congressional authorization. NEPA however, does guide future decisions and would be binding. The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish a framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. A Preferred Alternative was developed that meets the Purpose and Need Statement as well as certain objectives included in the EIS. Quantitative evaluations were conducted to determine the effects of each of the alternatives when appropriate. In instances where quantitative evaluations were not appropriate or possible, qualitative discussions are included to describe the effects of each alternative. The evaluations are clear, transparent, and repeatable based on high quality information. Regarding the PR&G requirements, if an agency is seeking authorization and appropriations from Congress to fund a federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. One of the goals of a PR&G analysis is to determine the economically justified alternative by conducting an economic cost benefit analysis, referred to as National Economic Development (NED) effects in the superseded P&Gs. In the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. CEQ NEPA regulations (40 CFR 1502.23) address the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. Further there is no policy or law that requires the use of the PR&Gs.
3999	50	ttrue@earthjustice.org	Earthjustice	3. Reclamation fails to show the full Federal investment of each alternative, including the Preferred Alternative. The DEIS fails to completely and adequately comply with explicitly stipulated requirements for describing the commitment of Federal assets, i.e., the Federal investment, that will follow from a decision to implement the Preferred Alternative. The DEIS similarly fails to completely and adequately describe the Federal investment for the other alternatives. For example, the agencies assert (p. 7-3) that, in selecting the Preferred Alternative, The co-lead agencies considered the ability of each alternative to comply with all Federal laws and regulation. This statement is inaccurate. As the DEIS, itself, shows, the co-lead agencies never presented any analysis to comply with WRDA, never presented any analysis to satisfy the standards and requirements established by the PR&G, never complied with the analytical requirements of Executive Order 12866 and OMB Circular A-4,49 and never took the hard look at the socioeconomic impacts of each alternative needed to comply with NEPA. The PR&G require the co-lead agencies to estimate the full value of the Federal investment that would be required with a decision to implement each alternative. Interiors Procedures define Federal investment as those [investments] that by purpose, either directly or indirectly, affect water quality or water quantity, including ecosystem restoration or land management activities. Some of this Federal investment comes from the commitment of ecosystem resources, e.g., wetlands, cold water temperatures, and fish. Others involve the commitment of recreational resources, e.g., opportunities for rafting on a free-flowing Lower Snake River. And yet others include the appropriation of cultural resources, such as sites, fish 49 Executive Order 12866. 1993. Regulatory planning and review; Office of Management and Budget. 2003. Circular A-4: regulatory analysis. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 32 populations, and river conditions important for Tribal ceremonies, fishing, and other activities. The DEIS does not describe or provide an estimate of the value of these elements of the Federal investment embedded in the Preferred Alternative or other alternatives that would keep the four Lower Snake River dams in place. Some of the Federal investment in the preferred Alternative and other alternatives that would keep the dams in places involves the expenditure of taxpayers money to operate, maintain, and rehabilitate the four Lower Snake River dams, hydropower generators and related equipment, and the navigation channel. The co-lead agencies did not include in the DEIS all the relevant, readily available information regarding these costs. For example, they fail to report, analyze, and incorporate into their decisions the findings of a 2015 estimate of the costs associated with (1) improving fish passage at the four dams, (2) O&M costs, including minor repairs to the four dams and O&M costs for system improvements, (3) turbine rehabilitation costs, (4) costs to mitigate for the loss of salmon and other fish, (5) dredging costs for rehabilitating the navigation system and meeting flow-conveyance targets, and O&M costs plus minor repairs for power generation system.50 The analysis concluded that, using 2015 as the analytical base and a discount rate of 6.88 percent per year, the average annual cost of keeping the four dams in place would cost taxpayers $313 million per year. This amount rises to more than $435 million per year using a lower discount rate, 4.75 percent per year to reflect the costs of capital in 2015. In todays economic environment, with the Federal Reserve Bank making money available with a cost of capital approximating zero, the annual cost would be much higher still. Thus, to calculate the Federal investment required with implementation of the Preferred Alternative, the co-lead agencies should have included the cash expenditures for any new infrastructure, the expenditures to operate and maintain and rehabilitate the infrastructure, the opportunity-cost value of the existing human-built assets (dams and other infrastructure), as well as opportunity-cost value of the continuing commitment of ecosystem assets.51 In other words, the agencies should have shown the total amount of Federal investmentcash, infrastructure, land, ecological functions, and equipmentthat this alternative will commit to continued operation of the CRSO. Reclamation and its co-lead agencies did not comply with this requirement to fully describe the Federal investment embedded in each alternative, including the Preferred Alternative. Interiors Procedures also stipulate that The total level of a given investment shall be determined on a present value basis over the life of the Federal investment, Not just over an period of time that the agencies choose. In other words, where the DEIS shows a specific investment under the Preferred Alternative, it is not sufficient for the agencies to show just the initial amount of the Federal investment. Instead, the DEIS must show the continuing, annual Federal investments that will follow from this initial amount, throughout the lifetime of the initial investment, and then convert this stream of annual expenditures to an equivalent, single value, called the present value.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. The EIS does not employ a cost-benefit framework for decision-making. This is because, consistent with NEPA analysis framework (see 40 C.F.R. 1502.23), the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. Furthermore, the EIS evaluates the performance of the CRSO EIS alternatives with respect to multiple stated objectives, for example related to improving fish passage and survival, reliable power generation, and minimizing greenhouse gas emissions. Turbine replacement and other capital requirements to maintain the four lower Snake River projects are included in the cost analysis, as described in Section 3.19 and Appendix Q (see Section 4.2). Regarding the PR&G requirements, if an agency is seeking authorization and appropriations from Congress to fund a federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. One of the goals of a PR&G analysis is to determine the economically justified alternative by conducting an economic cost benefit analysis, referred to as National Economic Development (NED) effects in the superseded P&Gs. In the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. CEQ NEPA regulations (40 CFR 1502.23) address the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. The costs to implement the alternatives and operate the system are not an indication of the benefits that the system provides. The beneficial and adverse effects of the alternatives, including the No Action Alternative, are described in various sections in the EIS, including 3.5 (fish), 3.7 (power and transmission), 3.8 (air quality and greenhouse gases), 3.10 (navigation), 3.11 (recreation), 3.12 (water supply), 3.15 (fisheries and passive use), and others. The effects of MO3 on electricity rates are described in Section 3.7 and are not included in the cost estimates described in Section 3.19 and Appendix Q. Table 3-1 provides a summary of all of the effects on all resources, including beneficial and adverse effects. For example, beneficial effects under MO3 in Region C are described for anadromous fish, recreation, fisheries, and Tribal perspectives. Although an ecosystem services approach was not directly followed, ecosystem services were addressed in the appropriate resource section (for example, recreation, water quality, water supply, fisheries, etc.).
3999	51	ttrue@earthjustice.org	Earthjustice	Reclamation and its co-lead agencies fail to comply with this requirement. For example, they do not show the full Federal investmentcash, infrastructure, land, ecological functions, and equipmentthat will follow from a decision to implement the Preferred Alternative. 50 Waddell, J., and Laughy, L. 2015. The costs of keeping the four lower Snake River Dams: a reevaluation of the Lower Snake River Feasibility Report. 51 Opportunity-cost value means the forgone value of the assets used in their highest-value alternative use. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 33 These requirements have clear implications for the standards and requirements the agencies must satisfy when describing the Federal investment of each alternative. A decision to implement the Preferred Alternative, for example, would entail committinginvesting not just	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate section of the Final EIS (for example, in water quality, water supply, air quality, recreation, etc.). These results are described in Chapters 3, 4, 5, 6 and 7 as well as the appropriate appendices. As is common in NEPA analyses (see 40 C.F.R. 1502.23), the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. As described in Chapter 7 of the Final EIS, the Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective alternative 3, which includes the measure to

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the expenditures of taxpayers cash, but also the infrastructurethe physical assets associated with the Lower Snake River dams, as well as the ecosystem assetsincluding all of the forgone benefitsused in implementing the Preferred Alternative. That is, the DEIS should show the opportunity-cost value of all Federal assets. These costs include all types of valuable resources. Thus, when specifying the Federal investment for the Preferred Alternative, they must include the value of all the assetscash, infrastructure, ecosystems, fish, land, etc.that will not be available to the American public for other uses as a result of keeping in place the four Lower Snake River dams. The DEIS does not show the full opportunity costs of all Federal assets that would be invested under each alternative, including the Preferred Alternative. The DEIS further fails to satisfy the requirement to describe the full commitment of the Federal investment in the Preferred Alternative insofar as it does not fully describe the risks to fish and ecosystems that would accompany implementation of this alternative. The investment associated with these risks is separate from and in addition to the investment that results from forgoing the benefits associated with declining quantities of fish and other resources because the Preferred Alternative will keep the dams in place. This investment occurs insofar as the publics actions are constrained by the expectation that resourcescash, ecosystem services, etc.must be kept in reserve, in case it appears that the risks will materialize.52 By not fully describing these risks, the agencies fail to let the public and decision-makers know that, some time in the foreseeable future, there is a significant likelihood that the Federal investment will prove to be not just those things (cash, infrastructure, land, etc.) that the agencies included in their description of the Preferred Alternative, but also the widespread loss of ecosystem services, including fish, that result from the CRSOs interactions with changes in climate, historic depletion of fish populations, and others factors.	breach the four lower Snake River dams. However, the Preferred Alternative also meets other objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. Regarding the PR&G requirements, if an agency is seeking authorization and appropriations from Congress to fund a federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. Under the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. 40 CFR 1502.23 addresses the role of cost benefit analysis within the context of NEPA compliance. The first half of 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. Further there is no policy or law that requires the use of the PR&Gs. Subsequent studies, such as NEPA and feasibility studies, would be conducted prior to implementation.
3999	52	ttrue@earthjustice.org	Earthjustice	4. Reclamation failed to ensure that plan formulation, evaluation, and implementation of agency projects and programs included in the DEIS adequately incorporate the Guiding Principles identified in the Principles and Requirements The PR&G are absent from the DEIS. For example, the agencies do not include WRDA and the PR&G in their list (p. 5-2) of Federal laws, regulations, and Executive Orders they looked to for the requirements they had to satisfy when preparing the DEIS.53	Regarding the PR&G requirements, if an agency is seeking authorization and appropriations from Congress to fund a Federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. One of the goals of a PR&G analysis is to determine the economically justified alternative by conducting an economic cost benefit analysis, referred to as National Economic Development (NED) effects in the superseded P&Gs. Under the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. Measuring the social welfare effects, or NED effects, related to water supply would be time consuming and cannot be completed within the EIS imposed schedule. Section 1502.23 of the NEPA regulations (40 CFR 1502.23) addresses the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. Generally, the PR&Gs are intended as guidance for analyzing Federal investments. Further there is no policy or law that requires the use of the PR&Gs.
3999	53	ttrue@earthjustice.org	Earthjustice	5. Reclamation failed to declare that it will have to secure a Secretarial Exception before it can select a Preferred Alternative that does not maximize net public benefits. The DEIS fails to demonstrate that the Preferred Alternative will maximize net public benefits derived from the CRSO and the resources it affects. Relevant, readily available evidence, described above, suggests that an alternative that involves breaching the four Lower Snake 52 The risk-related element of the Federal investment is akin to the situation highlighted by the COVID-19 epidemic. Some state and local governments and corporations kept protective personal equipment in storage, to be made available if such a health threat should materialize. While in storage, these resources were not consumed, but also were not available for other uses. The co-lead agencies, and other entities, similarly should keep on hand cash, equipment, and ecosystem resources, such as undeveloped wetlands, and cold-water reserves, to be available should the outlook for salmon, other species, or entire ecosystems appear to be worse than expected. They should account for these investments, and for the extent to which the different alternatives increase or decrease the need for them. 53 This list includes only: Waters of the U.S. - Clean Water Act and EO 11990 Protection of Wetlands, Threatened and endangered species -Endangered Species Act and Lacey Act. This list also fails to include EO 12866, which governs regulatory economic analyses. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 34 River dams would yield higher net public benefits. The DEIS, however, does not explain these circumstance or demonstrate that Reclamation asked the Secretary for an exemption, allowing it to support selection of the Preferred Alternative rather than one that includes breaching. Indeed, the DEIS fails to even mention this requirement or to explain why it doesnt mention it.	Regarding the PR&G requirements, if an agency is seeking authorization and appropriations from Congress to fund a Federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. One of the goals of a PR&G analysis is to determine the economically justified alternative by conducting an economic cost benefit analysis, referred to as National Economic Development (NED) effects in the superseded P&Gs. Under the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. Measuring the social welfare effects, or NED effects, related to water supply would be time consuming and cannot be completed within the EIS imposed schedule. Section 1502.23 of the NEPA regulations (40 CFR 1502.23) addresses the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. Generally, the PR&Gs are intended as guidance for analyzing federal investments. Further there is no policy or law that requires the use of the PR&Gs.
3999	54	ttrue@earthjustice.org	Earthjustice	B. Reclamations failure to apply the required analytical framework Table 2 shows requirements Reclamation should have satisfied as it designed and implemented the analytical framework for the DEIS. Table 2. Requirements for Implementing the PR&G, Expressed in the Department of Interiors Agency-Specific Procedures Analytical Framework The PR&G require the use of an ecosystem services framework. Existing scoping processes may need to be adjusted to accommodate this framework. Such adjustments could include explicit identification of desired environmental conditions. Studies to decommission or remove existing dams would typically require the same level of analysis required for justifying construction of a facility. A summary of the specific economic, environmental, and social setting within the study area should cover the condition and functional relationships of affected resources; their development potentials and possible conflicts in producing affected ecosystem services; and the local situation with respect to investment, climate, markets, and basic economic productivity. Analysis to support the water resources alternatives should utilize the best available science, data, analytical techniques, procedures, models, and tools in ecology, hydrology, economics, engineering, biology, and other disciplines to the extent that sufficient funding is available. To the extent feasible, the effects of the alternatives should be quantified. Future land use patterns should be assessed and analyzed as part of the evaluation process and the best available data and forecast should be used to complete an analysis of these uncertain conditions. Future land use patterns should be evaluated based on historical trends and projections. When analyzing potential Federal water resource investments, areas of risk and uncertainty should be identified, described, quantified where possible, and considered as part of the decision. The first step to evaluate risk and uncertainty is to identify the nature of the harmful outcomes. The second step is to identify the likelihood of the outcome, either qualitatively or quantitatively. The third step is to identify a specific magnitude of the negative outcome relative to the proposed project objectives. An important aspect of evaluating ecosystem services is to identify those populations who will be impacted by a change in the resource. Comparing the DEIS with Table 2 reveals that Reclamation systemically failed to satisfy requirements for the agencies analytical framework in at least these ways: 1. Reclamation failed to use an ecosystem services framework. The scoping process did not use or explain an ecosystem services framework and, hence, neither does the DEIS. This failure can be seen, for example, from the documents table of contents, which does not list ecosystem services as a chapter or, more important, as the overriding organizational framework for the DEIS. The DEIS also does not include an explicit identification of desired environmental conditions. The agencies failure to begin the DEIS with an ecosystem services framework underlies the failure to fully describe the socioeconomic Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 35 importance of different ecosystem services, to analyze the socioeconomic consequences from each alternatives potential impacts on ecosystem services, or to show how the agencies factored these socioeconomic consequences into their selection of the Preferred Alternative.	The PR&G is intended to provide objectives and guidance to Reclamation for new water resource investments, which include both structural and nonstructural approaches to water supply problems, investments in restoration, as well as other water-related investments. If an agency is seeking authorization and appropriations from Congress to fund a federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. One of the goals of a PR&G analysis is to determine the economically justified alternative by conducting and economic cost benefit analysis, referred to as National Economic Development (NED) effects in the superseded P&G's. In the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. CEQ NEPA regulations (40 CFR 1502.23) address the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. Further there is no policy or law that requires Reclamation to use the PR&G. The commenter is correct that the PR&G suggests using an Ecosystem Services Approach, which is not a requirement under NEPA and because the co-lead agencies were not required to do a PR&G framework of analysis, ecosystem services analysis was not required. The co-lead agencies used the high quality information, data, analytical techniques, procedures, models, and tools to examine the alternatives. Potential outcomes (effects) of the alternatives were described fully in Chapters 3, 4, 5, 6, and 7, including effects to communities.
3999	55	ttrue@earthjustice.org	Earthjustice	2. Reclamation failed to provide the same level of analysis for breaching the Lower Snake River dams as it provided for constructing new facilities under the Preferred Alternative. The DEISs analysis of the Preferred Alternative is far more extensive than the analysis of Alternative 3, which included breaching the dams. Much of this disparity comes from the agencies determination that the Preferred Alternative would, but Alternative 3 would not, meet the purpose and need and objectives of the CRSO EIS that they identify, insofar as the former would extend the ability of the Corps and Reclamation to operate and maintain the 14 CRSO projects, and the latter calls for breaching the four Lower Snake River dams. As a consequence, the DEIS identifies, describes, and evaluates potential benefits the Preferred Alternative would provide to consumers of hydropower, irrigating farmers, the navigation industry, and the riverboat tourism industry. It does not, however, similarly identify, describe, and evaluate potential benefits that would result from the characteristics that distinguish Alternative 3 from the Preferred Alternative (and the others), including these: o Economic benefits to the American public as a whole and to specific groups from the higher likelihood of significant future increases in ecosystem reproduced fish. o Economic benefits to the American public as a whole and to specific groups from the opportunities for unimpounded river boating and related recreational activities. o Economic benefits from reductions in the risks that the existing infrastructure, programs, and operations create for the survival and recovery of at-risk species. o Economic benefits from reductions in the Federal investment and other socioeconomic savings to American taxpayers, the American public, and specific groups insofar as Alternative 3 would reduce the risks to salmon and other at-risk species and ecosystems from climate change and others factors interacting with the CRSO. o Economic benefits to electricity consumers from replacing the generating capacity of the four Snake River dams with capacity associated with solar, wind, batteries, and other clean energy technologies that are experiencing dramatic reductions in price.	The scope of the CRSO EIS covered eight objectives of which salmon, steelhead, and resident fish were three. In particular, the co-lead agencies developed measures to improve fish passage and fish flows, and reduce adverse impacts to spawning habitat. The potential economic effects from breaching of the lower Snake River dams are presented in the EIS, organized by resource area and type of economic impact, with additional details provided in resource specific appendices. Economic effects are described for changes to Power and Transmission (Section 3.7), Navigation and Transportation (Section 3.10), Water Supply (Section 3.12), and Recreation (Section 3.11). Potential economic impacts are evaluated for social welfare effects (national economic effect), regional economic effects, and other social effects. Additionally, the environmental impacts associated with increased emissions from shipping goods by rail or truck are evaluated and described in the Air Quality Section (Section 3.8), and increase health and safety concerns are described in the Navigation and Transportation Section for other social effects (Section 3.10.3.5). Breach of the dams has the potential to drop surface and groundwater levels up to 100 feet and it is not possible from an engineering or cost standpoint to replace the delivery mechanisms. Assumptions regarding the cost of reconfiguring water supply systems are discussed in the Water Supply Environmental Consequences Section for MO3 (Section 3.12.3.4, Region C). Effects to livelihoods are captured to the extent possible in the regional economic effects and other social effects sections that follow. Please see Section 3.12 and Appendix N for additional information. As described in Section 3.15.3.5, under MO3 commercial and ceremonial and subsistence fisheries targeting anadromous fish species across all regions may see major beneficial effects in the long term. Ceremonial and subsistence fisheries targeting residential species in Region C may see long term benefits, while those in Regions A may experience some moderate adverse effects.
3999	56	ttrue@earthjustice.org	Earthjustice	3. Reclamation failed to provide a thorough summary of the specific economic, environmental, and social setting within the study area. The DEIS does not provide a thorough summary of the functional relationships between specific ecosystem resources and local, regional, and national economies, or of how the CRSOs impacts on these resources affects these relationships and, hence the composition, strengths, and weaknesses of these economies and the social well-being of affected communities. For example, the DEIS does not provide a summary of the socioeconomic setting and its relationship to ecosystems, as evidenced by Table 3-1 Summary of Expected Effects by Multiple Objective Alternative. The table: o Describes no socioeconomic effects stemming from projected changes in Vegetation, Wetlands, Wildlife, and Floodplains. The discussion describes apparently serious changes in the resources. Under MO3, these resources along existing shorelines would either be lost or change how wildlife utilize the area, [h]owever new vegetation and habitat types along the new shoreline would be added associated with dam breaching, resulting in negligible beneficial effects and major negative	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establishes a framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead's numerous legal obligations. In terms of Table 3-1, it provides a summary of the findings from each resource section in turn. As the commenter notes, adverse effects to socioeconomic resources can occur associated with changes in natural resource conditions. This type of evaluation is conducted in the analysis, and the results are evaluated in associated socioeconomic sections. For example, the EIS recognizes that adverse effects to vegetation could result in adverse effects to socioeconomic resources, particularly recreational activities. Rather than identify these in the vegetation row in the table, these effects are identified and evaluation in the recreation section. There was an error in the Draft EIS that resulted in effects related to the fisheries and passive use

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				effects. These statements indicate that the co-lead agencies concluded that negligible beneficial effects and major negative effects have no socioeconomic consequences worth mentioning. o Describes no socioeconomic effects stemming from projected changes in Resident Fish. Under MO3, [b]reaching of the lower Snake River projects would have major long-term Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 36 beneficial effects to resident fish in the Snake River. The table does not, however, indicate that these major long-term beneficial effects to resident fish will lead to any socioeconomic consequences worth mentioning nor does it describe how these major benefits might affect other resources and hence have additional costs and/or benefits. o Has no section identifying socioeconomic effects as Expected Effects by Multiple Objective Alternative (from the tables title). In sharp contrast with the failure to mention socioeconomic effects associated with expected ecosystem changes, the table clearly describes socioeconomic effects from the alternatives effects on industries dependent on the CRSO. For example, the discussion of Power Generation and Transmission effects describes Long-term-major, adverse effects on power costs and rates under MO3. The discussion of Navigation and Transportation effects, says: MO3 would result in major adverse effects related to elimination of commercial navigation on the lower Snake River. Costs of shipping would increase 10% to 33% on average region-wide. Investments in infrastructure may be required. Cruise ship transit to the lower Snake River would not be possible. Additional dredging would be required in the McNary pool to access port facilities for 2 to 7 years. Reductions in regional economic benefits to port cities where cruise line expenditures would have occurred; redistribution of regional demands for material handlers. Even apart from whether this summary of effects on navigation and transportation is, itself, based on an accurate and objective analysis, the failure to incorporate socioeconomic effects in their description and evaluation of the Expected Effects of the alternatives disregards a large body of research on the socioeconomic significance of ecosystem impacts. Some of this research focuses on the cultural values of ecosystem services,54 the socioeconomic importance of recreational fishing,55 and the overall socioeconomic value of ecosystem resources.56 Other research focuses on how ecosystem resources interact with local economies.57 This research addresses, for example, relationships between the supply of natural resource amenities, such as free-flowing rivers and fishing opportunities, and indicators of economic well-being-job growth, household income, etc.in nearby communities.58 By not incorporating these research findings into the DEIS, Reclamation and the other co-lead agencies failed to satisfy not just the PR&G requirement to provide a thorough summary of the specific economic, environmental, and social setting within the study area, but also the NEPA requirement to take a hard look at all the expected effects associated with each alternative.	section of the analysis not being included in the table and the table has been updated for the Final EIS. This led many commenters to conclude that they were not considered. However, these effects are discussed in Section 3.15 of the EIS, and are now included in Table 3-1. This change, along with a number of other clarifications and improvements, have been made to in the Final EIS.
3999	57	ttrue@earthjustice.org	Earthjustice	4. Reclamation failed to utilize the best available science, data, analytical techniques, procedures, models, and tools in ecology, hydrology, economics, engineering, biology, and other disciplines. This failure is widespread within the DEIS. For example, the document fails to include the best available science, data, analytical techniques, models, and tools to describe and evaluate the non-monetized public benefits from actions that would improve ecosystem health, strengthen connections between the ecosystems and Tribes, and provide passive-use benefits to Americans 54 See, for example, Chan, K.M.A., T. Satterfield, and J. Goldstein. 2012. Rethinking ecosystem services to better address and navigate cultural values. 55 See, for example, Rosenberger, R.S.; E.M. White, J.D. Kline, and C. Cvitanovich. 2017. Recreation economic values for estimating outdoor recreation economic benefits from the National Forest System; Southwick Associates, Inc. 2009. Potential economics contributions of Spring and Summer Chinook had SAFE for Salmon been in effect. 56 See, for example, Flores, L., et al. 2017. The value of natural capital in the Columbia River Basin: a comprehensive analysis. 57 See , for example, the data available at the interactive website, Headwaters Economics. 58 See, for example, U.S. Bureau of Economic Analysis. 2019. Outdoor recreation satellite account, U.S. and prototype for states, 2017; Headwaters Economics. 2019. The outdoor recreation economy by state; Earth Economics. 2017. The value of natural capital in the Columbia River Basin: a comprehensive analysis; Hill, E., J. Bergstrom, H.K. Cordell, and J.M. Bowker. 2009. Natural resource amenity service values and impacts in the U.S. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 37 near and far. The DEIS also fails to quantify, to the extent possible, not just these benefits but it also fails to describe and quantify the socioeconomic risks to the limited range of benefits it ascribes to the Preferred Alternative that will come from trends and evolving market conditions affecting future agricultural output and the demand for navigation, competition to hydropower from solar/wind/energy-storage resources, and threats to anadromous fish populations from climate change and other factors.	The co-lead agencies used current, high quality information and in the analysis of the CRSO EIS. Quantitative evaluations were conducted to determine the effects of each of the alternatives when appropriate. In instances where quantitative evaluations were not appropriate or possible, qualitative discussions are included to describe the effects of each alternative. The socioeconomic analysis for the EIS was carefully performed and considered the most relevant information in the timeline provided for the work for the subjects of the analysis. The approach, analysis, and results were thoroughly reviewed by external reviewers, resource managers in the region, and the cooperating agencies. The evaluations are clear, transparent, and repeatable based on high quality information. The beneficial and adverse effects of the alternatives, including the No Action Alternative, are described in various sections in the EIS, including 3.5 (fish), 3.7 (power and transmission), 3.8 (air quality and greenhouse gases), 3.10 (navigation), 3.11 (recreation), 3.12 (water supply), 3.15 (fisheries and passive use), and others. Although an ecosystem services approach was not directly followed, ecosystem services were addressed in the appropriate resource section (for example, recreation, water quality, water supply, fisheries, etc.). Quantitative evaluations were conducted to determine the effects of each of the alternatives when appropriate. In instances where quantitative evaluations were not appropriate or possible, qualitative discussions are included to describe the effects of each alternative. Evolving market trends are discussed in the various Chapter 3 sections and carried through to Chapter 7 where appropriate. Further, the cumulative impacts analysis in Chapter 6 and Chapter 7 accounts for the effects of the alternatives when combined with past, present, and reasonably foreseeable future actions and trends. The socioeconomic impacts are addressed qualitatively and quantitatively in Chapter 6 and Chapter 7 where appropriate.
3999	58	ttrue@earthjustice.org	Earthjustice	5. Reclamation failed to assess and analyze future land use patterns as part of the evaluation process and failed to use the best available data and forecast to complete an analysis of these uncertain conditions. For example, the DEIS fails to describe how future land uses might emerge with breaching of the Lower Snake River dams and the restoration of a free-flowing river. As a consequence, it is impossible, from a reading of the DEIS, for the public and decision-makers to appreciate how these changes in land use might vary from those likely to emerge from implementations of the Preferred Alternative.	Without knowing the state of the land beneath the current reservoirs or the recovery time it will take once the dams are breached, it is speculative to assess any potential benefits from these lands. If MO3 were selected as the Preferred Alternative, further evaluations, engineering plans, and studies under NEPA would be required along with congressional authorization and appropriations to assess the engineering requirements of the project and to potentially further refine and develop mitigation measures. These further evaluations could include a more detailed evaluation of real estate disposal actions, effects to land use, and other related topics.
3999	59	ttrue@earthjustice.org	Earthjustice	6. Reclamation failed to identify all relevant areas of risk and uncertainty associated with each alternative, and it failed to describe, quantify where possible, and consider these risks and uncertainties as part of the decision to select the Preferred Alternative. The DEIS does not fully identify (1) the nature of all the harmful outcomes that would result from implementation of the Preferred Alternative; (2) identify the likelihood of the outcome, either qualitatively or quantitatively; or (3) a specific magnitude of the negative outcome relative to the proposed project objectives. For example, it does not fully describe the harmful outcomes that would occur if implementation of this alternative, interacting with changes in climate and other factors resulted in severe stress to one or more ecosystems and/or allowed the continued decline towards extinction of one or more species. The DEIS also does not fully describe the harmful outcomes that would occur if change in climate and known and likely market conditions were to markedly reduce agricultural production and the demand for barge traffic dependent on the CRSO. Nor does the DEIS fully describe the harmful outcomes that would materialize if changes in the supply of electricity from solar/wind/energy-storage technologies were to reduce demand for hydropower from the CRSO or alter the markets in which it is sold in ways that alter or undermine its value.	The purpose of the EIS is to evaluate options for the operation and configuration of the 14 dams in the CRS. As required by NEPA, the co-leads evaluated the effects of the alternatives on many resources. The EIS included quantitative and qualitative data and described in detail potential effects to resources. Frequency, likelihood, and magnitude of effects were analyzed. Climate change was discussed in Chapters 4 and 7 in great detail and effects to socioeconomics were described in chapters 3, 4, 5, 6, and 7. The EIS also analyzes impacts to power generation and transmission, including the interaction of renewable resources in Section 3.7 and 7.7.9.
3999	60	ttrue@earthjustice.org	Earthjustice	7. Reclamation failed to identify those populations who will be impacted by a change in the resource The DEIS primarily describes populations that will benefit from continued provision of benefits afforded by the Preferred Alternative, e.g., agricultural interests and the recreational riverboat industry. It fails to describe fully the many populations who would benefits from breaching the Lower Snake River dams, including: o Tribal members not living near the river o Americans who would enjoy an increase in passive-use value from restoration of the free-flowing river; improvements in the health of ecosystems adjacent to the freeflowing river, upstream and downstream, and marine; increases in non-hatchery populations of anadromous fish; and increases in food supplies for orcas o Recreational users of the ecosystems experiencing improvements in their health o Taxpayers who enjoy reduced risk of bearing costs to offset risks associated with implementation of the Preferred Alternative o Workers and business owners and communities experiencing the multiplier effects form the direct effects of implementing a river restoration alternative and the direct and indirect effects over time of a restored river. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 38	The comment is mistaken. The co-lead agencies have analyzed the effects of the dam breach measure across all affected resources, including tribal members, passive use values, riparian areas, river mechanics, recreation, resident and anadromous fish, and Southern Resident killer whales.
3999	61	ttrue@earthjustice.org	Earthjustice	C. Reclamations failure to satisfy requirements for defining, comparing, and evaluating alternatives Table 3 shows requirements Reclamation should have satisfied in the DEIS as it defined, compared, and evaluated alternatives. Table 3. Requirements for Implementing the PR&G, Expressed in the Department of Interiors Agency-Specific Procedures Defining, Comparing and Evaluating Alternatives When possible, alternatives should be developed to avoid the risk of adverse environmental impacts. In order to support full disclosure and promote transparency in the decision making process, the analysis of the final array of alternatives should include, at a minimum, the following: A discussion of: the primary purpose of the analysis; the geographic size of the study area; number of people potentially affected and anticipated degree of impact; the type of impacts; environmental justice considerations; and the size and location of communities potentially affected including the presence of Federally recognized tribes or tribal members; and the type of data and information available from collaboration, public involvement, and previous studies, if any. A without and a with-project alternative. Identification of an alternative that maximizes net public benefits. The PR&G also call for a transparent comparison of the effects of alternatives for their contribution to the Federal Objective and each of the Guiding Principles, using an ecosystem service approach and including a discussion of trade-offs in documentation provided in display and narrative form. Both quantified and unquantified effects should be considered as part of an ecosystem services analysis. Effects should be monetized to the greatest extent possible. [I]nvestments should maximize the present value of net public benefits. Net public benefits implies that the anticipated benefits will be presented relative to the costs associated with the accrual of those benefits. Net public benefits can include both quantified and non-quantified benefits. Public benefits should evaluate net changes in economic values associated with the market and nonmarket goods and services associated with alternative plans as well as changes in the economic values associated with external costs. Adverse effects should be valued at the opportunity costs of resources used in implementing a project, plan, or activity. These adverse effects could include: Implementation outlays, associated costs, the value of lost ecosystem services, and other direct costs. Comparing the DEIS with Table 3 reveals that Reclamation systemically and broadly failed in at least these ways to satisfy requirements for defining, comparing, and evaluating alternatives: 1. Reclamation failed to develop and fully analyze alternatives to avoid the risk of adverse environmental impacts that would result from implementation of the co-lead agencies current Preferred Alternative. Throughout the DEIS, Reclamation and the other co-lead agencies fail	The PR&G is intended to provide objectives and guidance to Reclamation for new water resource investments, which include both structural and nonstructural approaches to water supply problems, investments in restoration, as well as other water-related investments. If an agency is seeking authorization and appropriations from Congress to fund a federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. One of the goals of a PR&G analysis is to determine the economically justified alternative by conducting an economic cost benefit analysis, referred to as National Economic Development (NED) effects in the superseded P&Gs. In the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. CEQ NEPA regulations (40 CFR 1502.23) address the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. Further there is no policy or law that requires Reclamation to use of the PR&G framework. The commenter is correct that the PR&G suggests using an Ecosystem Services Approach, which is not a requirement under NEPA and because the co-lead agencies were not required to do a PR&G framework of analysis, ecosystem services analysis was not required. The co-lead agencies used the best available science, data, analytical techniques, procedures, models, and tools to examine the alternatives. Potential outcomes (impacts or effects) of the alternatives were described fully in Chapters 3, 4, 5, 6, and 7, including effects to communities.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				to provide full disclosure and promote transparency. For example, they fail to provide a thorough discussion of: the primary purpose of the analysis; the geographic size of the study area (their reasons for varying it and the effects of these changes); the number of people potentially affected and anticipated degree of impact; the type of impacts; environmental justice considerations; and the size and location of communities potentially affected including the presence of Federally recognized tribes or tribal members; and the type of data and information available from collaboration, public involvement, and previous studies, if any. For example: o Before developing and describing the Preferred Alternative, the agencies determined that Alternative 3 would not meet their declaration of purpose and need and objectives, Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 39 insofar as it would not extend the ability of the Corps and Reclamation to operate and maintain the four Lower Snake River dams. To the extent this led to an incomplete analysis of Alternative 3, the DEIS fails to fully and fairly identify, describe, and evaluate potential socioeconomic benefits that would result from the expected effects of the breaching on fish populations, wetlands, and other ecosystem resources. This failure contrasts sharply with their description of selected socioeconomic benefits they expect from the expected effects of the other alternatives on hydropower generation, navigation, and irrigation. o The DEIS looks outside the Columbia-Snake River Basin to examine the potential socioeconomic benefits from extending the production of hydropower from the four Lower Snake River dams. It does not similarly look outside the Basin to examine the potential socioeconomic costs stemming from the CRSOs impacts on ecosystems. That is, it fails to acknowledge that Americans living outside the Basin will realize benefits from MO3s positive impacts on ecosystems inside the Basin; that positive impacts will extend outside the Basin, e.g., to the Pacific Ocean and the Salish Sea; and that these more distant impacts also will yield socioeconomic benefits locally, regionally, and nationally. The DEIS never evaluates these broader ecosystem impacts, nor does it identify, describe, and evaluate the groups that would realize the benefits from them. o The failure to identify all the affected groups leaves the agencies unable to fully identify, describe, and evaluate the similarities and differences among the socioeconomic impacts on the different groups. Thus, the DEIS provides only a limited and incomplete examination of environmental-justice issues. It fails to describe how the different alternatives would affect minority populations, low-income populations, and Tribal members outside the Basin. Moreover, the DEIS looks for disproportionate impacts on these groups, and finds none, looking from the perspective of the agencies, themselves. For example, they conclude that, because groups of concern and the overall population would see the same changes in ecosystems, there would be no disparate impact on the groups of concern as a whole or individually. Looking from the perspective of these individual groups likely would yield the opposite conclusion. Some tribal members, for example, would see a reduction in salmon populations not just as a reduction in opportunities to catch fish, but also as further deterioration in cultural values resulting from the persistent effects of the CRSO on fish populations and overall ecosystems. o The failure to evaluate environmental justice effects from the perspective of those exposed to disparate impacts serves as proof that the agencies did too little to satisfy requirements for full and effective collaboration with groups of concern. Had they satisfied these requirements, they likely would have learned about the disparate socioeconomic effects of the CRSOs negative ecosystem impacts and included a true account of this information in the DEIS. o These comments describe information from previous studies that Reclamation and the other co-lead agencies failed to incorporate into the DEIS and provide citations to some of these studies to demonstrate that they were readily available to the agencies as they prepared the DEIS. Reclamation and the other co-lead agencies also fall short of requirements to fully analyze alternatives to avoid the risk of adverse environmental impacts insofar as they never identify or present an alternative that maximizes net public benefits. In sum, the DEIS fails to provide a full portrait of the socioeconomic requirements to implement each alternative or the full socioeconomic consequences from doing so. The DEIS fails even to mention public benefits of any type, for example, and especially the public benefits of ecosystem improvements. Other aspects of Reclamations failure to fully analyze alternatives to avoid the risk of adverse Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 40 environmental impacts, many previously mentioned, include: o Reclamation failed to provide a transparent comparison of the effects of alternatives for their contribution to the Federal Objective and each of the PR&Gs Guiding Principles, using an ecosystem service approach and including a discussion of trade-offs in documentation provided in display and narrative form. The DEIS fails to conduct an ecosystem-services analysis. It never provides a transparent comparison of monetized, quantified-but-not-monetized, and unquantified effects as part of an ecosystem-services analysis. The DEIS does not monetize effects to the greatest extent possible, using reliable data and other information. o Reclamation failed to evaluate public benefits, i.e., net changes in economic values associated with the market and nonmarket goods and services associated with alternative plans as well as changes in the economic values associated with external costs. The DEIS fails to identify, describe, and evaluate public benefits or public costs. It fails to describe changes in public benefits or public costs associated with each alternative, or to compare these changes across all the alternatives. o Reclamation failed to employ opportunity-cost values to determine the value of resources used in implementing each alternative. The DEIS does not fully identify, describe, and evaluate all the adverse effects of each alternative, nor does it compare the full costs across the alternatives. Nowhere does the DEIS provide a full account of the adverse effects of each alternative that includes: implementation outlays, associated costs, the value of lost ecosystem services, and other direct and indirect costs that will be incurred with the implementation of each alternative.	
3999	62	ttrue@earthjustice.org	Earthjustice	D. Reclamations failure to select a Preferred Alternative that will maximize net public benefits Table 4 shows requirements Reclamation should have satisfied in the DEIS to select a Preferred Alternative that will maximize net public benefits from the water and related land resources affected by the CRSO. Table 4. Requirements for Implementing the PR&G, Expressed in the Department of Interiors Agency-Specific Procedures Maximize Public Benefits The recommended plan must maximize net public benefits. Public benefits encompass environmental, economic, and social goals, include monetary and non-monetary effects and allow for the consideration of both quantified and unquantified measures. [I]f initial analysis indicates that qualitative benefits represent a significant proportion (20% - 50% or more) of the total project benefits, then additional analysis must be undertaken to quantify the non-quantified services. The PR&G require an analysis of water projects in terms of changes to ecosystem service flows over time. At a minimum, a qualitative discussion of the relative value of each alternative should be included. This discussion should include an assessment of all components of the total economic value, including both use and non-use value. As stated in the PR&G it is intended that Federal investments in water resources as a whole should maximize public benefits, with appropriate consideration of costs. Public benefits encompass environmental, economic, and social goals, include monetary and non-monetary effects and allow for the consideration of both quantified and unquantified measures. Non-use values reflect the common observation that people are willing to pay for resources, especially those Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 41 Table 4. Requirements for Implementing the PR&G, Expressed in the Department of Interiors Agency-Specific Procedures involving changes in unique natural resources, which they may never directly or indirectly use. Types of non-use values include: Existence values. Existence values are not derived from either direct or potential use and arises from the value placed on the intrinsic value of a resource apart from its use (e.g., individuals get pleasure from knowing a wilderness or animal and fish refugia exist). Bequest values. Bequest values arrive from and are based on the ideas of altruism. Bequest values are derived from individuals WTP for the pleasure they get from knowing that a resource is used by others, either currently or by future generations. Comparing the DEIS with Table 4 reveals that Reclamation, and the other co-lead agencies, systemically and broadly failed in at least three ways to satisfy requirements for maximizing public benefits derived from the water and related land resources affected by the CRSO: 1. Reclamation failed to select a proposed plan that will maximize net public benefits. To satisfy this requirement, Reclamation should have identified, described, and measured the net public benefits of each alternative and selected as the Preferred Alternative the one that promises the greatest net public benefits. In evaluating each alternatives net public benefits, Reclamation should have considered environmental, economic, and social goals, and included monetary and non-monetary effects and allowed for the consideration of both quantified and unquantified measures. Reclamation did not satisfy these requirements; the DEIS does not even exhibit an attempt to satisfy them, insofar as it ignores the concept of public benefits.	Under NEPA, the co-lead agencies are required to analyze a range of alternatives to meet the purpose and need of the Project. The CRS is a complex system with multiple, sometimes competing, congressionally authorized purposes. The Purpose and Need Statement and the objectives developed for this EIS reflect these multiple purposes, as do the alternatives developed to meet them. As required by NEPA, the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapters 3, 4, 5, 6 and 7; summarized by resource and alternative in Table 3-1, and once again presented for comparison in Tables 7-1 and 7-55. The PR&G is intended to provide objectives and guidance to Reclamation for new water resource investments, which include both structural and nonstructural approaches to water supply problems, investments in restoration, as well as other water-related investments. If an agency is seeking authorization and appropriations from Congress to fund a federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. One of the goals of a PR&G analysis is to determine the economically justified alternative by conducting an economic cost benefit analysis, referred to as National Economic Development (NED) effects in the superseded P&Gs. In the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. CEQ NEPA regulations (40 CFR 1502.23) address the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. Further there is no policy or law that requires Reclamation to use the PR&G framework. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
3999	63	ttrue@earthjustice.org	Earthjustice	2. Reclamation failed to give appropriate weight to public benefits that cant be fully quantified. The description and comparison of alternatives does not give equitable treatment to both quantifiable benefits and unquantifiable benefits, such as benefits to Tribal members and others who would derive benefits from breaching the Lower Snake River dams. This failure biases the DEIS against the interests of these groups and impedes the ability of the DEIS to fully represent the public benefits and costs of each alternative.	Under NEPA, the co-lead agencies are required to analyze a range of alternatives to meet the Purpose and Need Statement. The CRS is a complex system with multiple, sometimes competing, congressionally authorized purposes. . The co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as cooperating agencies, and over 30 of those invited agreed to participate. Staff from the Cooperating Agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation, maintenance and configuration of the dams in the CRS. The Preferred Alternative was chosen to meet the purpose and need to operate the system for the congressionally authorized multiple purposes, including fish, hydropower, and water supply, while minimizing adverse effect to biological and socioeconomic resources. The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. Consistent with NEPA analysis framework, the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. Effects to Environmental Justice communities, tribal interests, and tribal perspectives were included and considered throughout the process and informed decision making. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3, which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
3999	64	ttrue@earthjustice.org	Earthjustice	3. Reclamation failed to fully identify, describe, and evaluate non-use values. The DEIS does not provide a complete and appropriate consideration of existence values and bequest values associated with healthy ecosystems, ecosystem-produced fish, a freeflowing river, healthy populations of orcas, or a non-industrialized river.	Section 3.15.2.2 includes existing research on the passive use values for fish. This information is considered alongside the analysis of effects of the Multiple Objective alternatives on fish abundance (Sections 3.5 and 7.7.5). As described in Section 3.15.2.2, the economics literature includes research on passive use values for free-flowing rivers. These studies generally bundle the environmental changes associated with free-flowing rivers, including, for example, specifying effects on fish populations. Thus, passive use values for free-flowing rivers are not necessarily distinct from or additive with passive use values for the fish within these rivers. The overall health and condition of the Southern Resident killer whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. National Marine Fisheries Service (NMFS) and Washington Department of Fish and Wildlife (WDFW) have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NMFS and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. SRKW also are known to eat some steelhead, coho, and chum salmon, halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKW are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKW feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon Smolt-to-Adult return rates would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long-term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short-term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). Therefore, there may be short-term adverse effects to the SRKW population as the lower Snake River wild salmon populations adjust to changes associated with dam breaching. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKW. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA Biological Opinion 2020). The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. Additionally, MO3 is not likely to adversely affect the SRKW distinct population segment in the short-term analysis because increased hatchery production and the new trap and haul facility at McNary proposed for MO3 in Chapter 5 would address any potential short-term impacts.
3999	65	ttrue@earthjustice.org	Earthjustice	E. Reclamations failure to satisfy transparency requirements Table 5 shows transparency requirements Reclamation should have satisfied in the DEIS. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 42 Table 5. Requirements for Implementing the PR&G, Expressed in the Department of Interiors Agency-Specific Procedures Transparency To promote consistency across bureaus the following tables and information should be included in the analysis and in the documentation prepared for a decision process: Resource/ecosystem service tradeoff matrix. A matrix summarizing the tradeoffs, relative to the baseline, resource-by-resource. The matrix should be constructed using an ecosystem service framework, and include the following: o The annual and total estimated changes in the quantity and/or quality of each affected resource relative to the baseline over the period of analysis. The metrics used to evaluate changes in services and display tradeoffs must be clearly defined. o A quantitative measure of affected ecosystem services, even if not monetary, that goes beyond biophysical measures to address relevant social welfare. o Changes in estimated benefits should be quantified and monetized to the greatest extent feasible. The value of the project benefits should be presented on an annual basis over the period of analysis as well as in present value terms. Achievement of objectives table. A table indicating the extent to which the PR&G Guiding Principles have been achieved. Risk and uncertainty. The PR&G analysis must include a section documenting the basis for selecting a preferred alternative. This section must provide a benefit-cost analysis (conducted in accordance with the general Federal guidance for these types of analysis as well as this guidance) and a discussion about the extent to which the preferred alternative maximizes net public benefits. Comparing the DEIS with Table 5 reveals that Reclamation systemically and broadly failed in at least the following ways to satisfy requirements for presenting information and making decisions in a transparent manner: 1. Reclamation failed to present socioeconomic information in a fully transparent manner and, hence, to satisfy the District Courts Opinion and Order. The DEIS does not present a matrix summarizing the socioeconomic characteristics of each alternative, nor does it reveal the socioeconomic tradeoffs among them, relative to the baseline, resource-by-resource, using an ecosystem-service framework.59 It does not contain a table showing the extent to which the Preferred Alternative will achieve the PR&Gs Guiding Principles.60 It does not present a table describing the risk and uncertainty embedded in each alternative and how they differ across the alternatives. The absence of the tradeoff matrix and tables regarding Guiding Principles and risk and uncertainty has implications that extend far beyond the omissions themselves. In particular, the gaps in the DEIS resulting from these omissions reveal that the agencies fail to provide an accurate, complete and objective analysis of the alternatives when they say (p. 7-4), 59 60 Moreover, the DEIS does not present and apply the general Federal guidance for these types of analysis, especially Executive Order 12866. 1993. Regulatory planning and review; Office of Management and Budget. 2003. Circular A-4: regulatory analysis; EPA. 2002. A framework for the economic assessment of ecological benefits; and EPA. 2010 (updated 2014). Guidelines for preparing economic analyses. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 43 [T]he dam breaching measures in MO3 were carried forward in the analysis to align with the District Court's Opinion and Order, and in response to comments received during public scoping that requested this alternative be evaluated. The omissions show that the agencies, in fact, did not carry forward the socioeconomic implications of dam breaching measures in the analysis, because there is no socioeconomic analysis at all. Thus, from reading the DEIS, the District Court and the public will learn that it fails to identify, describe, and analyze: o Potential economic benefits to the American public as a whole and to specific groups from the higher likelihood, with MO3 relative to other alternatives, of future increases in salmon and steelhead populations. o Potential economic benefits to the American public as a whole and to specific groups from the opportunities, with MO3 relative to other alternatives, for natural river boating and related recreational activities. o Potential economic benefits to the American public as a whole and to specific groups from the improvements in ecosystem health that would result from MO3 relative to other alternatives. o Potential economic benefits to the American public as a whole and to specific groups from reductions MO3, relative to other alternatives, would yield in the risks that the existing infrastructure, programs, and operations create for the survival and recovery of at-risk species. These benefits include potential economic costs savings to American taxpayers, the American public, and specific groups insofar as MO3 reduces the likelihood that the agencies and other parties will have to enact emergency measures in response to plummeting populations of at-risk species, occasioned by climate change and others factors interacting with the CRSO. They also include reduced likelihood that Americans and specific groups will experience reductions in, or complete losses of, the passive-use benefits they derive from fish, healthy ecosystems, etc. o Potential economic costs savings to American taxpayers from reductions MO3 would yield in the risks associated with using the existing infrastructure, programs, and operations to support navigation. Persistent downward trends in navigation demand indicate that vessel traffic will continue to decline and taxpayers subsidies per vessel will increase. If subsidies rise to levels that taxpayers find intolerable, the locks, levees, and related infrastructure will become stranded. o Potential economic costs savings to taxpayers from reductions MO3 would yield in the risks associated with using the existing infrastructure, programs, and operations to generate hydropower. Persistent downward trends in the prices of electricity from solar/wind/energy-storage technologies suggest that consumers increasingly will obtain electricity from them rather than from the Lower Snake River dams. This trend may render continued operation of the dams infeasible, so they become stranded assets. o The likelihood that MO3 will yield larger net public benefits than the other alternatives, including the agencies Preferred Alternative.	The co-leads have conducted an open and transparent NEPA process involving the public and cooperating agencies extensively. As required by NEPA, the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapters 3, 4, 5, 6 and 7; summarized by resource and alternative in Table 3-1, and once again presented for comparison in Tables 7-1 and 7-55. The co-leads, including Reclamation, are not required to conduct an PR&G analysis. The PR&G is intended to provide objectives and guidance to Reclamation for new water resource investments, which include both structural and nonstructural approaches to water supply problems, investments in restoration, as well as other water-related investments. If an agency is seeking authorization and appropriations from Congress to fund a federal investment, it would be appropriate to analyze the alternatives under the PR&G framework. One of the goals of a PR&G analysis is to determine the economically justified alternative by conducting an economic cost benefit analysis, referred to as National Economic Development (NED) effects in the superseded P&Gs. In the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. CEQ NEPA regulations (40 CFR 1502.23) address the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. Further there is no policy or law that requires the use of the PR&G framework. The co-leads, including Reclamation, are not required to conduct and PR&G analysis. Socioeconomic effects of MO3 were fully analyzed and the information presented in Chapters 3, 4, 5, 6, and 7.
3999	66	ttrue@earthjustice.org	Earthjustice	12. Reclamation failed to present full documentation for the selection of the Preferred Alternative. The DEIS does not provide a benefit-cost analysis that transparently compares the net public benefits expected with the implementation of each alternative, nor does it discuss the extent to which the Preferred Alternative maximizes net public benefits. Instead, the DEIS provides an incomplete and misleading comparison of the alternatives benefits and costs. Support for this conclusion comes from Table 3-1. Summary of Expected Effects by Multiple Objective Alternative. The bottom row of the table shows, Total Annual- Equivalent Costs for the Alternatives (2019 $). The data in this row show that the High estimate of the costs for MO3 Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 44 is $1,002 million. This amount is less than the costs shown for the other alternatives. Thus, if the alternatives have only costs, but no benefits, then MO3s lowest costs are functionally equivalent to an indication that it has the highest benefits among the alternatives. In fact, the alternatives also will yield benefits. To some extent the cost estimates already encompass these benefits, for example, by showing (at least according to the agencies analysis) an increase in electricity rates as a cost for one alternative relative to no costs shown for an alternative with no rate increase. MO3 is different, however. Many, or most, of its socioeconomic benefits will result from its diverse, positive ecosystem impacts. Table 3-1 provides no information about these benefits and, hence, they exist entirely outside the tables data. This	As the commenter describes, MO3 is the least costly alternative, ranging from $53 to 158 million per year less costly than the No Action Alternative. The costs to implement the alternatives and operate the system are not an indication of the benefits that the system provides. The beneficial and adverse effects of the alternatives, including the No Action Alternative, are described in various sections in the EIS, including 3.5 (fish), 3.7 (power and transmission), 3.8 (air quality and greenhouse gases), 3.10 (navigation), 3.11 (recreation), 3.12 (water supply), 3.15 (fisheries and passive use), and others. The effects of MO3 on electricity rates are described in Section 3.7 and are not included in the cost estimates described in Section 3.19 and Appendix Q. Table 3-1 provides a summary of all of the effects on all resources, including beneficial and adverse effects. For example, beneficial effects under MO3 in Region C are described for anadromous fish, recreation, fisheries, and Tribal perspectives. Although an ecosystem services approach was not directly followed, ecosystem services were addressed in the appropriate resource section (for example, recreation, water quality, water supply, fisheries, etc.). Finally, a note was added to Table 3-1 to explain that the discussion of costs represents only direct expenditures. It does not represent costs to Bonneville in the form of lost revenues from reduced hydropower generation (discussed in Sections 3.7). It also does not include potential mitigation actions that were identified in Chapter 5 that could be implemented by other entities besides the co-lead agencies.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				disparity in how the table treats MO3s benefits (it doesnt) and the benefits of the other alternatives (it buries them in the cross-alternative cost data) suggests that, if the agencies had included in Table 3-1 estimates of the ecosystem-related benefits of the alternatives, the table would show that MO3 promises the greatest, overall net public benefits.	
3999	67	ttrue@earthjustice.org	Earthjustice	Reclamation and the other co-lead agencies also fail to satisfy transparency requirements when they base their selection of the Preferred Alternative on an analytical framework that uses the No Action Alternative as the baseline for describing and measuring the impacts of the other alternatives. The DEIS attempts to define the No Action Alternative as the baseline, but fails to demonstrate that it adequately and appropriately serves as a credible basis for defining and measuring the Federal investment. In effect, using the No Action Alternative as the baseline for assessing the impacts of the other alternatives fails to account for the full Federal investment embodied in this alternative. For example, it fails to account for the full opportunity costs of committing wetlands and other resources to support continued operation of the existing infrastructure in place. This approach ignores the opportunity costs of the forgone salmon populations, recreational opportunities, and other goods and services that the public would realize if these resources were, instead released from this commitment.	The co-lead agencies defined the no action alternative consistent with NEPA and implementing regulations. In the case of an ongoing action, such as operation of the CRS, the no action alternative represents no change in current management direction or level of management intensity. The no action alternative thus assumes the existence of the CRS projects and does not attempt to hypothesize the direct and indirect costs of each of Congresss decisions to construct CRS projects. The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. The EIS does not employ a cost-benefit framework for decision-making. This is because, consistent with NEPA analysis frameworks (see 40 C.F.R. 1502.23), the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. Consequently, a focus solely on the monetized economic costs and benefits would exclude important tradeoffs associated with the alternatives communicated in the EIS, including effects on fish. Furthermore, while a cost-benefit framework generally results in a ratio of overall benefits to costs, the EIS evaluates the performance of the CRSO alternatives with respect to multiple stated objectives, for example related to improving fish passage and survival, reliable power generation, and minimizing greenhouse gas emissions.
3999	68	ttrue@earthjustice.org	Earthjustice	The agencies use of the No Action Alternative as their baseline also fails applicable standards insofar as they fail to incorporate identifiable risks and uncertainties into their quantification of the No Action Alternative. For example, they do not attempt to quantify the ecological risks that would accompany continuation of current operations for the CRSO. They fail to do so, even as, in Chapter 4, Climate, they describe multiple indicators of these risks and uncertainties (pp. 4- 33, ff., and section 4.2.9.1): o For salmon and steelhead (Oncorhynchus mykiss) in the Columbia basin, climate change may affect the timing of spawning, emergence and migration, cause changes in growth and development, increase predation rates, and affect the availability of critical habitat. In turn, these physiological changes could affect species productivity and abundance (Link, Griffis, and Busch 2015). While habitat conditions may improve for some life stages in certain locations that are currently colder than optimum (Zhang et al. 2019), overall effects on populations due to climate changes that have already occurred in recent decades have been negative (Crozier and Hutchings 2014). Many populations that are sensitive to non-climate threats are also most vulnerable to climate change (Crozier et al. 2008; Crozier 2013). Overall, a warming climate could cause moderate to o Increased variability in flows and reservoir levels could increase stranding/dewatering of larval Pacific lamprey (Entosphenus tridentatus). Pacific eulachon (Thaleichthys pacificus) could experience a mismatch in adult spawning triggers and larval dispersal if winter spawning triggers remain similar but spring freshets peak sooner. Lower summer flows could decrease foraging habitat for green sturgeon (Acipenser medirostris) in the estuary and lower Columbia River. There are several potential outcomes from climate change that could lead to consequences for anadromous fish during the periods of their lifecycle where they reside in the inland water bodies of the Columbia River and its tributariessevere declines in salmon and steelhead populations (Crozier 2015). Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 45 o Projected changes in stream and river temperatures (as described in Section 4.2.3) may cause direct mortality due to heat stress and greater disease susceptibility if the range of physiological tolerance is exceeded (Benda et al. 2015). For example, in the Columbia Basin, Snake River sockeye salmon (Oncorhynchus nerka) are at high risk from heat waves during their mid-summer adult migration (Keefer, Peery, and Caudill 2008; National Marine Fisheries Service 2016). Historical water temperatures have already approached lethal limits for adult steelhead in the upper Snake and middle Columbia Rivers (Wade et. al 2013). Thus, even minor increases in thermal exposure put some of these populations above lethal limits. Increases in water temperatures could result in increased use of cold water refuges by adult salmon and steelhead (EPA, 2019). o [S]almon are becoming smaller and sometimes younger when they return to freshwater, potentially as a result of decreasing pH and increasing temperature (Bisson et al. 2018). o Where high temperature exposure is already an issue, increasing temperatures inside fishways of dams could worsen thermal exposure for migrating adult sockeye, Chinook salmon, and steelhead (Keefer and Caudill 2015). Temperature gradients up to 4 degrees Celsius within fish ladders at dams in the Columbia River appear to block migration by causing adult fish to reverse movement in ladders and fall back downstream (Caudill et al. 2013). Already a serious concern, temperature-related fallback may increase if river temperatures continue to rise (Crozier 2013). o Climate change is also projected to have consequences for the habitat of anadromous fish during the period of their lifecycle where they reside in the Pacific Ocean and Columbia River estuary. Several trends are expected: Reduction in thermal habitat for salmon Increasing ocean acidification Changing estuarine and plume environments o As described in Section 4.2.4, the effects of climate change are expected to have an adverse effect overall on anadromous fish populations, which could lead to moderate to severe declines in salmon and steelhead populations. Available information also suggests that species such as Pacific lamprey, Pacific eulachon, and green sturgeon may also experience adverse impacts from the effects of climate change. Changes in air temperature, precipitation, stream flows, and water temperatures may also have adverse implications for resident fish, including changes in their distribution and abundance (see Section 4.2.3.6). Decreased abundance of anadromous and resident species of importance in commercial and ceremonial and subsistence fisheries could result in a decreased opportunity for harvest, and a decrease in the economic, social, and cultural values associated with fishing. Additionally, changes in the distribution of species associated with the effects of climate change could mean a loss of access to certain species, or increased costs associated with harvesting those species, which could adversely affect those fisheries. The agencies also fail to describe the financial and economic risks in the No Action Alternative associated with projected outputs from the CRSO that support the agencies industrial clients. For example, their depiction of this alternative fails to fully account for trends showing decreasing demand for navigation and increasing competition for hydropower from solar/wind/energy-storage technologies.	The co-lead agencies appropriately analyzed the effects of the No Action Alternative in Chapter 3, 4, 6, and 7. CRS operations, maintenance and configuration is an "on-going action" under NEPA, and thus, the co-lead agencies appropriately determined that the date of the Notice of Intent to Prepare the EIS was the start date of the No Action Alternative. Regarding climate effects to affected resources, please see Chapters 4 and 7. The technical and policy elements of this Draft EIS are in full compliance with binding USACE policy and guidance for qualitative assessment of climate change and its plausible effects. The primary controlling policy and guidance are the USACE Climate Adaptation Policy Statement, signed by the Assistant Secretary of the Army for Civil Works in 2011, updated and signed again in 2013, and remains in force now; and USACE Engineering and Construction Bulletin 2018-14, "Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Projects." The numerical-model simulated outputs were evaluated by multiple technical means (see record of the full USACE Agency Technical Review), and were tested using the set of analytical measures created by the USACE Climate Preparedness and Resilience program to ensure that sound science and engineering was applied in compliance with USACE climate change policy and guidance. Those analytical tests are described in ECB 2018-14 (listed just above) and in USACE Engineer Technical Letter 1100-2-3, "Guidance for Detection of Nonstationarities in Annual Maximum Discharges." The assessment of the effects of climate change is qualitative only in the sense that the biological and other impacts models did not directly ingest the physical hydroclimatology outputs modeled for the assessment. Those hydroclimatology outputs are fully quantitative and so can be the basis for refined estimates of effects should those be required following this Draft EIS. The decline of salmon populations is complex and recovery of those species will take collaboration between various agencies including NOAA and the Tribes. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, have not been fully applied and validated for use with climate affected regulated flow projections of large reservoir systems. These data are critical for analyzing potential effects to fish quantitatively. The same is true for projecting changes to TDG. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitatively assess potential effects to resources (described in Chapter 4). These analyses are documented in Section 4.2.3 for the MO Alternatives and Section 7.8.4 for the Preferred Alternative. Overall, the Preferred Alternative is expected to result in benefits to anadromous salmon and steelhead. The analysis in Section 7.8.4 recognizes that some of the benefits to fish from the Preferred Alternative could be offset by the effects of climate change. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges.
3999	69	ttrue@earthjustice.org	Earthjustice	In sum, the No Action Alternative fails to provide an appropriate baseline, consistent with widely accepted analytical principles, for measuring the impacts of the other alternatives. In effect, the No Action Alternative is a snapshot of today, when the baseline for analyzing the other alternatives must offer an interactive forecasting model of the future. Using the No Action Alternative as the baseline hides the Federal investment embedded in it that would be transferred to and prop up the other alternatives. Using it as the baseline similarly overlooks the risks and uncertainties embedded in it and that would be transferred to the other alternatives. Reclamation and the other co-lead agencies must make explicit these embedded socioeconomic costs before they can satisfy requirements to take a hard look at the alternatives and to identify the alternative that promises the greatest net public benefits. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 46	The co-lead agencies defined the No Action Alternative consistent with NEPA and implementing regulations. In the case of an ongoing action, such as operation of the CRS, the no action alternative represents no change in current management direction or level of management intensity. The no action alternative thus assumes the existence of the CRS projects and does not attempt to hypothesize the direct and indirect costs of each of Congress's decisions to construct CRS projects. Under NEPA, the co-lead agencies are required to analyze a range of alternatives, including the No Action Alternative, to meet the purpose and need of the Project. The EIS analyzing the effects of the No Action Alternative on resources, environmental and socioeconomic, at present and into the future. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapters 3, 4, 5, 6 and 7; summarized by resource and alternative in Table 3-1, and once again presented for comparison in Tables 7-1 and 7-55.
3999	70	ttrue@earthjustice.org	Earthjustice	Their use of the No Action Alternative is not the only place where the agencies made decisions that fail to fully disclose or describe impacts. They repeatedly assert that theyve conducted economic analysis, with no explanation or evidence showing that they did so, in fact. For example, they explain their development of the Preferred Alternative with this statement (p. 7- 21): Following the evaluation of the No Action and MO alternatives, the co-lead agencies selected a combination of measures for the Preferred Alternative based on how well the measures met the Purpose and Need and study objectives, with consideration of environmental, economic, and social effects. [bold highlight added] What does consideration of environmental, economic, and social effects mean? What information, exactly, did the agencies consider? How did they consider this information, i.e., what analytical framework did they apply to the information and what did the analysis show? What criteria were used to select the combination of measures? In the absence of data, analysis, and criteria, what steps did the agencies take to ensure that the selection does not simply represent the biases and preferences of individuals who lack sufficient information to make well-informed decision that will yield the maximum net public benefits? Reclamation and the other co-lead agencies never answer these questions. Their failure to do so indicates that their selection of the Preferred Alternative was arbitrary and not the product of a rational decision in light of all of the available and relevant evidence.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the purpose and need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes the dam breaching measure. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The Co-Lead Agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. The development process is included in Chapter 2 for the No Action and MOs, and Chapter 7 for the Preferred Alternative. The co-lead agencies provided a robust analysis of socioeconomic effects in the EIS. As required by NEPA, the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapters 3, 4, 5, 6 and 7; summarized by resource and alternative in Table 3-1, and once again presented for comparison in Tables 7-1 and 7-55.
3999	71	ttrue@earthjustice.org	Earthjustice	In Section 7.7 EFFECTS OF THE PREFERRED ALTERNATIVE, the agencies state, The environmental, economic, and social effects of the Preferred Alternative were evaluated following its initial development. The effects of the Preferred Alternative have been evaluated both quantitatively and qualitatively, depending on the resource. The following same descriptors are used in this chapter to describe the level of effects: o No Effect: The action would result in no effect as compared to the No Action Alternative. o Negligible Effect: The effect would not change the resource character in a perceptible way. Negligible is defined as of such little consequence as to not require additional consideration or mitigation. o Minor Effect: The effect to the resource would be perceptible; however, it may result in a small overall change in resource character. o Moderate Effect: The effect to the resource would be perceptible and may result in an overall change in resource character. o Major Effect: The effect to the resource would likely result in a large overall change in resource character. How, exactly, did the agencies evaluate the socioeconomic effects of the Preferred Alternative? Did they rely solely on the socioeconomic information included in the DESIS? If so, does this mean they ignored passive-use values? Cultural values? Recreational values? Risks to ecosystems?61 Risks that CRSO will require increasing levels of subsidies or the stranding of infrastructure? If the agencies included this	The Federal agencies factored in this information in their evaluation of the alternatives. The intensity, or potential level of effect, on any resource analyzed across the suite of alternatives is characterized on in Section 3.1 (page 3-3 of the Draft EIS). As discussed in Section 7.7, the Preferred Alternative was evaluated using the same scale of effects that was applied in Chapter 3, 4, 5 and 6. The changes are measured in relation to the No Action Alternative. Similar to the other alternatives, the EIS evaluated benefits and adverse effects of the Preferred Alternative across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the various resource areas Chapter 3 and 7 of the EIS to inform decision-making. The effects of the Preferred Alternative on Passive Use is discussed in Section 7.7.17 (Fisheries and Passive Use), cultural in Sections 7.7.18 (Cultural Resources) and Section 7.7.19 (Indian Trust Assets, Tribal Perspectives, and Tribal Interests), Recreation in Section 7.7.13 (Recreation), and Costs (Section 7.7.2.1). In addition, Section 7.7.21.2 (Summary of Regional Economic Effects) has been added to the Final EIS to further summarize the economic effects associated with the Preferred Alternative. Although an ecosystem services approach was not directly followed, ecosystem services were addressed in the appropriate resource section (for example, recreation, water quality, water supply, fisheries, etc.) in Chapter 7.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				information in their evaluation, where is the information? Why did the agencies not share it with the public? Reclamation and the other colead agencies never answer these questions. Nor did they provide a precise definition of each of the descriptors (No Effect, Negligible Effect, etc.)? They dont explain what information and criteria they used to make these 61 The agencies several times acknowledge that implementation of the Preferred Alternative would interact with expected changes in climate to intensify adverse impacts on ecosystems. For example, in Section 7.8.6 Vegetation, Wildlife, Wetlands, and Floodplain, they state: climate change could exacerbate the effects from the Preferred Alternative on vegetation, wetlands, wildlife, and floodplains. The agencies do not consider the potential interactions and adverse impacts if changes in climate prove to be worse than expected: see, for example, DeFries, et al. 2019. The missing economic risks in assessments of climate change impacts; World Economic Forum. 2019. These are the biggest risks facing our world in 2019; and Ripple, W.J., et al. 2019. World scientists warning of a climate emergency. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 47 definitions or how they applied them? In particular, they provide no information about the socioeconomic elements, if any, included in these criteriafor example, does a change in resource character include a change in its passive-use value? Its recreational value? Ecosystem risk? If so, what socioeconomic information did the agencies use and where did it come from (the DEIS does not contain this information)? Bottom line: insofar as it presents no socioeconomic analysis and supporting data, the DEIS does not demonstratetransparently, comprehensively, and in detailthat Reclamation and the other co-lead agencies satisfied the requirement to take a hard look at socioeconomic changes before they decided the degree to which each element of the Preferred Alternative represents a change in resource character. The absence of a hard look at the socioeconomic effects means Reclamation and the other colead agencies have no fact-based rationale for expecting that their selection and evaluation of the Preferred Alternative will satisfy NEPA, WRDA and the PR&G.	The agencies have evaluated climate change using high quality, current information. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. The rationale for why an impact is considered to fall under one of the preceding intensity descriptors is included in each resource section. Statements of significance are supported by text describing the context and intensity of the impact. As is common in NEPA analyses (see 40 CFR 1502.23), the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Sections 3.5 and 7.7.4. That the effects of the alternatives on fish and recreation are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The co-lead agencies took a hard look at each of the alternatives, including the Preferred Alternative. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Quantitative evaluations were conducted to determine the effects of each of the alternatives when appropriate. In instances where quantitative evaluations were not appropriate or possible, qualitative discussions are included to describe the effects of each alternative. The socioeconomic analysis for the EIS was carefully performed and considered the most relevant information for the analysis. The approach, analysis, and results were thoroughly reviewed by external reviewers, resource managers in the region, and the cooperating agencies. The evaluations are clear, transparent, and repeatable based on high quality information.
3999	72	ttrue@earthjustice.org	Earthjustice	3. Reclamation failed to present an unbiased description of the socioeconomic impacts on different groups. The agencies compound the defects stemming from their use of a faulty No Action Alternative as the baseline with defects in their analysis of the other alternatives. For example, they provide detailed information (p. 7-12) about what they purport to be negative socioeconomic effects of MO3 on farmers. The description includes these details about the potential public costs from implementing MO3: MO3 would also increase transportation-related emissions for wheat that is currently transported along the lower Snake River by up to 53 percent (0.056 MMT of CO2). [T]he cost to transport goods to market would increase (the cost to transport wheat to market is estimated to increase by $0.07-$0.24/bushel. The certainty with which Reclamation and the other co-lead agencies predict these costs lacks evidentiary support and may bias readers and decision-makers against MO3. The agencies do not detail the analytical data, assumptions, and modeling they used to reach these conclusions, nor do they describe the types and levels of uncertainty embedded in these numbers. The agencies seem to be saying that these costs increases will, with absolute certainty, materialize and persist forever following implementation of MO3. Such certainty, absent supporting evidence, deviates from the requirements of widely accepted professional standards applicable to this type of forecast. The problem is compounded because the agencies do not acknowledge and estimate with commensurate certainty the benefits from MO3. Indeed, they overlook these benefits. For example, they dont provide detailed information about the recreational, commercial, or passive-use value of increased or restored fisheries. They dont provide data regarding potential recreationists spending for floating/boating on the free-flowing river, or the additional benefits (called consumers surplus) they would derive from such experiences. The vacuum may cause the public and decision-makers to conclude that the benefits dont exist.	Page 7-12 of the Draft EIS summarizes the impacts to the navigation industry. These impacts, including the analytical data, assumptions, and modeling used to reach these conclusions are described in more detail in Section 3.10. The paragraphs that follow the cited text acknowledge that impacts to the navigation industry would likely decrease over time as the industry shifts to reliance on rail and truck, and that long-term benefits to fish, wildlife, vegetation, floodplains, and wetlands are also anticipated under Multiple Objective alternative 3. The section also identifies potential beneficial effects due to improved fish conditions for recreational, tribal, and commercial fishing activities, and particularly river-based recreational activities. In terms of acknowledging uncertainties in navigation analysis, some additional discussion of the uncertainties has been added into the Final EIS in Section 3.10, and a section summarizing these uncertainties has been added to the Navigation Appendix L.
3999	73	ttrue@earthjustice.org	Earthjustice	The agencies also take a one-sided approach to their assessment of the potential negative effects MO3 would have on users of different types of boating. They openly criticize MO3 because breaching the dams would mean river cruise lines no longer would reach Clarkston, Lewiston, and Asotin, and these communities would lose their river port community identity. Nowhere, however, do the agencies express an analogous concern because the CRSOs past negative effects on fish and the ecosystems have caused Tribal communities to lose their cultural identities. Nowhere do they express an analogous concern because, with the loss of a Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 48 free-flowing river, the Lower Snake River dams caused the community of boaters who used the unimpounded river to lose their identity. In their description of MO4 (p. 7-15), the agencies state: Overall, there would also be major adverse economic effects under MO4. For irrigation on the lower Columbia, the reservoirs levels may be lowered to the point where pumping could no longer be possible. Additionally, in low water years, major adverse effects to water-based recreational access at Lake Pend Oreille could occur. Who determined that these would be major adverse economic effects? What data did they use? What analysis did they conduct? What criteria did they apply to determine that these effects are major? Why did they not make symmetrical statements about any major beneficial economic effects that would materialize? The agencies provide no answers to these questions. Consequently, the DEIS is deeply flawed and incomplete.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. The EIS does not employ a cost-benefit framework for decision-making. This is because, consistent with NEPA analysis framework (40 C.F.R. 1502.23), the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The impacts to anadromous fish in other locations would have negligible to minor changes from the No Action Alternative. Sections 3.11.2 (Recreation Affected Environment) and 3.11.3 (Environmental Consequences) describes recreational fishing in the Snake River. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The EIS describes that the visitation in the lower Snake River, including rafting, kayaking, and recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The social welfare values associated with this visitation were not estimated because of the uncertainty (and large range) in visitation and consumer surplus values among users. It is true that rafting would likely have a much higher consumer surplus value per day compared to other types of activities. Again, there is uncertainty around recreational and commercial fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. However, the EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, the specific quantitative and monetized impacts associated with changes in commercial fisheries under the alternatives was limited. This analysis evaluates potential impacts on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
3999	74	ttrue@earthjustice.org	Earthjustice	In their description of the Preferred Alternatives impact on recreation (Section 7.7.13), the agencies make these statements: In a low-water year, visitation [of reservoir boat ramps] would decrease by less than 1 percent relative to the No Action Alternative. Changes in social welfare value associated with the visitation change in a typical year would be about $3,000. The agencies offer no explanation why they were able to obtain and report data for changes in social welfare associated with a specific decline in reservoir boating but were unable to obtain and report analogous data for changes in social welfare associated with increases in boating on a free-flowing river in MO3 (or losses of social welfare for boaters unable to enjoy a free-flowing river under the Preferred Alternative). These discrepancies in analytical detail indicate biases in the agencies preparation of a DEIS that favors their traditional client industries (farming, navigation, hydropower, hatcheries). Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 49	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective alternative 3, which includes a measure to breach the four lower Snake River dams. However, the Preferred Alternative also meets other objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The changes in social welfare are based on recreational access to reservoirs associated with changes in water surface elevations; when water surface elevations fall below and above operating thresholds of the boat-ramps, access and visitation would be affected Under MO3, the EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. A range of visitation is provided, based on the evaluation conducted for the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and EIS. Although there is uncertainty regarding river recreation in the lower Snake River, in the long-term, there is the potential for river-based recreation and fishing in the long-term, once access has been developed. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. However, there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, which limits the analysis of the specific impacts of each alternative on these recreational fishing values. Because of this uncertainty, the impacts to recreational fishing under MO3 were described qualitatively, indicating that MO3 would support the salmon and steelhead fishery in the Snake River Basin, supporting continued and possibly increased angler visitation in the long-term. The social welfare values and regional economic effects associated with visitation for river recreation post dam breach under MO3 were not monetized because of the uncertainty and large range in visitation and consumer surplus values among users.
3999	75	ttrue@earthjustice.org	Earthjustice	IV. The Socioeconomic Elements of the DEIS Show the Corps Fails to Apply the Agencys Planning Guidance (or Any Planning Guidance Whatsoever) The Corps is subject to the standards and obligations of NEPA and the PR&G, the same as Reclamation. It has not, however, published its agency-specific procedure for complying with the PR&G.62 The Corps website shows, however, that the agency believes the socioeconomic elements of the DEIS should comply with guidance expressed in the Planning and Guidelines (P&G). The agencys Planning Guidance Notebook (p. 2-5) states that the Corps is required to address the following matters in the formulation and evaluation of alternative plans:63 o Enhancing national economic development (including benefits to particular regions that are not transfers from other regions). o Protecting and restoring the quality of the total environment. o The well-being of the people of the United States. o The prevention of loss of life. o The preservation of cultural and historical values. These requirements resemble those of the PR&G and, thus, if the Corps prepared the DEIS under the standards and obligations to the P&G, it should have satisfied most, if not all of the standards and requirements described in the previous sections. In other words, its failure to have adopted agency-specific procedures for	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. Changes in ecosystem functions and services were addressed in the appropriate section of the Final EIS (for example, in water quality, water supply, air quality, recreation, etc.). As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. For example, although the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. Likewise, the EIS recognized and describes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. Thus the EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. As described in Chapter 7 of the Final EIS, the Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as Mutiple Objective alternative 3 (MO3), which includes the measure to breach the four lower Snake River dams. The Preferred Alternative also meets other objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				complying with the PR&G and, instead, comply with the P&G does not justify its participation in and contributions to the failures described in the preceding sections. Other evidence suggests the Corps participated in and contributed to the preparation of the socioeconomic elements of the DEIS subject to no standards and obligations whatsoever. The preceding sections demonstrate that the DEIS does not satisfy standards and obligations of NEPA and the PR&G. If it had participated in and contributed to the preparation of the DEIS subject to the P&G, it would have produced a National Economic Development NED account describing the direct, monetized impacts of each alternative on the national economic wellbeing. The DEIS, however, does not contain a NED account.64 Thus, it appears the Corps failed to apply the standards and obligations of NEPA, the PR&G, the P&G and the Corps own Planning Guidance Notebook. 62 H.R. 1865, Further Consolidated Appropriations Act, 2020, notes that the Corps has yet to develop implementation rules and guidance for the PR&G, and requires the Corps to brief the House and Senate on its plans to do so. The failure to develop agency-specific rules and guidance does not, however, exempt the Corps from its obligations under the PR&G. 63 U.S. Army Corps of Engineers. 2020. Planning Guidance Notebook. This document states: The Planning Guidance Notebook provides the overall direction by which the Corps of Engineers civil works projects are formulated, evaluated, and selected for overall implementation. 64 The DEIS does, however, refer to NED-related guidance from a component of the Planning Guidance Notebook, p. 7-169): The Corps guidance describes the following: Primary benefit measure for hydropower: Market value of output, or alternative cost of providing equivalent output when market price does not reflect marginal costs. (Source: U.S. Army Corps of Engineers Institute for Water Resources. June 2009. National Economic Development Procedures Manual.) This statement indicates that, while preparing the DEIS, the Corps believed it was subject to the guidance from the Planning Guidance Notebook. The Corps, however, offers no explanation for why it cited the guidance when convenient, but did not endeavor to satisfy the full set of standards and obligations defined in the Planning Guidance Notebook. Natural Resource Economics, Inc. Comments on Socioeconomic Elements of CRSO DEIS 50	Regarding the P&G or PR&G requirements, if an agency is seeking authorization and appropriations from Congress to fund a Federal investment, it would be appropriate to analyze the alternatives under a P&G or PR&G framework. Under the NEPA context, the goal is not to determine the economically justified alternative for OMB approval. Section 1502.23 of the NEPA regulations (40 CFR 1502.23) addresses the role of cost benefit analysis within the context of NEPA compliance. The first half of Section 1502.23 discusses the incorporation of existing benefit-cost analyses into the NEPA evaluation process. The second half of Section 1502.23 states that (f)or purposes of complying with the Act, the weighing of the merits and drawbacks of the various alternatives need not be displayed in a monetary cost-benefit analysis and should not be when there are important qualitative considerations. Further there is no policy or law that requires the use of the PR&Gs. Furthermore subsequent studies, such as NEPA and feasibility studies, would likely be conducted prior to implementation of an alternative such as MO3.
3999	76	ttrue@earthjustice.org	Earthjustice	V. Illustrative List of Relevant Socioeconomic Information the Co-Lead Agencies Failed to Incorporate into the DEIS Table 6 provides a partial list of some of the relevant information that was readily available to, but not used by, the co-lead agencies. Failure to incorporate this information in the DEIS leaves large gaps in the DEISs identification, description, and analysis of the socioeconomic impacts of each alternative and the comparison of these impacts across the alternatives. These gaps, in turn, constitute a fatal flaw in the agencies attempts to satisfy NEPAs requirement, that they must take a hard look at all of each alternatives impacts. Table 6. Economic profile system Maximize public benefits and promote sustainable economic development, accounting for economic impacts of national parks and related public lands	The EIS socioeconomics analysis reviewed a wide range of published sources, some of which were ultimately cited to support the approach and analysis, while others were not. While a few of the suggested references could have been cited in the EIS, they would not fundamentally change the approach or analysis, or lead to different determinations. Many of the suggested references are general literature or guidance documents. The socioeconomic analysis for the EIS was carefully performed and considered the most relevant information in the timeline provided for the work for the subjects of the analysis. The approach, analysis, and results were thoroughly reviewed by external reviewers, resource managers in the region, and the cooperating agencies.

Instead, it illustrates the variables the co-lead agencies should have included in the DEIS, and it provides a starting point for the agencies to correct the deficiencies as they prepare the final EIS. b This list does not identify all the information on each variable that is missing from the DEIS. Instead, it illustrates the information the co-lead agencies should have identified, reviewed, and included in the DEIS, and it provides a starting point for the agencies to correct the deficiencies as they prepare the final EIS.	
4003	1	hickorybiehn@yahoo.com	N/A	If salmonid species are truly the top priority forcing the removal of dams, try killing the sea lions hanging out at the mouth of the Columbia River or at Bonneville Dam. ODFW AND WDFW could both offer a hunting season on the sea lions, creating revenue for each state agency while protecting the fish.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
4007	1	N/A	N/A	Much like the Cle Elum dam in Washington, I suggest that we utilize the fish transporting system by Whooshh Innovations for the salmon. The mechanism is more cost efficient (roughly 1/6 of the cost of traditional fish passages), creates jobs, brings salmon back to native lands without harming them, and allows the dams to stay operational. While this system for transporting salmon may seem unusual, sometimes we need individuals that think outside the box to inspire change.	The four lower Snake River and four lower Columbia River dams have ladders installed that safely and effectively pass millions of adult salmon upstream. Adult upstream passage success through these dams is relatively high, generally around 90% from Bonneville to Lower Granite dam. In addition to passing up to 60,000 salmon per day, some of these dams may pass upwards of 250,000 shad in a single day. Passing this large number of fish over a false weir, sorting them, then passing them through single, wetted tubes, is not practical, or needed, and would require significant research and development, even if deemed feasible. The technology of fish cannons or similar devices has demonstrated some success on smaller scales, and their use will continue to be evaluated for future applications.
4011	1	fkmangan@hotmail.com	N/A	Also, I believe that a concerted effort to replace existing fish ladders with a better design would improve fish migration.	The CRSO EIS evaluated improvements to fish ladders in the Multiple Objective alternatives. Adult upstream passage success through the four lower Snake River and four lower Columbia River dams is relatively high (generally around 90% from Bonneville to Lower Granite dam). While there is some loss associated with dam passage, it is not typically a problem of ladder passage but rather fallback of adults over the spillway or through turbines, and unaccounted harvest and straying. However, the Draft EIS does present several measures to improve existing ladder designs (including improvements for temperature, traps that are part of the ladders, and the Bonneville Dam upper ladders). As described in Section 7.6.2, the Preferred Alternatives includes, for example, the Bonneville Ladder Serpentine Weir Modification measure that is expected to reduce stress and delay for adult salmon, steelhead and bull trout and has the potential to increase adult salmon and steelhead survival by reducing upstream passage time at the dam.
4021	1	paullindholdt@gmail.com	N/A	The federal agencies ignored the importance of salmon and steelhead sportfishing to Idahos river communities, as well as the many outdoor recreation opportunities possible on a restored Lower Snake River.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multiple objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. Under MO3, the EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in Region C that would occur under a dam breach scenario as major and beneficial. The potential for increases in recreational fishing under MO3 in Region C is described in Section 3.11.3.5, which would support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. For MO1, MO2, MO4, and the Preferred Alternative, the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term.
4025	1	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	2-36 lines 1151 through 1164. Closure of the hatcheries funded by BPA will result in a loss of 19 million salmon, steelhead and resident rainbow trout (3-897 24727) being cultivated and released to the Snake River on an annual basis. This Impact has been identified but no mitigation measure has been presented in the EIS.	The Draft EIS acknowledges that with breaching the four lower Snake River dams in MO3, there would no longer be an obligation for Bonneville to fund the U.S. Fish and Wildlife Service (USFWS) for operations of the the Lower Snake River Compensation Plan hatchery facilities, which account for much of the hatchery production in the basin and other Bonneville-funded mitigation activities could be adjusted. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. Over time, increased returns of wild fish would be expected as wild fish replace hatchery fish, and the Snake River resident fishery would improve as the reservoir habitats transition to riverine. The long term effect of MO3 would be beneficial for Snake River salmon and steelhead, so no mitigation for this effect was identified. Additional hatchery production would be in place for limited years to offset the short-term dam breaching and construction effects. Mitigation measures are proposed for both anadromous and resident fish for a transitional period for the breaching of the four lower Snake River dam embankments, as described in Sections 5.4.3.2 and 5.4.3.3. Proposed mitigation includes two years of hatchery production along with trap and haul operations for the anadromous and resident fish during this period. These mitigation measures would reduce adverse effects to resident and anadromous fish in Region C.
4025	2	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	2-37 1161 through 1164. Corps also provides annual funding to implement other components of the LSRCP such as the management units for upland and riparian habitat (woody, riparian initiative), a game bird farm, and other ongoing habitat management at locations across the lower Snake River basin. LSRCP would be continued, consistent with the No Action Alternative, under all of the Multiple Objective Alternatives except for MO3. At what point would the Corps cease funding these environmental measures? What would that mean for the ownership of the property? The city would like to see a map of the management units in question at a scale sufficient to identify areas of concern and provide comments.	There is property owned by the Corps that is managed for wildlife habitat and other recreation as part of the Lower Snake River Compensation Plan. The commitments for woody riparian and game farm programs have beeen completed. If MO3 was selected as the Preferred Alternative, further evaluation and site-specific NEPA would be completed along with a request for congressional authorization and appropriations to complete the implementation of the alternative. Any real-estate transactions of current Federal properties would be included as part of implementation of the MO3 alternative.
4025	3	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-272 6252 through 6254. The release of the currently shoaled sediment, which contains historical pollutants (pesticides, dioxins, other human-sourced pollutants and naturally occurring mercury in volcanic soils and from atmospheric deposition) would impact sediment quality in the lower Snake River. Improving Salmon Passage, February, 2002 pg. 30 indicates that manganese, and un-iodized ammonia are also a concern. Lewiston requests a specific study be conducted of the newly exposed sediment along the waterway. If any constituents of concern are discovered, Lewiston requests that they be mitigated.	If MO3 is identified as the selected alternative in the Record of Decision (ROD), the co-lead agencies would study potential site-specific contamination issues in a National Environmental Policy Act (NEPA) analysis for the implementation of that alternative. However, the co-lead agencies are unaware of any actions on their part that caused a release of hazardous substances into the reservoirs or river that has caused the potential contamination that the commenter identified. The existence of the dam and the fact that sediments are retained by the dam does not create liability for those potential hazardous substances in the sediment. Therefore, even if an evaluation identifies potential contamination in the sediments, without confirmation that the potential contamination was caused by a release of a hazardous substance by the co-lead agencies, the agencies would not have the authority to expend Federal appropriations on a cleanup of contamination that was caused by others. If there are areas where the co-lead agencies are the liable party for the release of hazardous substances into the environment, the co-lead agencies would evaluate and take appropriate actions to address the contamination. This includes areas that the co-lead agencies have already committed to monitoring if MO3 is the selected alternative.
4025	4	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-548 16557 through 16558. Currently, hatchery fish account for 80-90 percent of all juvenile Snake River fish passing CRS projects. COMPASS and CSS models do not account for this potential major reduction in juvenile fish production. This impact, in regards to the entire size and health of the fishery, has not been evaluated. Without a robust analysis, persons may be misled as to the impact of dam breaching on the fishery.	The Draft EIS acknowledges that with breaching of the four lower Snake River dams in MO3, there would no longer be an obligation for Bonneville to fund the U.S. Fish and Wildlife Service (USFWS) for operations of the the Lower Snake River Compensation Plan hatchery facilities, which account for much of the hatchery production in the basin and other Bonneville-funded mitigation activities could be adjusted. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish, as well as the abundance considering the cessation of transportation, is qualitatively discussed in Section 3.5.3.6. The fish models are based upon data collected from past fish runs and there is no data available to inform a quantitative analysis for wild fish in the absence of hatchery fish. The long-term overall effect of MO3 would be beneficial for Snake River salmon and steelhead as well as resident fish. Over time, recreational fishing gains would be expected as wild fish replace hatchery fish, but the timeframe and numbers of fish was speculative and not quantifiable for this analysis.
4025	5	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-559 16895 through 16902. The COMPASS and CSS modeling results indicate that survival rates would increase by as much as 25% and travel times would decrease by as much as 30% relative to the No Action Alternative. However, as reductions in hatchery fish could reduce the numbers of juvenile Snake River Chinook by as much as 85%. This reduction in the number of hatchery fish would likely result in a reduction of these predicted survival rates of wild Chinook because of increased predation rates. The dam breach measures in MO 3 would eliminate the transportation program juvenile Snake River spring/summer-run Chinook. This impact is identified in the EIS but no mitigation measures have been provided.	The Draft EIS acknowledges that with breaching of the four lower Snake River dams in MO3, there would no longer be an obligation for Bonneville to fund the U.S. Fish and Wildlife Service (USFWS) for operations of the Lower Snake River Compensation Plan hatchery facilities, which account for much of the hatchery production in the basin, other Bonneville-funded mitigation activities could be adjusted, and transportation of Snake River salmon and steelhead would no longer occur. The effects to populations as they transition from primarily hatchery production to increased wild production, as well as the abundance considering the cessation of transportation, is discussed qualitatively in Section 3.5.3.6. The fish models are based upon data collected from past fish runs and there is no data available to inform a quantitative analysis for wild fish in the absence of hatchery fish. Over time, increased returns of wild fish would be expected as wild fish replace hatchery fish, and the models predict increased returns despite lack of transportation. The long-term effect of MO3 would be beneficial for Snake River salmon and steelhead so no mitigation for this effect was identified. Additional hatchery production would be in place for limited years to offset the short term dam breaching and construction effects. Mitigation measures are proposed for both anadromous and resident fish for a transitional period for the breaching of the four lower Snake River dam embankments as described in Sections 5.4.3.2 and 5.4.3.3. Proposed mitigation includes two years of hatchery production along with trap and haul operations for the anadromous and resident fish during this period. These measures would reduce adverse effects to resident and anadromous fish in Region C.
4025	6	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-585 17794 through 17796. Short term effects include high sediment and low oxygen concentrations that would likely lead to the loss of most of the fish in this reach during breaching, reduced forage and productivity for 2-7 years following breaching, and potential migration barriers at tributaries that may become perched during reservoir drawdown. Xxx The Agencies should estimate the total size of the fishery (including all types of fish) before and after dam breaching. This impact has been identified but no mitigation measures presented in the EIS. Once the river is stabilized and fishing can resume, the City asks the Agencies to fund a robust marketing campaign to bring the fishermen back to the Snake and Clearwater Rivers.	Currently, there are not good estimates of resident fish populations in the lower Snake River. The best sources of information are localized reports on specific fish populations and angler catch information areas of the basin. The effects to populations as they transition from primarily hatchery production to an increased wild production, as well as the abundance considering the cessation of transportation, is qualitatively discussed in Section 3.5.3.6. The fish models are based upon data collected from past fish runs and there is no data available to inform a quantitative analysis for wild fish in the absence of hatchery fish. Over time, increased returns of wild fish would be expected as wild fish replace hatchery fish, and the models predict increased returns despite lack of transportation. The overall effect of MO3 would be beneficial for Snake River salmon and steelhead so no mitigation was identified. While the co-lead agencies recognize the importance of angling recreation to the region as stated in Section 3.1.3.5, Recreation Environmental Consequences Section for MO3, the co-lead agencies would not have a role in providing recreational facilities or recreational marketing. The National Environmental Policy Act (NEPA) requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The mitigation requested is not within the co-lead agencies' current authorities.
4025	7	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-732 22518 through 225225. It is not clear how raising the allowable reservoir elevation would impact the Lewiston levee system. Please explain so that the city may appropriately comment.	The commenter is correct that under Multiple Objective alternative 2 (MO2), the reservoir elevations at the four lower Snake River dams would differ from the No Action Alternative due to the Full Range Reservoir Operations measure, which calls for operating within the full reservoir operating range throughout the year. Under MO2, Lower Granite reservoir would still continue to have a hinge pool operation similar to the No Action Alternative during high flows, which would have the reservoir operate at lower levels to manage high flows on the levees near Lewiston, Idaho. There is no increase in flood risk under all alternatives examined in the EIS.
4025	8	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-747 22976 through 22978. Approximately 3,000 acres of habitat management units that are currently irrigated under the No Action Alternative would no longer be irrigated, and these lands would transition to upland plant communities. Lewiston endured the loss of riverfront views and other amenities when slackwater arrived. We were compensated by the installation of recreational amenities along the levee including irrigation. The loss of irrigation will leave us in a brown bowl with significantly less natural beauty. The impact on Lewiston regarding visual impacts, recreation and sense of place should be evaluated and mitigated.	The visual resource analysis in the Final EIS summarized in Section 5.4.3.4 describes the visual change that would result from the 3,000 acres of habitat management units that would transition to upland plant communities under Multiple Objective alternative 3 (see also Section 3.13.3.4 in the Draft EIS). Mitigation actions have been identified to replant upland native vegetation in these areas.
4025	9	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-746 22959 through 22963. In general, short-term effects to plant communities would occur within 10 years of dam breaching; long-term effects or changes would occur after a minimum of 60 years. To the extent that the plant communities stabilize river banks, provide recreational benefits, wildlife and fisheries food, cover and shade and will take 60 years to transition and stabilize, substantial mitigation efforts are needed for areas exposed by receding reservoirs. This mitigation should include removal of contaminated soils and 45 years of accumulated trash. 3-749. 23059 through 23061. Long-term gains are based on the assumption that habitats will return to their pre-project distribution. It does not assume that habitat management units or Corps managed lands will be maintained. Identified mitigation is based on the Corps owning and maintaining the land. Page 3-78 23007 indicates the Corps will not own the land in the future. Lewiston notes that pre-project distribution will never be attained adjacent to the levee structures with their large rip rapped water-side.	To offset effects to existing upland, wetland, and aquatic vegetation, reducing the quality, quantity, and distribution of habitats, mitigation proposed would be to replant approximately 13,000 acres of arid, upland native vegetation on newly exposed soils and approximately 1,500 acres of emergent and forested, scrub-shrub wetland habitat adjacent to the new surface elevations of the lower Snake River as described in Section 5.4.3 Mitigation Measures Proposed for MO3. NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested for removal of contaminated sediments, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. If MO3 is identified as the selected alternative in the ROD, the co-lead agencies would study potential site-specific contamination issues in a NEPA analysis for the implementation of that alternative. However, the co-lead agencies are unaware of any actions on their part that caused a release of hazardous substances into the reservoirs or river that has caused the potential contamination that the commenter identified. The existence of the dam and the fact that sediments are retained by the dam does not create liability for those potential hazardous substances in the sediment. Therefore, even if an evaluation identifies potential contamination in the sediments, without confirmation that the potential contamination was caused by a release of a hazardous substance by the co-lead agencies, the agencies would not have the authority to expend Federal appropriations on a cleanup of contamination that was caused by others. If there are areas where the co-lead agencies are the liable party for the release of hazardous substances into the environment, the co-lead agencies would evaluate and take appropriate actions to address the contamination. This includes areas that the co-lead agencies have already committed to monitoring if MO3 is the selected alternative.
4025	10	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-750. 23075 through 23079. Large mammals that are associated with forested wetland habitats, such as mule and white-tailed deer, would be temporarily adversely impacted by a reduction in suitable foraging habitats and protective cover during and immediately following dam breaching as existing wetland habitats transition to upland grassland or shrub-steppe habitats. The agencies are requested to evaluate how the loss of these animals may change hunting opportunities and the economic value of that recreational activity.	The potential for impacts under MO3 to vegetation, wildlife habitat, and associated impacts to hunters as the area transitions from reservoir to riverine are described qualitatively in Section 3.11.3.5. Due to the uncertainty surrounding the effects, these impacts are not quantified.
4025	11	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-762 23468 through 23473. Lewiston requests a map of where vegetation mitigation and invasive species control will occur at sufficient scale so that we can identify any concerns and provide appropriate comments. (Also, Q-6-6 1015 through 1023).	The specific details of the mitigation plan for MO3 have not been developed, but are generally included in Chapter 5. If MO3 was selected and authorized by Congress, an implementation plan and associated National Environmental Policy Act (NEPA) analysis would be prepared that would include site specific information that details the construction, breaching, disposal, and mitigation actions required to implement MO3, as well as identifying all of the associated permitting for this action. The mitigation plan for the Preferred Alternative is described in Chapter 7.
4025	12	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-936 28236 through 28238. The increased cost of electricity could increase the cost of living and doing business in the Pacific Northwest, resulting in regional economic impacts of $740 million in lost outputs (sales) and 4,900 jobs. This impact has been identified but no mitigation measure has been presented in the EIS..	The information provided in the comment regarding the power-related regional economic impacts of breaching the four lower Snake River dams is consistent with the findings of the EIS. Although there would be socioeconomic impacts of increased electrical costs, the loss of benefits provided by the system would not be mitigated.
4025	13	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-1013 30524 through 30527. Overtime, the risk of fugitive dust likely declines as vegetation covers the exposed sediment, reducing the potentially erodible area. Additionally, potential effects may be mitigated by planting of vegetation, restrictions on activities on the sediment such as recreation and the use of vehicles, or by use of wind barriers for recreation areas. Lewiston would like a map prepared at sufficient scale to indicate where newly planted areas would be located so that we may provide appropriate comments. Project impacts to recreational visits should be expanded to include the loss of recreational use while newly exposed sediments are being revegetated. This section of the document seems to conflict with the 1992 OA/EIS. That document, Appendix pages 4-59 stated The 1992 OA/EIS identified three air quality concerns relative to operation of the reservoirs. The first was fugitive dust generated by strong winds blowing across exposed sediments during dry conditions. These conditions can result in high dust loadings and	The air quality analysis in Section 3.8 of the EIS evaluates potential effects from fugitive dust due to exposed sediment by considering wind speed and conditions from various locations in the region. This analysis additionally describes the potential for higher risk of adverse health effects from fugitive dust under MO3, which may acutely affect certain populations, such as people with asthma. Section 5.4.3.4 describes the mitigation plan for planting of exposed sediments following breaching of the four lower Snake River dams under MO3. Mitigation would include replanting approximately 13,000 acres of newly exposed soils and approximately 1,500 acres of emergent and forested, scrub-shrub wetland habitat. As described in this comment, Section 3.8 of the EIS identifies that, over time, there would be a reduction in the risk of fugitive dust due to growth of vegetation. Likewise, increased odor from exposed sediment would be temporary and would be reduced over time following mitigation. The cruise line analysis used the best available data at the time. Given an increase in passengers, it is possible that regional economic effects would also be proportionally higher. However, there is uncertainty in these figures and the resulting regional economic benefit estimates; it is likely that the evaluation has captured the numbers of passengers and regional economic effects within an acceptable range of uncertainty.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				nuisance conditions for nearby residents and recreational users of the reservoirs. The second concern was odors that arise from decaying organic matter in sediments exposed to the air. The 2020 EIS does not address these nuisance conditions already documented by the Corps. The Agencies should note that Asotin County has an occurrence of asthma higher than neighboring counties. (Innovia Foundation. A Region-Wide Community Needs and Opportunity Assessment, January, 2020, Appendix F). 3-1081 32115. Cruise ship passengers are listed as 18,000 in 2017. According to the Port of Clarkstons December 2018 Outlook, cruise ships generated an estimated 25,000 visits to the LC Valley. Please update the economic analysis with this new number.	
4025	14	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-1137 33517 through 33522. Infrastructure investments are transitional costs, and would primarily be borne by private entities including rail lines and grain shippers. Over time, prices should adjust to cover these costs. Some highway costs would be transferred to the trucking industry through fees, though most costs would likely be borne by public entities. State and local resources are not sufficient to maintain existing roads to an acceptable standard. The impact has been identified but no mitigation measure has been presented in the EIS. The 2002 EIS (Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement) identified 5 bridges in the Lewiston area that could be affected by permanent drawdown of the reservoirs: Red Wolf, Snake River Highway Bridge (Route 12), Southway, Lewiston (Camas Prairie) Railroad Bridge and Clearwater Memorial Bridge. (Appendix D, Annex E) These highway and railroad bridges were evaluated to determine the adequacy of the existing foundations and abutment protection to resist post drawdown flood scouring to natural stream levels. Almost all required some degree of protection. Each of these bridges should be evaluated and retrofitted as necessary by the agencies as mitigation of MO 3. The 2002 EIS, Appendix D, Annex H, states There is no doubt that many of the railroad and highway embankments will be damaged as a result of rapid reservoir drawdown. As drawdown occurs, areas of the embankments along the river are anticipated to fail due to steep slopes, saturated soils, and pore pressure increase. The 2002 EIS cites observations from the 1992 drawdown tests that include impacts to the Camas Prairie Railroad embankment, two small slides near Red Wolf Marina on US HWY 12, and disturbance of many survey monuments.	Mitigation was proposed for infrastructure affected by MO3 in Chapter 5. However, costs for roadway maintenance outside of the breaching action would remain the responsibilities of the agency with jurisdiction for the road. The National Environmental Policy Act (NEPA) requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures would not be included in the Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. If MO3 was selected and authorized by Congress, an implementation plan would be prepared that would include site specific information that details the construction, breaching, disposal, and mitigation actions required to implement MO3, as well as identifying all of the associated permitting for this action.
4025	15	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-1141 33658. Update cruise ship passenger figure to 25,000. 3-1147 Table 3-248. Major adverse effects as the jobs and income provided by the four primary commercial navigation ports would be curtailed. Investment in infrastructure may be required, including upgrades to rail infrastructure, added shuttle rail capacity, and increased road maintenance costs. Adverse effects due to reductions in regional economic benefits to port cities where cruise line expenditures would have occurred. Although identified as major and adverse, no mitigation measures are put forward to offset these impacts. Area Ports have been partnering in a multi-year dark fiber project to improve broadband access throughout the region. Without the Ports and their revenues, this project is expected to come to a halt, impacting the regions ability to attract economic development.	The EIS discusses many of the potential concerns that you raise in Section 3.11 Navigation and Transportation, including increased shuttle rail capacity and road maintenance costs, as well as potential adverse effects on cruise ship operations under Multiple Objective alternative 3 (MO3). The cruise line analysis used current, high quality data at the time. Given an increase in passengers, it is possible that regional economic effects would also be proportionally higher. However, there is uncertainty in these figures and the resulting regional economic benefit estimates; it is likely that the evaluation has captured the numbers of passengers and regional economic effects within an acceptable range of uncertainty. The mitigation requested for effects to regional economic benefits is not within the co-lead agencies' current authorities. As described in Chapter 5 Mitigation, specific regulations guide the development of appropriate mitigation measures to address environmental effects. If breaching were selected as the Preferred Alternative, further, more detailed evaluations and National Environmental Policy Act (NEPA) analysis would be needed along with congressional authorization and appropriations to more completely assess the engineering requirements of the project and to potentially further refine and develop mitigation measures. As described in Section 5.1.1., Overview of Mitigation, mitigation measures developed as part of a NEPA process are not intended to indicate the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures described. But, rather it provides a list of potential mitigation needs which could potentially include some infrastructure items, some of which could be implemented by other agencies, officials or the public who would potentially benefit from the mitigation measure.
4025	16	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-1165 289 through 290. Region C encompasses at least 129 recreation points on or near water that are managed by Federal and state agencies and private (for profit) entities. This impact has been identified but no mitigation measure has been presented in the EIS. An appropriate mitigation would be evaluating each of these recreation points to determine how visitors could access the water. The federal agencies could then fund the access projects. 3-1213 1643 through 1645. Although it is uncertain who would own and manage the lands in the lower Snake River, recreational facilities, infrastructure and/or recreational access would need to be developed to facilitate river recreation visitation to the region. This impact has been identified but no mitigation measures presented in the EIS. Please provide a map at sufficient scale so that Lewiston can evaluate which properties might change hands and provide appropriate comments. Lewiston notes that sale of Federal land on the water side of the levee for any use other than open space and recreation could have an adverse impact on the community and its ability to see and access the rivers. Lewiston supports Corps ownership and maintenance of recreational amenities along the Snake and Clearwater rivers on both sides of the levee.	Chapter 5 in the EIS describes the proposed mitigation measures under each of the Multiple Objective alternatives (MOs). Section 5.4.3.6 describes the potential mitigation measures for recreation under MO3. No Federal mitigation is anticipated under MO3 to maintain access to the river. The mitigation requested is not within the co-lead agencies' current authorities. Since the four lower Snake River projects would be deauthorized, it is likely that the co-lead agencies would no longer operate the project lands for recreation. After project lands have been transferred to other agencies or entities, recreational sites and associated facilities could be modified as determined by others.
4025	17	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-1214 1689 through 1691. Lake or flat-water recreational activities, including water skiing, sailing, motor boating (in fiberglass boats), fishing for some warm-water species, and sight seeing in tour boats that cruise between Portland and Lewiston, would no longer be possible if breaching would occur. Loss of local market value of these watercraft should be evaluated and mitigated. The registration fees for these watercraft are used to support waterway improvements at the county level including policing and search and rescue. The Nez Perce County Sheriff has two 23 long boats, too small to effect a complex rescue in high flow, fast water conditions. This community safety impact has not been measured in the EIS so mitigation measures can be confirmed. The Snake River reservoir also supports a Seaplane Base (SPB-78U). It is open to general aviation (private and commercial) and military aircraft that can land on water. During firefighting season this base may be of critical importance to the region. Seaplanes can only land on water, making this base of particular importance when planes need to be moved across-country. This impact has not been evaluated in the EIS nor mitigated.	Impacts to recreational activities, including adverse effects associated with flatwater recreation activities under the MO3 alternative, are described in Section 3.11. The mitigation requested for loss of market value of watercraft is speculative and not within the co-lead agencies' current authorities. While potential effects on seaplane use for firefighting were not described in the Draft EIS, and most firebombers in the region use retardant that is filled by trucks at airports, it is possible that Lower Granite pool in Lewiston/Clarkston may be used for firefighting planes and helicopters capable of picking up water from a large body of water. This use would be made more difficult following breaching of the four lower Snake River dams under MO3 due to reduced water depths and area. A description of this potential effect has been added into Section 3.10.3.5 under Navigation and Transportation.
4025	18	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-1226 Table 3-264. Expand table to reflect loss of hunting visitor days, and associated value to the economy.	The visitation data described in Section 3.11.2.2 was obtained from state and Federal agencies; much of the available data reflected reservoir recreation. According to the types of visitors for the data provided, approximately 1% of visitation in Region C are hunters (Table 3-257 in Draft EIS). Hunters are categorized as land-based recreators. Under MO3, in the short-term, 1.7 million land-based visitors would be affected, including hunters. Additional description of the adverse effects in short-term to visitation, social welfare, and regional economic effects associated with MO3 are described qualitatively in Section 3.11.3.5. Due to the uncertainty surrounding the effects, these impacts are not quantified.
4025	19	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-1245 2541 through 2542. The City of Lewiston and Potlatch Corporation (now Clearwater Paper) have water supply intakes on the Clearwater River above Lower Granite Dam. According to the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and EIS, so does Atlas Sand and Rock, Lewiston Country Club Golf Course (a private entity) and the Clarkston Country Club (Tribal). The agencies should rebuild or relocate these intakes to function in Riverine conditions. (Appendix D, Annex R).	The National Environmental Policy Act (NEPA) requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide mitigation for the effects to private infrastructure such as water supply intakes.
4025	20	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-1286 3896 through 3898. The loss of the wide reservoirs would permanently expose portions of shoreline or reservoir bottom leading to temporary dust effects, erosion susceptibility, and rendering previous shoreline recreation obsolete. This impact has been identified but no mitigation measures presented in the EIS. Another impact not taken into account is the loss of property values associated with water views. These property premiums directly translate into property taxes with which the city funds critical services. This impact has not been measured nor mitigated.	Section 5.4.3 and Table 5-3 in the Draft EIS describe the mitigation measures that are identified to reduce the adverse effects of MO3. As described in this section to offset the adverse effects of the reservoir drawdown on vegetation and water quality, the mitigation proposed would be to replant approximately 13,000 acres of arid, upland native vegetation on newly exposed soils and approximately 1,500 acres of emergent and forested, scrub-shrub wetland habitat adjacent to the new surface elevations of the lower Snake River. This would mitigate dust effects and erosion, reducing effects on recreation and adjacent communities. The long-term effects of breaching the four lower Snake River dams would have both positive and adverse results depending on the context and individual preferences and values. If breaching were to be selected as the Preferred Alternative, further evaluation, studies, and the National Environmental Policy Act (NEPA) would be needed along with congressional authorization and appropriations to assess the requirements of the project and to potentially mitigate for the changes in river conditions. At this time, there is no mitigation proposed for adverse effects to recreation because the co-lead agencies would no longer operate the project lands after the projects are de-authorized. The mitigation requested for loss of property value is not within the co-lead agencies' current authorities.
4025	21	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-1287 3907 through 3908. The loss of earthen embankments and some project infrastructure associated with dam breaching is mentioned several times. Leaving in place the powerhouses, spillways and other features will constitute an attractive nuisance and a hazard to river users. Rescuing trespassers would fall to local agencies. This impact is not discussed nor mitigated in the EIS. All power lines to the dams that are no longer needed should be removed.	The decision to leave some of the dam infrastructure in place was due to the removal of large dam infrastructure being very costly. Under MO3, structural protections would be built around the remaining dam and power infrastructure, which is described in Annex A of Appendix Q. In addition, security detail would occur at the projects to monitor the sites as they would remain Federal property, which is described in Section 5.2.4 of Appendix Q. These costs are included as part of the MO3 cost analysis (structural measures and operations and maintenance (O&M)).
4025	22	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-1462 9416 through 9418. Under MO3, pumps and wells that supply municipal and industrial uses in the Lewiston area would no longer be operational once the dams were breached. The narrative goes on to describe the loss of 55 jobs and 9.8 million in labor and sales as minor. As the largest community in region C and on behalf of Clearwater Paper, the largest employer in the region, we do not agree these impacts are minor. We specifically request the agencies fund retrofits of our systems to operate in a riverine condition. On the subject of Clearwater Paper, they employ 1,400 persons who in turn support 2,246 jobs, and have an economic value to the community of $152,699,602. (EMSI Q2 2019 Data Set). The cumulative effect of increasing transportation costs, modifying intakes, modifying discharges and the cost and lack of certainty in the ability to obtain a new discharge permit may be a fatal blow to the company. This impact has not been measured in the EIS nor mitigated. Improving Salmon Passage, Final Lower Snake River Juvenile Salmon Mitigation Feasibility Report/EIS February, 2002, Summary Page 33 estimated the modification costs for pumps owned by industrial and municipal parties as $11,514,000 to $55,214,000. The 2020 EIS does not estimate the cost of upgrading these facilities.	The National Environmental Policy Act (NEPA) requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide mitigation for the effects to private infrastructure such as irrigation pumps, wells, or private docks. This EIS discusses engineering solutions (pipeline extensions for example) in Section 3.12.3 Environmental Consequences; specifically in Region C under MO3, see page 3-1267, line 3244, in the Draft EIS and Appendix N. The report which this EIS draws upon, as discussed, concluded that modifying the existing pump system was cost prohibitive. In Region C, for MO3 the analysis accordingly assumes that pumps are unable to deliver water to estimated at 48,000 acres.
4025	23	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-1463 9459 through 9466. Loss of visitors are described as costing the region $103 million, a decrease in 1,230 jobs and $39 million in labor income. These impacts should be evaluated as a percentage of job loss and labor income to the Lewis Clark Valley economy. The analysis should reflect that these losses may be sustained for approximately 10 years until the river stabilizes and the fish held at the hatcheries are released and later return to spawn. As a mitigation, Lewiston requests direct financial payments until pre-project visitation, jobs and sales return.	The commenter is correct that in the short-term during construction activities, a decrease of 2.3 million water- and land-based visitors in Region C could result in decreased visitor spending of $103 million, a decrease of 83 percent compared to non-local visitor spending under the No Action Alternative, as described in Section 3.11.3.5. Reduced visitor spending would result in a decrease of approximately 1,230 jobs, $39 million in labor income, and $147 million in sales during this construction period. After the construction and breaching period is over, access would be reopened to some of the recreation areas, and it is likely that a portion of the land-based visitors, such as sightseers, hikers, and others, would visit the region after construction while the reservoirs transition to river conditions. For comparison, all economic activity in Region C supports 216,800 jobs, $10.3 billion in labor income, and $31.4 billion in sales annually. As such, adverse effects under MO3 would represent less than one percent of jobs, income, or sales in the region. The mitigation requested for direct financial payments is not within the co-lead agencies' current authorities.
4025	24	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	3-1479 10006 through 10010. Please explain how the agencies will be able to evaluate mitigation success and make adjustments over time if they no longer own the properties?	The Corps requires monitoring and adaptive management to ensure success of mitigation actions. Breaching the four lower Snake River dams would require additional site specific analysis and congressional authorization. A plan for disposal of existing Federal lands would be developed as part of that study.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
4025	25	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	(Page 3-1213) 4-23. Reservoirs have a moderating effect on ambient air temperatures. The agencies recognize the summer water temperatures in a riverine condition will be higher. This coupled with projected power cost increases should be considered a cumulative effect.	The effect of reservoirs on modulating surface air temperature can be observed locally or very near the water body, however, this effect is negligible on resources outside the footprint of the reservoir. Cumulative effects to all resources are analyzed in Chapters 6 and for the Preferred Alternative in Chapter 7.
4025	26	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	5-31 944 through 949. The co-lead agencies do not have authorities for removing in-stream contaminated sediments, and have not identified a feasible way to avoid mobilization. To offset this impact and any associated impacts to bioaccumulation in fish and other aquatic species, other entities could remove or cap contaminated sediment hot spots in the Lower Snake River prior to implementing the Breach Snake Embankment measures. Lewiston believes the deposition of contaminated sediment outside of the original (pre LSRD) floodplain was directly caused by the reservoirs associated with the dams. The federal agencies have an obligation to clean up the soils. The Corps owns the lands under the reservoirs (at least in the Lewiston region), and is the only party who would be allowed to perform this work. Leaving exposed, contaminated soils in the community, trash and debris, may be a violation of Federal,state and local laws. This impact has been identified but no mitigation measures have been presented in the EIS.	If MO3 is identified as the selected alternative in the Record of Decision (ROD), the co-lead agencies would study potential site-specific contamination issues in a National Environmental Policy Act (NEPA) analysis for the implementation of that alternative. However, the co-lead agencies are unaware of any actions on their part that caused a release of hazardous substances into the reservoirs or river that has caused the potential contamination that the commenter identified. The existence of the dam and the fact that sediments are retained by the dam does not create liability for those potential hazardous substances in the sediment. Therefore, even if an evaluation identifies potential contamination in the sediments, without confirmation that the potential contamination was caused by a release of a hazardous substance by the co-lead agencies, the agencies would not have the authority to expend Federal appropriations on a cleanup of contamination that was caused by others. If there are areas where the co-lead agencies are the liable party for the release of hazardous substances into the environment, the co-lead agencies will evaluate and take appropriate actions to address the contamination. This includes areas that the co-lead agencies have already committed to monitoring if MO3 is the selected alternative.
4025	27	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	5-30. Deauthorized project lands are transferred to new ownership. Lewiston requests a map at appropriate scale to evaluate these deauthorized lands and provide appropriate comment.	Federal properties associated with the operation, maintenance, and mitigation for the four lower Snake River dams in MO3 would be transferred through a real estate process in accordance with Federal property laws. If MO3 was selected and authorized by Congress, an implementation plan would be prepared that would include site specific information (including maps) that details the construction, breaching, and disposal actions required to implement MO3, as well as identifying all of the associated permitting for this action.
4025	28	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	5-31 950 through 960. Changes in river flows will cause changes in groundwater flows. This could cause movement from polluted sources of groundwater near Lewiston, Idaho (into the Snake River). This impact has been identified but no mitigation measure has been identified in the EIS.	NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. If MO3 is identified as the selected alternative in the ROD, the co-lead agencies would study potential site-specific contamination issues in a NEPA analysis for the implementation of that alternative. However, the co-lead agencies are unaware of any actions on their part that would cause a discharge of hazardous substances from groundwater into the river. The existence of the dam and the fact that sediments are retained by the dam does not create liability for those potential hazardous substances in the sediment. Therefore, even if an evaluation identifies potential contamination in the sediments or groundwater, without confirmation that the potential contamination was caused by a release of a hazardous substance by the co-lead agencies, the agencies would not have the authority to expend Federal appropriations on a cleanup of contamination that was caused by others. If there are areas where the co-lead agencies are the liable party for the release of hazardous substances into the environment, the co-lead agencies will evaluate and take appropriate actions to address the contamination. This includes areas that the co-lead agencies have already committed to monitoring if MO3 is the selected alternative.
4025	29	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	6-36 827 through 832 Warmer air temperatures combined with decreased summer and fall flow volume could lead to increased riverine and reservoir water temperatures. This could exacerbate algal and nutrient problems, cyanobacterial blooms, and microbial activity at swim beaches; increase pH; and reduce dissolved oxygen within the regions reservoirs and river reaches. This warming could also increase the prevalence of invasive species This impact has been identified but no measures have been presented in the document. Two heavily used swim beaches are located within the Lewiston and Clarkston communities. Under this scenario, we may have none that are safe and pleasant to use.	Chapter 6 identifies those areas that may experience localized increases to water temperature. To implement the Preferred Alternative, there is not an anticipated adverse contribution to increasing temperatures over the No Action Alternative with or without anticipated climate variability. Increased monitoring may be necessary given future climate change and an alternative's effects on water quality, and those instances are identified in Chapter 5 Mitigation. Monitoring for the Preferred Alternative is part of the Monitoring and Adaptive Management Plan (Appendix R).
4025	30	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	6-74 1599 through 1601. Overall, the effects of MO 3 on air quality would most likely be moderate and adverse over the short and long term, primarily in regions C and D. Revegetation of newly exposed soils has been identified as a mitigation measure. What has not been measured or evaluated for mitigation is the contamination of the newly exposed sediments and 45 years of accumulated trash as impacting the success of replanting efforts.	The co-lead agencies agree that appropriate preparation of the newly exposed shorelines and removal of trash would be required prior to any replanting efforts. Any contaminated sediments however would require responsible parties to remediate prior to the co-lead agencies revegetating. Chapter 5 disclosed any known potential hazard of sediments and other discharges into the system that could occur with drawdown and breaching of the four lower Snake River dams as described in MO3. If MO3 were identified as the selected alternative in the ROD, the co-lead agencies would study potential site-specific contamination issues in a NEPA analysis for the implementation of that alternative. However, the co-lead agencies are unaware of any actions on their part that caused a release of hazardous substances into the reservoirs or river that has caused the potential contamination that the commenter identified. The existence of the dam and the fact that sediments are retained by the dam does not create liability for those potential hazardous substances in the sediment. Therefore, even if an evaluation identifies potential contamination in the sediments, without confirmation that the potential contamination was caused by a release of a hazardous substance by the co-lead agencies, the agencies would not have the authority to expend Federal appropriations on a cleanup of contamination that was caused by others. If there are areas where the co-lead agencies are the liable party for the release of hazardous substances into the environment, the co-lead agencies would evaluate and take appropriate actions to address the contamination. This includes areas that the co-lead agencies have already committed to monitoring if MO3 is the selected alternative.
4025	31	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	6-70 Table 6-28. Add Corps has documented fugitive dust generated by strong winds blowing across exposed sediments during dry conditions as being a nuisance.	This requested edit was made in the Final EIS.
4025	32	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	6-87. Under visual impacts, please include mention that what was once beautiful water views will become a barren brown edge along the river for years to come. This impact has not been measured in the EIS so identified mitigation measures can not be confirmed.	The visual resource analysis of MO3 finds that there would be a major effect from breaching the four lower Snake River dams, as described in the Draft EIS, pages 3-1286 to 3-1287. Mitigation for the possible dam breaches have been identified, as described in the Draft EIS, page 5-35, lines 1096-1099. With this mitigation, the major effect on visual quality would diminish over time as the shoreline revegetates and blends into the surrounding landscape. The co-lead agencies have added language to the visual section to better describe this analysis.
4025	33	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	7-71 1817 through 1821. Under the Preferred Alternative, the pattern of outflow changes from Dworshak Dam in January through March would continue downstream. While the percent changes in flow from the No Action Alternative would be pronounced in the Clearwater River system, they would become diluted at the confluence of the Clearwater River and the Snake River near Lewiston, Idaho. The Memorial Bridge on the Clearwater River in Lewiston is now experiencing scour. Lewiston requests that the structural integrity of the bridge be evaluated and mitigated as necessary. D-6-1 4381 through 4383. The sediment study for MO 3 did not include existing bridges and therefore does not consider bridge related scour and deposition potential. This impact has been identified but no mitigation measure has been presented in the EIS.	The U.S. Highway 12 Clearwater Memorial Highway Bridge is located on the Clearwater River approximately 1.5 miles upstream from the confluence of the Snake and Clearwater Rivers. The bridge is supported on multiple piers founded on footings. For this EIS, scour at the Clearwater Memorial Highway Bridge in Lewiston was not considered as requiring mitigation because it was considered as an escalated project cost relative to the 2002 Lower Snake River FR/EIS. In the 2002 study, the potential scour was evaluated at a 500-year flood event flow of 65 kcfs and a water elevation of 733 feet based on Corps river profiles. Estimated potential scour depths were 9 feet. It was estimated that this depth could undermine piers not founded on rock, even though this bridge was in place prior to reservoir impoundment. The 2002 study estimated that pier modifications would be required on Piers 2 through 7; piers 8, 9, and 10 are founded on rock and would not need protection; the existing ground surface of Piers 1 and 11 is at or above the 500-year flood level and, therefore, would not require protection; the 2002 analysis indicated that no abutment protection would be required. The Idaho Transportation Department (ITD) is currently in pre-coordination with USACE regarding the replacement of the existing super structure to provide a widened bridge crossing that meets current standards. Their work includes a geotechnical investigation of bridge pier foundations and scour assessment assuming free-flowing river conditions. The existing piers are supported by spread footings and are expected to stay in place and be utilized to support the new bridge superstructure. The current footings rest on generally competent, granular material, with the exception of Pier 4, which appears to be founded on loose to medium dense gravel. The record plans indicate that the streambed was capable of producing a presumed allowable 10 kcfs bearing capacity. Provisional ITD scour analysis results indicate that formation of channel bed scour holes at the bridge piers would extend below the pier footing bottoms for Piers # 3 9 and would require additional scour mitigation countermeasures. No additional bank protection is anticipated because the existing Lewiston levees constructed by the Corps in 1973 provide sufficient erosion resistance. The ITD report indicates that the pier footings are candidates for strengthening with micropiles. The concrete footings would first be cored and then a micropile would be installed through the footing for a depth of 20 to 40. Utilizing a foundation retrofit technique such as micropiles may also help to remove the scour critical rating for the bridge. Another advantage of using micropiles is that no cofferdam or pumping will need to take place in the waterway, minimizing the impact to the river. Potential alternatives to micropiles include enlarging the current footings or modifying the existing soil properties with a technique such as chemical grouting. These alternative methods would likely result in a larger impact on the river and are therefore undesirable.
4025	34	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	D-6-73 5747 through 5750. Longer term impacts associated with a riverine system may include impacts to groundwater and impacts to point (NPDES) discharges along the River. Lewiston requests that the identified groundwater impacts and point sources be identified and mitigated.	The National Environmental Policy Act (NEPA) requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities.
4025	35	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	F-1-13. Table 1-4. Eleven of the listed plants have been identified by the State of Idaho as noxious weeds. Three are poisonous and one is prohibited. Tangly Ragwort is listed by Nez Perce County as a noxious weed. The city requests aggressive management of newly exposed sediments and planting plans to control for noxious weeds.	The analysis in the CRSO EIS focuses on effects of the operation, maintenance, and configuration of the CRS projects. Effects of this action on vegetation are analyzed in Sections 3.6 and 7.7.7. Outside of the scope of this EIS, the Corps does implement an invasive species management plan on Corps-managed lands as part of routine operations and maintenance and in accordance with applicable Federal laws, regulations, and Corps policy. Management of invasive species is discussed in Chapter 5 under Affected Resources, Sections 5.2.18, 5.4.1.4, 5.4.2.4, 5.4.3.4, and 5.4.4.4; Chapter 6 (Cumulative effects), and Chapter 7 (Preferred Alternative).
4025	36	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	H-1-8 432 through 433. The increased cost of electricity may change household and business spending patterns on other regional goods and services, resulting in a reduction in annual regional economic output (sales) of $320 million to $740 million and cost 2,100 to 4,900 jobs.	The information provided in the comment regarding the regional economic impacts of breaching the lower Snake River dams is consistent with the findings of the EIS.
4025	37	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	K-1-14 Table 1-16. Changes in flood risk annual exceedance probabilities under MO 3 in region C. Region C gage location, action stage flood stages show no change from the no action alternative. According to the Corps Lower Snake River Navigation Maintenance EIS, June 2005 page 4-10 A drawdown/sediment flushing event would likely result in adverse impacts to the Lewiston Levee System. The Hydraulic modeling accomplished utilizing the before and after drawdown conditions supports this statement, showing a rise in the SPF water surface profiles after the 1992 drawdown event. These two statements seem to contradict one another. What will be the impact to the Lewiston levee system? Where are the areas of past seepage located and discussed in the EIS where we can expect slope failures? Who is responsible for repairing slope failures?	The reservoir drawdown/sediment flushing event referenced in the comment has been evaluated previously but is different from the Breach Snake Embankments measure evaluated under MO3. Breaching the four lower Snake River dams under MO3 would eventually scour out legacy sediment deposits, lower the base level to historical river elevations, and reduce flood risk (the Lewiston levees still remain in place). As described in the Flood Risk Management Appendix K, Region C, MO3 would generally reduce river stages from the draining of Lower Granite Reservoir and the breaching of the other lower Snake River dams. Overall, in Region C under MO3, no effect to flood risk is expected. The rate of drawdown and construction over two years in the MO3 alternative is intended to reduce the likeliness of slumping as experienced in the 1992 drawdown event, and it is not anticipated that the Lewiston levee system would be significantly impacted.
4025	38	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	M-2-10 373 through 376. Without the federal reservoir project, the Corps will not have a role in providing recreational facilities; therefore, in order to re-establish recreation opportunities and water access in the region, there would likely be a cost impact to a government agency to provide recreational infrastructure and access roads. This cost is not estimated nor the impact mitigated. Without the impact mitigated, the assumption that a riverine environment will ultimately provide a similar recreational value may not be justified. The Corps could provide adequate mitigation if ownership of the management units/recreation facilities were retained, and access from the upland facilities to the river was constructed. Another mitigation option to Corps ownership could be establishment of a permanent endowment to offset local maintenance costs of the recreational amenities along the levee system.	Chapter 5 in the EIS describes the proposed mitigation measures under each of the Multiple Objective alternatives (MOs) while Chapter 7 describes the mitigation for the Preferred Alternative. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. No Federal mitigation is anticipated under MO3 to maintain access to the river as the Federal agencies would no longer operate the project lands for recreation as the projects would be deauthorized. Recreational sites could be modified in the future as project land is transferred through real estate actions to other agencies and entities. As described in Section 3.11.3.5, access to the river and its recreational opportunities would be paramount for the reestablishment of river visitation to the lower Snake River in the long-term. The EIS generally describes the recreation infrastructure needs (recreation areas, parking lots, access roads, boat ramp extensions, etc.) post dam breach as well as some example costs to extend boat ramps and relocate recreation areas in the region. Post dam breach, it is anticipated that the Corps will not have a role in providing recreation facilities. However, other Federal, state, or local government agencies, or other entities could relocate existing recreation areas or extend boat ramps (from reservoir to river) so that water-based recreation for the river reach could occur in this region.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					If MO3 was selected and authorized by Congress, an implementation plan and associated National Environmental Policy Act (NEPA) analysis would be prepared that would include site specific information that details the construction, breaching, disposal, and mitigation actions required to implement MO3, as well as identifying all of the associated permitting for this action.
4025	39	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	M-3-27 Table 3-10, M-3-28 Table 3-11. Provide no recreational counts for Snake River below Hells Canyon dam. This is the reach of the river with the heaviest usage from the Lewis Clark Valley. Without this data, recreational impacts to the community are greatly underestimated. Idaho State Parks and Recreation commissioned a report by Boise State entitled Economic Impact and Importance of Power Boating in Idaho. The report was released in 2016 and reflects 2015 data. Power Boating generated 18,274 boating trips in Nez Perce County, generating $14,279,660 in direct spending for boats and moorage and an economic value of $22,810,512 annually (pages 10, 12 and 17). This report was not included in the EIS reference section and apparently not considered.	Section 3.11.2.2 describes gaps in the recreational visitation data. Data were not available for all sites, including along the Snake River below Hells Canyon Dam and above Lower Granite Lake. The 2016 report by Boise State entitled Economic Impact and Importance of Power Boating in Idaho was considered for the EIS, but not relied upon directly due to the limited types of visitation data in the report, so it does not appear in the references. In addition, this region was not anticipated to be affected by changes in water surface elevations. The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities.
4025	40	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	M-6-4 line 1028. This section should be expanded to include the loss of resident species with dam breaching. To place this section in context, the agencies should include mention that without the dams, BPA will no longer be legally obligated to support the hatcheries that produce 19 million juvenile fish per year. The combined impact on recreation fishing days with the loss of hatcheries and resident populations has not been measured in the EIS so identified mitigation measures can not be confirmed.	The Draft EIS acknowledges that with the breaching of the four lower Snake River dams in MO3, there would no longer be an obligation for Bonneville to fund the U.S. Fish and Wildlife Service for the operations of the Lower Snake River Compensation Plan hatchery facilities, which account for much of the hatchery production in the basin and other Bonneville-funded mitigation activities could be adjusted. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. Over time, increased returns of wild fish would be expected as wild fish replace hatchery fish, and the Snake River resident fishery would improve as the reservoir habitats transition to riverine. The long-term overall effect of MO3 would be beneficial for Snake River salmon and steelhead as well as resident fish, so no mitigation for this effect was identified. Additional hatchery production would be in place for limited years to offset the short-term dam breaching and construction effects. Mitigation measures are proposed for both anadromous and resident fish as the lower Snake embankments are breached during the transitional period (Sections 5.4.3.2 and 5.4.3.3 for short-term adverse effects). Proposed mitigation includes two years of hatchery production along with trap and haul operations for the anadromous and resident fish during this period. These measures would reduce adverse effects to resident and anadromous fish in Region C. Section 3.11.3.5 describes the impacts to all land- and water-based recreation as major and adverse in the short-term, during and immediately following breaching.
4025	41	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	M-6-4 line 1036 through 1039. Pre-dam river stages under dam breaching would range from approximately 8 to 100 feet below current water surface elevations Existing water-based recreational facilities, such as boat ramps, swimming beaches, and moorage facilities, were designed to operate within very specific ranges of water elevations (generally within 5 feet of full pool). If dam breaching were to occur, none of these facilities could continue to be used without modification or relocation. This impact is addressed but not mitigated. M-6-5 1052 through 1055. Some (recreational) sites would simply cease to be used because the features that attracted people would be eliminated, while other sites would be abandoned because they would be so high above or far away from the river that access would be difficult and possibly dangerous. This impact is identified but not mitigated. M-6-5 1070 through 1073. The stated impact of $8.9 million and $24.5 million in annual economic impacts in the recreation category is underestimated without counts for Snake River below Hells Canyon Dam and is not mitigated. Idaho State Parks and Recreation commissioned a study by Boise State on the Economic Impact and Importance of State Parks in Idaho, January 2018 using 2016 data. Hells Gate State Park had 272,354 visitor days and $6,941,000 in visitor spending, page 41. M-6-7 1126 through 1127. Visitation to the lower snake river would be limited by the availability of infrastructure to access river recreational opportunities. This impact is identified but not mitigated. M-6-9 1189 through 1192. Recreational fishing visitation could be possible in the long-term although there is uncertainty around it being an allowable activity, given the current measures to regulate, protect and support ESA listed fish populations and habitat in the region. The Agencies estimate that the river will take 2-7 years to stabilize (D-6-44). The agencies should also estimate how many years after river stabilization that the runs will support recreational fishing and modify the recreational and economic impacts accordingly.	Visitation to Hells Gate State Park is reported in the EIS (Table 7 in Appendix M). This visitation was incorporated into the regional economic effects analysis under the No Action Alternative (Section 3.11.3.2). Section 3.11.2.2 describes gaps in the recreational visitation data. Data were not available for all sites, including along the Snake River below Hells Canyon Dam and above Lower Granite Lake. Section 5.4.3.6 describes the potential for mitigation measures for recreation under MO3. No Federal mitigation is anticipated under MO3 to maintain access to the river as the co-lead agencies would no longer operate the project lands for recreation as the projects are deauthorized. The mitigation described by the commenter is not within the co-lead agencies' current authorities. Recreational sites could be modified in the future as project land is transferred through real estate actions to other agencies and entities. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the MOs, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which are described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region.
4025	42	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	M-6-11 Table 6-5 note 1, 1234 through 1237. Social welfare effects presented for Regions C and D represent short-term effects. The long-term impacts to visitation is uncertain. Some adaptation is likely over time. To the extent that increases in anadromous fish populations draws additional fishing to the region, increases in regional economic expenditures and effects would increase in the long term. Please provide mathematical evidence of the size of the anadromous fish population that would be needed to offset the loss of resident fish, hatchery production and ESA protections to increase fishing days and when that would occur. Add in the lack of access to the river as noted on M-2-10. Economic impacts can then be fairly evaluated and mitigated. M-6-14 1315-1317. As the river returns to natural conditions, river-based recreation would increase over time, given recreational access and infrastructure is developed. This impact has been identified but no mitigation measure presented in the EIS. Construction of this infrastructure is an appropriate mitigation measure.. This conclusion that recreation will increase contradicts what actually happened when slackwater arrived in Lewiston. As documented by Walla Walla College water activities relating to areas above Granite Lock and Dam have actually risen with the river. Marine-oriented businesses are showing increases of 25-40% from the 1974 levels. A careful check of operators in 1976 indicates that the growth in these businesses has not yet reached its full potential. Slackwater Comes to Clarkston, Washington (A Tale of Two Cities) pg 8. M-6-15 1332 through 1338. Economic impacts and social welfare in the recreation category are estimated at $109 million, 1,420 jobs, $59 million in labor income and $189 million less in sales. The cooperating agencies should mitigate these severe impacts through direct financial support until these jobs, sales and indicators recover to pre-project levels. M-6-16 Table 6-8. Economic impact numbers appear different than those given in the preceding narrative.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11). The recreation analysis for the EIS considered the broad range of recreational activities supported by the region, including recreational fishing. While the analysis describes any potential impacts to recreational fishing visitation, the EIS did not estimate these impacts separately from the overall impacts to recreation, or estimate changes in fishing visitation related to changes in fish abundance. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. Chapter 5 in the EIS describes the proposed mitigation measures under each of the MOs. Section 5.4.3.6 describes the potential mitigation measures for recreation under MO3. No Federal mitigation is anticipated under MO3 to maintain access to the river as the Federal agencies would no longer operate the project lands for recreation as the projects are de-authorized. Recreational sites could be modified in the future as project land is transferred through real estate actions to other agencies and entities. The mitigation requested for direct financial payments is not within the co-lead agencies' current authorities. The EIS recognizes the important contribution that flatwater recreation activities, including motor boats, provide under current water management conditions to the economy of Region C, and also recognizes considerable uncertainty with regard to future recreational activities and associated regional economic effects of those changes. The regional economic effects associated with MO3 in the short-term with the loss of land- and water-based recreation are described in Table 6-8.
4025	43	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	N-3-13 720 through 728. A map should be provided of the well locations that are expected to be impacted by a drop in groundwater elevations. This map should be at such a scale that persons or agencies can identify their specific well location and provide appropriate comments. This impact has been identified in a qualitative way, but no mitigation measure has been presented in the EIS.	There are several maps provided in Appendix N (Water Supply Physical and Socioeconomic Methods and Analysis) and a supporting technical reference called Columbia River Diversions and Irrigated Agriculture Acres (Reclamation 2019). The maps show the possibly affected points of diversion which include both surface diversions and wells within 1-mile of the river. The National Environmental Policy Act (NEPA) requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide mitigation for the effects to private infrastructure such as irrigation pumps, wells, or private docks.
4025	44	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	N-4-19 1294 through 1297. This decrease in household income ($5,849,112) has a negative effect on the regional economy. These impacts were estimated as a loss of 55 jobs, $2,261,000 of labor income and $7,518,00 in output (sales) annually. These severe impacts need to be mitigated.	Chapter 3 analyzes the social and economic effects of implementing this measure. The information provided in the comment regarding the regional economic impacts of breaching the four lower Snake River dams are consistent with the findings of the EIS. While regional impacts such as job loss and changes to household incomes are effects associated with the loss of benefits the dams currently provide, these effects are disclosed in EIS, but there is no identified mitigation within the co-lead agencies' current authorities to offset these effects.
4025	45	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	Q-3-3. Under the dam breaching measures of MO 3, it could be necessary to negotiate agreements with affected parties and property owners and enter into relocation contracts for the alteration or replacement of affected structures. Lewiston would like a specific listing of structures within one mile of city limits the agencies are expecting to need to relocate or replace. We are specifically concerned with the water treatment plant intake, the wastewater plant discharge, the stormwater ponds installed by the Corps, Lindsey Creek and all city point sources; the Clearwater Paper water intake and effluent diffuser; the Corps irrigation system intake along the Snake and Clearwater Rivers. We would like the agencies to identify and evaluate each of these structures. According to the 2002 EIS, the outfall at Lindsey Creek and Memorial Bridge would have to be redesigned and replaced. On the subject of the Corps owned and operated storm ponds near the confluence of the Snake and Clearwater rivers, if they are to be retrofitted, Lewiston prefers a gravity fed system. Pumping would be limited to high flow events. Lewiston supports continued Corps ownership and operation of the ponds.	If MO3 was selected and authorized by Congress, an implementation plan and associated National Environmental Policy Act (NEPA) analysis would be prepared that would include site specific information that details the construction, breaching, disposal, and mitigation actions required to implement MO3, as well as identifying all of the associated permitting for this action.
4025	46	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	Q-5-4 683 through 685. Operation and maintenance activities in the lower Snake River would be considerably reduced compared to the NAA, it would include maintenance of Clarkston and Lewiston levees, law enforcement, and engineering/safety inspections. Corps maintenance, engineering and safety inspections of the levees is important to Lewiston.	If MO3 was selected and authorized by Congress, an implementation plan and associated National Environmental Policy Act (NEPA) analysis would be prepared that would include site specific information that details the construction, breaching, disposal, and mitigation actions required to implement MO3, as well as identifying all of the associated permitting for this action. If MO3 were implemented the Corps would continue inspections of Lewiston and Clarkston levees as part of the ongoing levee inspection program.
4025	47	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	The Corps owned island near the confluence of the Snake and Clearwater Rivers may be subject to scour in a riverine environment and release toxic materials to the Snake River. This impact has not been measured in the EIS nor mitigated.	If MO3 is identified as the selected alternative in the Record of Decision (ROD), the co-lead agencies would study potential site-specific contamination issues in a National Environmental Policy Act (NEPA) analysis for the implementation of that alternative. However, the co-lead agencies are unaware of any actions on their part that caused a release of hazardous substances into the reservoirs or river that has caused the potential contamination that the commenter identified. The existence of the dam and the fact that sediments are retained by the dam does not create liability for those potential hazardous substances in the sediment. Therefore, even if an evaluation identifies potential contamination in the sediments, without confirmation that the potential contamination was caused by a release of a hazardous substance by the co-lead agencies, the agencies would not have the authority to expend Federal appropriations on a cleanup of contamination that was caused by others. If there are areas where the co-lead agencies are the liable party for the release of hazardous substances into the environment, the co-lead agencies will evaluate and take appropriate actions to address the contamination. This includes areas that the co-lead agencies have already committed to monitoring if MO3 is the selected alternative.

4025	48	lvontersch@cityoflewiston.org	City of Lewiston, Idaho	Q-6-5 1000 through 1002. As a result, Bonnevilles F & W program costs were provided as a range under MO 3: from $282 million annually to $177 million annually, (a decrease of $105 million annually compared to the NAA). Losing $105 million dollars annually that had been used to operate hatcheries, improve habitat and fund research is a significant adverse impact. This impact has not been fully measured or mitigation measures presented. Q-C-4 1653 through 1654. Under MO 3, CRS expenditures would decrease relative to the No Action Alternative, with decreases in employment ranging from 961 to 2,822 (-7 to -21 percent). This is a significant adverse impact. This impact has been identified in the EIS but no mitigation measure has been presented. Q-C-5. Table C-3 and Table C-4 go further to quantify the loss of jobs and their value as a low of $239.8 million to a high of $666.7 million. This significant adverse impact needs to be mitigated.	Bonneville's Fish and Wildlife (F&W) Program is estimated to cost $282 million annually, and includes fish and wildlife mitigation projects and studies across the Basin. Funding decisions for Bonneville's F&W Program are not being made through the CRSO EIS process. Future F&W Program funding-level decisions would be made in consultation with the region, through Bonneville's budget-making processes and other appropriate forums and consistent with existing agreements. Based on the inherent uncertainty of Bonneville's F&W Program funding requirements with lower Snake River dam breaching under MO3, F&W Program costs were provided in the EIS as a range, from current levels of $282 million, to $177 million. By analyzing a range of costs, Bonneville reflects the year-to-year fluctuations related to managing its F&W Program and also acknowledges the uncertainty around both the magnitude of biological benefits and the potential impacts on funding, including the timing of funding decisions. Thus, funding decisions are not being made as part of this EIS and would be decided in a future process. Because the outcome of these future processes is unknown, it is too speculative to propose mitigation, so none is proposed at this time. A similar approach was taken for the Preferred Alternative.
4032	1	maxrwilliams@aol.com	N/A	We should be looking at increasing the hatchery rates and adding hatcheries to the area to increase fish population, not breaching dams.	Hatchery programs are included in the No Action Alternative and would be expected to continue under Multiple Objective alternative 1 (MO1), Multiple Objective alternative 2 (MO2), and Multiple Objective alternative 4 (MO4), and certain hatcheries would continue under MO3. No new hatchery programs are considered as mitigation under any alternatives, but MO3 does include increased hatchery production due to short-term impacts from breaching the four lower Snake River dams.
4051	1	Flathead Electric Cooperative	Flathead Electric Cooperative	Today, electricity has become an essential public service and we all need to be mindful that policy changes that adversely impact the FCRPS will result in higher costs for FECs members which puts them at a higher risk that they wont have access to this essential public service. Even prior to COVID-19 pandemic, many of our members struggled to pay their power bill. In Lincoln and Flathead Counties where FEC primarily serves, 16% and 14% of the population respectively lives below the poverty line. Both numbers are higher than the national average.	The comment is consistent with information presented in the EIS. The Environmental Justice analysis in Section 3.18.3 and Chapter 7 provides further detail on potential disproportionate effects to tribal, low-income and minority populations.
4054	1	boswellco@cox-internet.com	N/A	My concern is with the lack of attention in the report of the immense benefits of a Lower Snake River restoration plan. Federal agencies have ignored the importance of salmon and steelhead sportfishing to Idahos river communities, as well as the many outdoor recreation opportunities possible on a restored Lower Snake River.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multiple objectives alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. Under MO3, the EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in Region C that would occur under the measure to breach the four lower Snake River dams as major and beneficial. The potential for increases in recreational fishing under MO3 in Region C is described in Section 3.11.3.5, which would support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The social welfare effects under MO3 on recreational fisheries are described as major and beneficial in the long-term, although there is uncertainty around recreational and commercial fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. However, the EIS does describe that the visitation in the long-term, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting tourism businesses. For MO1, MO2, MO4, and the Preferred Alternative, the recreational fishing evaluation describes the impacts by referencing the potential effects on relevant fish populations, as described in Section 3.5. Aquatic Habitat, Aquatic Invertebrates, and Fish, modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing and associated social welfare and regional economic effects would follow these changes in fish abundance.
4074	1	N/A	N/A	We support the Preferred Alternative (PA) outlined in the DEIS. This could help us avoid further economic turmoil while at the same time, protect fish, birds and other animals covered under the Endangered Species Act (ESA). However, some debate exists about the benefits of allowing spills up to 125 percent of total dissolved gas. There is credible evidence to the contrary. An independent analysis should be completed to determine whether it is detrimental to the fish we are trying to help.	Total dissolved gas (TDG) levels are regulated under the Federal Clean Water Act, and administered by the States. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment, Oregon issued a 5-year "standard modification" and Washington issued a permanent rule change, approved by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects; and therefore, monitoring was required by the states and EPA to ensure that any adverse effects are detected and allow for adaptive management. The Preferred Alternative will require a robust monitoring plan to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored and effects from other sources such as harvest, ocean mortality, and straying will also be accounted for to the extent possible. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
4077	1	Arlene Montgomery	Friends of the Wild Swan	The CRSO EIS states: "The USFWS status review (2008b) reported bull trout were generally stable range-wide, with some core area populations decreasing, some stable, and some increasing. Since the listing of bull trout as threatened in 1999, there has been little change in the distribution of bull trout in the coterminous United States, with the exception of successful reintroduction into the Clackamas River, and occupied bull trout core areas have not been extirpated since the species listing (USFWS 2015)." However, the Bull Trout Five Year Status review painted a different picture than the DEIS characterizes. Substantial or moderate and imminent threats to bull trout, primarily related to habitat impacts, were found to exist in 75 of 121 bull trout core areas (62 percent) during the course of our analysis (USFWS 2005b) and only 13 of 121 core areas (11 percent) were ranked as slightly threatened or unthreatened. These threats occur across nearly the entire landscape (USFWS 2002b), with the exception of only a few core areas that are either wholly or mostly isolated in protected areas. Even in the latter cases, the migratory nature of the species may result in substantial effects during the time or stages of the life cycle when individuals are exposed to habitat impacts outside of these protected areas. The magnitude, severity, and intensity of threats in this category remain high for bull trout across its range. Fragmentation of habitat from dams, water withdrawals, diversion structures, culverts, thermal barriers, and other conditions continues to be a concern with fifty-seven percent of core areas (n=69) across the coterminous range having been characterized as having low to moderate connectivity (USFWS 2005b). Overall, the information indicates that connectivity of habitat within and among core areas is low (USFWS 2005b). Along with the nonnative species threat, the present or threatened destruction, modification, or curtailment of bull trout habitat or range must be considered the most significant determinant of the status of bull trout core areas into the foreseeable future.	The co-lead agencies recognize that threats to the bull trout remain across its range as described in the Bull Trout Five Year Status Review (U.S. Fish and Wildlife Service (USFWS) 2008b) and in the Bull Trout Recovery Plan (USFWS 2015). The 2015 Bull Trout Recovery Plan reported that "bull trout were generally "stable" overall range-wide (species status neither improved nor declined during the reporting year)" (USFWS 2015, p. iii) with habitat loss and fragmentation, interactions with nonnative species, and fish passage issues throughout the range posing primary threats to the species. The co-lead agencies do not disagree with the summary provided within the comment, however, the purpose of the EIS is not to recover ESA-listed species, in this case, bull trout, but rather the consideration of the long-term coordinated operation and management of the CRS projects for multiple purposes under the National Environmental Policy Act. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat for those species. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed bull trout and is not expected to diminish the likelihood of recovery.
4077	2	Arlene Montgomery	Friends of the Wild Swan	Yet the DEIS does not even mention the Primary Constituent Elements (PCEs) that are vital components of bull trout habitat. It does not evaluate how the alternatives will improve or adversely modify the PCEs. The EIS did not address the impacts the dams are having on bull trout and designated critical habitat nor provide workable solutions to protect freshwater native fish. It eliminated from consideration removing dams that are fragmenting and impeding migration. It did not identify the bull trout core areas being impacted by the dams. And whether they are fragmenting habitat, disrupting migratory corridors, or limiting foraging.	The Draft EIS, as a National Environmental Policy Act (NEPA) document, is intended to evaluate alternatives compared to the No Action Alternative. The co-lead agencies recognize the elements vital to bull trout habitat and many of the factors mentioned are discussed in the Affected Environment and No Action Alternative. In the alternatives analyses, these were evaluated as to how the various alternatives would affect those habitat elements and relationship between those elements and the species. In the Preferred Alternative, a number of measures were included to improve conditions for bull trout and other resident fish species. The Biological Assessment is included as Appendix V for additional information on the effects analysis for the proposed action specific to ESA-listed species. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to meet the requirements of Section 7(a)(2). Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Appendix V of the Final EIS includes the Biological Opinions issued by NMFS and USFWS demonstrating ESA compliance.
4077	3	Arlene Montgomery	Friends of the Wild Swan	We did not see an analysis of the impacts to wildlife and riparian areas from dam operations, not just construction. Riparian vegetation can be wiped out by fluctuating flows leading to erosion (water quality issues), sediment in gravels, loss of shade, increased water temperature, lack of cover for wildlife, reduced food sources (i.e., insects), impacts to amphibians and birds.	The vegetation assessment included evaluation of impacts to riparian vegetation based on inundation, erosion, and sediment deposition as well as potential impacts to wildlife as a result of vegetation changes (i.e. food, cover, and impacts to amphibians and birds). This assessment can be found in Section 3.6 (Vegetation, Wetlands, Wildlife, and Floodplains) and in Section 7.7.7 for effects of the Preferred Alternative on Vegetation, Wetlands, Wildlife, and Floodplains.
4077	4	Arlene Montgomery	Friends of the Wild Swan	The EIS did not address the protection of floodplains and channel migration zones, adequate streamside/riverside buffers to protect and improve water temperatures, re-regulating water withdrawal infrastructure to protect instream flows from overexploitation and restore migratory connectivity. Similarly dam operations must not increase water temperatures. Selective water withdrawals may alleviate this problem. There was some discussion in the EIS about selective withdrawal infrastructure but it seemed piecemeal and not part of a cohesive strategy. Bull trout rely heavily on upwelling groundwater that keeps water temperatures cold. Floodplain protection and restoration actions on larger alluvial streams and rivers were not included to protect or re-establish the natural exchange and underground storage of surface and subsurface waters that naturally recharges shallow alluvial aquifers and buffers summer and winter water temperatures against extremes.	Several of the issues that the commenter suggests addressing are outside of the scope of the operations and maintenance of the CRS EIS. The EIS is intended to evaluate alternatives compared to the No Action Alternative. Important elements that could be affected by the projects, such as temperatures and habitat elements, were evaluated to compare the alternatives to the No Action Alternative. The co-lead agencies recognize the elements vital to bull trout habitat and many of the factors mentioned are discussed in the Affected Environment and No Action Alternative. In the alternatives analyses, bull trout were evaluated as to how the various alternatives would affect those habitat elements and relationship between those elements and the species. Under the Preferred Alternative, a number of measures were included to improve conditions to bull trout and other resident fish species. Section 3.6 and Chapter 7 analyzes the impacts from the alternatives to floodplains. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet authorized purposes while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
4077	5	Arlene Montgomery	Friends of the Wild Swan	Climate change impacts on water temperature, quantity and quality is of utmost importance but is scantly covered in the DEIS. The Montana Climate Assessment (see montanaclimate.org) drew some key findings: "The results of this analysis produced several key messages, some of which are shown below, about how climate change will affect Montanas water resources (for a complete list of key messages, see the Water chapter). Rising temperatures will reduce snowpack, shift historical patterns of streamflow in Montana, and likely result in additional stress on Montanas water supply, particularly during summer and early fall. Key messages associated with these findings follow: Montanas snowpack has declined over the observational record (i.e., since the 1930s) in mountains west and east of the Continental Divide; this decline has been most pronounced since the 1980s. [high agreement, medium evidence] Warming temperatures over the next century, especially during spring, are likely to reduce snowpack at mid and low elevations. [high agreement, robust evidence] Historical observations show a shift toward earlier snowmelt and an earlier peak in spring runoff in the	Chapter 4 includes a discussion on the potential impacts that future climate change may have on resources including water quality and quantity. The co-lead agencies agree that climate change is a concern. The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at the required resolution (river-scale vs. global- or regional-scale) at this time. Therefore, it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature and other water quality parameters (Section 4.2.3). Specific information in the Draft EIS on climate effects to hydrology and hydraulics can be found in Section 4.2.1, and how climate impacts water supply can be found in Section 4.2.9 and Section 7.8.1 (hydrology and hydraulics) and 7.8.12 (water supply).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Mountain West (including Montana). Projections suggest that these patterns are very likely to continue into the future as temperatures increase. [high agreement, robust evidence] Earlier onset of snowmelt and spring runoff will reduce late-summer water availability in snowmelt-dominated watersheds. [high agreement, robust evidence] Groundwater demand will likely increase as elevated temperatures and changing seasonal availability of traditional surface-water sources (e.g., dry stock water ponds or inability of canal systems to deliver water in a timely manner) force water users to seek alternatives. [high agreement, medium evidence] Rising temperatures will exacerbate persistent drought periods that are a natural part of Montanas climate. Key messages associated with these findings follow: Multi-year and decadal-scale droughts have been, and will continue to be, a natural feature of Montanas climate [high agreement, robust evidence]; rising temperatures will likely exacerbate drought when and where it occurs. [high agreement, medium evidence] Changes in snowpack and runoff timing will likely increase the frequency and duration of drought during late summer and early fall. [high agreement, medium evidence]	
4102	1	N/A	N/A	A key component of the preferred alternative MO4 is flexible spill, but studies by the Fish Passage Center have clearly shown that this practice is inadequate as a long-term strategy, and does not produce salmon survival benefits that are needed from the Columbia / Snake River dams.	Multiple Objective alternative 4 (MO4) was not identified in the Draft EIS as the Preferred Alternative. The Preferred Alternative included measures from various alternatives after consideration of beneficial and adverse effects of various measues. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The CSS model predicts that average Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
4109	1	cwyatt@bbec.org	Big Bend Electric Cooperative	The cost to replace the essential energy-related capabilities of the lower Snake River dams with other zero-carbon options would be approximately $1 billion annually and would likely increase the average residential electric bill of our rural members by 20% or more. BBEC serves the rural areas of Adams and Franklin Counties. Most of area in these counties is already economically depressed and many members would have trouble with increased costs of an essential service.	The comment that replacing electricity generation from the four lower Snake River dams under MO3 would drive up costs in the region is consistent with EIS findings. See Draft EIS, Section 3.7.3.5, Table 3-166; and Appendix H, Table 2-1. The Environmental Justice analysis in Section 3.18.3 provides further detail on potential disproportionate effects to tribal, low-income and minority populations. Section 3.7.3.5, Residential Effects, page 3-929 in the Draft EIS, and Chapter 5 of Appendix H, Power and Transmission provides additional details on potential increases in rate pressures by county as well as for urban and rural utility customers.
4109	2	cwyatt@bbec.org	Big Bend Electric Cooperative	Additionally, the report shows that if the dams were replaced with natural gas resources, it would add an additional 3.3 million metric tons (MMT) of CO2 to the region each year--a 10% increase in the regions power-related emissions. However, it is very unlikely that any new carbon based generation could be permitted in Washington State where these dams are located since the passage of the 2019 Clean Energy Transformation Act. According to this law, all electric energy sold in Washington must be carbon-free by 2045. Regardless of how the electric generation would be replaced, the loss of the transportation barges on the lower Snake River would cause an increase in semi-truck traffic on two lane county roads and rail traffic which would in turn, increase CO2 emissions. This is in direct conflict with the Clean Energy goals of Washington State. The lower Snake River dams are vital for their flexibility to help safely add new intermittent resources, such as wind and solar power to the grid. The dams can store water and release it Page 2 of 2 past hydro turbines, when needed, such as during the night and on calm days, keeping the grid in perfect balance a requirement of science, not politics. The flexible capacity that the dams provide will only increase in need and value as the regions various state legislations and policies continue to drive the retirement of fossil-fueled base load resources and replace them with intermittent renewable generation.	The information in this comment is consistent with the findings of the EIS. A 3.3 million metric tons (MMT) CO2 increase in greenhouse gas (GHG) emissions under MO3 (a 8.9 percent increase in regional power sector emissions) is associated with a scenario in which only natural gas resources are developed or acquired to offset losses from the four lower Snake River dams. As discussed in the EIS, the analysis additionally considers a scenario assuming all renewable replacement resources (at a higher cost is discussed in Section 3.8). Under this scenario, the analysis finds a 2.7 percent increase in regional CO2 emissions relative to the No Action Alternative. Given that policy and legislative decisions in Oregon and Washington are targeting large reductions in GHG emissions, even the 2.7 percent increase in CO2 emissions makes these goals more difficult to achieve.
4109	3	cwyatt@bbec.org	Big Bend Electric Cooperative	The D-EIS estimates that dam breaching would result in $458 million from the inability to irrigate farmland. That is a large amount of dollars, but it doesnt account for the intangible losses to those families homes and livelihood. These communities, already in economic depressed counties, anticipate that the effects would ripple through education systems, social welfare programs, and local economies as a result of increased costs and job losses.	Along with describing the changes in irrigated acres, the EIS describes the regional economic and other social effects of these changes. As reported in the regional economic effects sub-section for Region C in Section 3.12.3.4, decreased production from loss of irrigated farmland would effect 4,800 jobs and decrease labor income from $232 million.
4114	1	N/A	N/A	The Montana Operations at Libby and Hungry Horse balance hydropower generation, flood management, and ecosystem benefits that improve conditions for resident species and their habitats without adversely affecting downstream and anadromous species. The inclusion of the Montana Operations in the CRSO EIS and the incorporation of future science-based improvements into this operational strategy are vital to continuing our shared progress toward improving riverine and flood plain habitats for resident fish and wildlife species. We appreciate the willingness you have shown to date to work with us to adjust annual operations and we look forward to your continued collaboration on these efforts, particularly on ways to improve flow patterns to benefit the overwinter survival of cottonwood stands and to promote burbot and sturgeon spawning and recruitment. Efforts such as these are vital in ensuring the CRSOs ability to provide both reliable power supplies and the ecological functions so critical to our fish and wildlife resources. These operations, of course, also remain integral to current and future Biological Opinions for endangered Kootenai white sturgeon and threatened bull trout and provide a sound basis for the future Columbia River Treaty.	The co-lead agencies also look forward to continued collaboration on the operations of these reservoirs. Elements of the Montana Operations have been incorporated into the Preferred Alternative and will be implemented in collaboration with our partners.
4118	1	mggerdes89@gmail.com	N/A	Your website required us to review 270 megabytes (over 5,000 pages) of information from a website to understand the entire proposal. Yet the co-lead agencies have made it extremely difficult to almost impossible to file comments online or hand-deliver comments. The filing online is limited to a maximum of 100 kb with no more than 5 attachments of 2 megabytes apiece. Therefore adding a few pictures, graphs or diagrams takes us over the 10 megabyte maximum very quickly. We have filed comments with many other federal agencies including the US Forest Service and US Bureau of Land Management and have never encountered such obstructive difficulties in filing comments. This is absolutely an unfair NEPA process to limit public comments in both manner and size limit. Further, when a friend tried to hand deliver comments to the one place in Portland, Oregon designated to take hand delivered comments, the place was locked to the public. When the person was able to finally use a call box outside, everyone she talked to in the building was clueless about the filing of a hand delivered document. This is completely unacceptable for 3 public agencies to make filing a document so challenging and difficult. We are including this problem in our comments to you so that the judge for this case will be aware of the difficulties you have made it for the public to file comments on this Draft EIS.	The co-lead agencies are sorry for any technical difficulty experienced. It is accurate that the website had file size limitations that were listed for a single entry. That was not to limit you in your comments, but to alert you to submit in multiple entries either contact the CRSO info helpline, or mail your materials to the P.O. Box listed on the CRSO website and on other news and informational releases. Hand delivery was not an option for public comments, and unfortunately with the COVID-19 pandemic response, the co-lead agencies would not have been able to accommodate you should we have had this request, as many office buildings were closed and personnel were directed to work from home. All comments mailed with the post-marked dates prior and up to April 13, 2020, or delivered by a delivery service with access to the mail room by 5:00 pm on April 13, 2020, were accepted.
4118	2	mggerdes89@gmail.com	N/A	The Low Amount of Energy Produced at the Lower Snake River Dams The 4 lower Snake dams together produce an average of 3.3% of the annual Pacific Northwest power supply. Yet the regional power surplus including breaching of the lower Snake dams is approximately 13.7%. A review of the regional energy load is that under critical, average and high-water years, the projected surplus from load generation is 3 to 4 times the average lower Snake River production. Essentially, even if the 4 lower Snake dams are breached, even under critical low water conditions, the Pacific Northwest region has an energy surplus. The Northwest Power and Conservation Council (NWPCC) projects additional power resulting solely from efficiency gains in 2020 will be 1000 aMW, which is a little more than the average annual output of the 4 lower Snake dams in the last 5 years. The CRSO-DEIS Executive Summary claims that Significant quantities of replacement resources would have to be built to maintain regional power reliabilitythe region would face the likelihood of a loss of load event, e.g. a power blackout, nearly one in every seven years in MO3, (CRSO-DEIS, Executive Summary, page 25). These claims are specious because the generation from the 4 lower Snake River dams is relatively significant, there is a surplus energy supply, there are increasing alternative energy sources from wind and solar, there are increased energy efficiencies, and blackouts are unrelated to lower Snake River dam outputs. More specifically, the Pacific Northwest wind power plants produce nearly three times the combined generation of the 4 lower Snake dams. Montana has new wind power projects which are predicted to produce up to 5000 aMW by 2030 and are targeted for export to the Pacific West Coast states. Additional projects in Oregon such as the Wheatridge project will include 292 turbines with a peak capacity of 500 aMW and proposes wind, solar and battery backup to offer firm power. California once was a major buyer of BPAs surplus power and is adding an 14,000+ aMW of new solar energy to its own energy portfolio between 2018 and 2023. With the addition of wind and solar energy and other states producing more power and importing less BPA surplus power, the value of the 4 lower Snake River dams for generation is obsolete. These dams cost more to produce and maintain power than the value of the power for sales. Taxpayers and ratepayers are paying for obsolete dams that the co-lead agencies falsely claim are necessary. The co-lead agencies use of the 4 lower Snake River dams energy production to rationalize allowing native salmon and steelhead to go extinct is another false justification to avoid a decision to not breach the lower Snake River dams.	The comment suggests that the regional supply of power is sufficient without the output of the four lower Snake River dams, and even sufficient without replacing the output of the lower Snake River dams with other resources. The comment reaches this conclusion by comparing the average resource output for the remaining regional resources (without the four lower Snake River dams) with average load in the region. Such an approach, however, only demonstrates that on average that is under average conditions - all power system needs would be met. This approach does not address conditions other than average. That is, regional demands for power would not be met at times of greater than average load or lower than average resource output. In those instances, power system emergencies or blackouts would occur. The EIS uses a more robust measure of power system reliability and resilience than the average MWs approach suggested by the commenter. Specifically, the EIS uses the loss-of-load probability (LOLP) metric utilized by the Northwest Power and Conservation Council (Council). See Draft EIS Section 3.7.2.2; Appendix H Power and Transmission, Section 2.1; Appendix I Hydroregulation, Section 2.4.4. The LOLP metric evaluates the adequacy of power supply in the region to meet firm power needs under various conditions. It is measured in terms of a percentage, and represents the likelihood of a year having one or more blackouts. See Appendix H Power and Transmission, Section 2.1. The current LOLP under the No Action Alternative is 6.6 percent; this is equivalent to one year with blackouts in every 15 years. The EIS uses this LOLP level as the benchmark from which to evaluate the other Multiple Objective alternatives (MOs). Under MO3, on average, the region has surplus generation leading to export sales during certain periods and water years. Nevertheless, to maintain regional reliability at the LOLP levels of the No Action Alternative, replacement resources would be needed. This is driven by the timing and magnitude of changes in hydropower generation analyzed in the EIS. As shown by the analysis of the LOLP, in some years and times of the year, particularly winter and later in the summer of drier years, without the four lower Snake River dams there would be insufficient power supply in the region leading to power emergencies and blackouts. Specifically, without replacing the power from the four lower Snake River dams, the LOLP of the region would more than double to 14 percent, which is equivalent to one year with blackouts every seven years. See Draft EIS page 3-903; and Appendix H Power and Transmission, Table 2-1. The commenter also presumes that the power produced from the four lower Snake River dams is surplus and exported out of the region. The power output for the four lower Snake River dams are not exclusively sold as surplus as the commenter suggests. Bonneville sells power from the Federal Columbia River Power System (FCRPS) as a unified system, not from specific projects. In this regard, the power generated from the four lower Snake River dams are pooled with all other FCRPS power sold by Bonneville to meet Bonneville's collective power obligations. Most of this power is used to meet the loads of regional publicly owned utilities, such as municipalities, rural utilities, and public utility districts under long-term power-sales contracts (see Draft EIS Section 3.7.2.5 Bonneville Power and Transmission Customers). A small portion of power is sold in the California energy market, but these sales are not from specific projects, but rather from the collective FCRPS. The references to a regional surplus does not take into account the accelerated loss of coal from the region in coming years. The EIS relied on existing coal retirements for its analysis. See Draft EIS, Section 3.7.3.5, page 3-841; and Appendix H, Section 2.3. As discussed in these sections, with accelerated coal retirements the region would likely experience a significant regional deficit of power, which will require adding additional power resources to maintain power system reliability at the No Action Alternative levels. See Draft EIS Sections 3.7.3.3 through 3.7.3.6; Section 3.7.3.5, Potential Replacement Resources and Associated Costs; and Section 3.7.3.2, Table 3-123. While the comment is accurate that additional renewable power development is occurring across the region, the EIS findings do not concur with the commenters conclusion that the four lower Snake River dams are unnecessary with the influx of new solar and wind. As discussed in Section 3.7.2.2, Power System Flexibility and Reliability, system reliability is maintained by relying on generating capacity that is dispatchable, meaning it is able to change on demand to meet fluctuations in supply

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					and demand. Solar and wind resources are generally not dispatchable because their output is dependent on the availability of wind or sunshine. Hydropower and natural gas are dispatchable because they can adjust production within minutes or seconds. The EIS describes how this dispatchability is provided through balancing reserves to meet system uncertainty and to integrate renewable resources, such as wind and solar. See Draft EIS, Section 3.7.2.2, Meeting System Uncertainty with Generation Balancing Reserves, Dispatchable Resources, and Ramping Capability. As explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are connected to Automatic Generating Control (AGC), making them among the few projects that are capable of providing balancing reserves. See Draft EIS, Section 3.7.3.5, Value of Lower Snake River Dam Ramping Capability. The four lower Snake River dams currently carry approximately 20 percent of upward flexibility and 8 percent of the downward flexibility held by the FCRPS for balancing reserves. Replacing hydropower generation with solar and wind does not replace the dispatchable characteristics of the four lower Snake River dams. Indeed, the EIS found that the demand for the dispatchable capability of the four lower Snake River dams would be needed to provide the balancing reserves to integrate additional wind and solar in the region. See Draft EIS, Section 3.7.3.5, Integration Services, page 3-832. It is true that Bonneville sells and buys power from California. While California continues to expand its fleet of renewable resources such as wind, the expectation is that power would continue to be traded between the regions as demand and generation are dynamic. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four lower Snake River dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170, Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review (see Footnote 1 below) , the Headwater/Lower Snake Asset Class (see Footnote 2 below) is forecast to have a 50-year levelized cost of generation (see Footnote 3 below) of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. Footnotes: 1. The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2. In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3. Levelized Cost of Generation is defined as the forecast direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
4118	3	mggerdes89@gmail.com	N/A	An Outdated Freight System East/west freight using the Columbia and Snake river transportation system has declined dramatically in the past 10-20 years. Container freight movement from the Port of Lewiston has dropped to zero since 2000. In addition, the transport of wheat has steadily dropped since 1995. All wheat at Lewiston is now shipped via a private corporation at its own docks and total lower Snake River freight volume has dropped 40% since 2000. Paper, pulp, petroleum, pulse, logs and lumber are no longer shipped on the lower Snake River while increasing numbers of grain growers have shifted to rail transport. All river transport to Lewiston could be changed in a onetime cost to rail transport, of which many exporters have already done so. For example, all waterborne freight from Lewiston locks through Lower Granite Dam. In 1994, 1,233 loaded barges locked through Lower Granite, while only 314 barges locked through in 2017, a decrease of 75%. In fact, compared to waterways throughout the country, the lower Snake Rivers value as a transportation waterway is insignificant. The co-lead agencies use of lower Snake River freight transportation to rationalize allowing native salmon and steelhead to go extinct is fictitious, costly, and unethical and is another false justification to avoid a decision to not breach the lower Snake River dams.	Access to barge transportation is the most cost effective means of accessing export markets for many of grain producers in the Pacific Northwest currently and removing that option would increase transportation costs for grain producers, as the EIS shows. This is different than container shipping, which the co-lead agencies acknowledge the decline to zero of container traffic on the lower Snake River in Section 3.10. It is true that barge movements on the Snake/Columbia river have declined somewhat over the past 20 years, but not by 70 percent. The co-lead agencies concur that upriver traffic seldom moves through any of the four Snake River dams, as is already discussed in the EIS. The co-lead agencies' working level of traffic for the model was 2.4 million, which reflects the average over the past 10 years. While it is true that the Snake River freight volume is certainly smaller than the volume of the Mississippi and Ohio River systems, it is nonetheless an important transportation option for a large volume of freight, particularly for farm products, with the Columbia-Snake River system serving as one of the largest exporters of farm products in the U.S., and the largest exporter of wheat. The EIS finds that transportation of freight that is currently barged on the Lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investments in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. These effects are considered in the context of the overall objectives of the EIS. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3 by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams because the Preferred Alternative is more likely to satisfy multiple complex legal requirements for a complex system.
4118	4	mggerdes89@gmail.com	N/A	The U.S. Congress authorized the USACE and Bureau of Reclamation to construct, operate, and maintain the system projects to meet multiple specified purposes, including flood control. The Executive Summary asserts that the Preferred Alternative ensures that human life and safety can be protected through flood risk management (CRSO-DEIS Executive Summary, page 32). However, the 4 lower Snake dams are not flood control dams but are run-of-the-river dams with little reservoir space for fluctuating water levels and with virtually no storage capacity, excepting perhaps a few hours of storage during peak flow. Essentially, the 4 dams do nothing to control flood risk in downstream reaches but conversely they create flood risk in Lewiston, Idaho and Clarkston, Washington. The reservoir created by Lower Granite Dam backs up water 40 miles to Lewiston and Clarkston, which are at the confluence of the Snake and Clearwater rivers. Large levees have been built there to prevent overflooding from the Lower Granite Dam reservoir which has sediment buildup, which typically occurs at the inflow of reservoirs. The accumulation of sediment at Lewiston and Clarkston is a continuous and costly problem that creates flood risk for these communities. Breaching of the 4 lower Snake Dams would eliminate sediment buildup, reduce flood risk, make the communities at Lewiston-Clarkston safer from flooding, and eliminate the high costs of continuously needing sediment dredging. The co-lead agencies use of the argument of flood control and safety for selecting the Preferred Alternative and avoiding the breaching of the 4 lower Snake River dams is another fabrication of bogus information to support a false conclusion. Breaching of the 4 lower Snake River dams would have no effect on flood control for river reaches downstream of the dams because they are run-of-river dams. Breaching the dams would reduce the risk of flooding that occurs in Lewiston and Clarkston. Therefore, breaching the 4 lower Snake River dams would save Snake River salmon and steelhead while eliminating risk from floods and increasing community safety.	The commenter is correct that MO3 which includes a measure to breach the four lower Snake River dams would eliminate sediment buildup and reduce flood risk at the confluence area of the Snake and Clearwater rivers (clarifying information has been added to Appendix K.1.7.3.). However in general the four lower Snake River dams are not authorized for flood risk mitigation, and there is no elevated risk to flooding in the Lower Snake River reach for any of the alternatives. The commenter is correct in that the lower Snake River dams are not authorized for flood risk management and this is clearly stated in the EIS in Section 1.2.Chapter 7, Table 7-1, also indicates that there is no elevated risk to flooding in the lower Snake River reach for any of the alternatives. Unlike free-flowing channels, in Lower Granite Reservoir, the forebay elevation at the dam controls the energy grade-line of the water surface, and the reservoir is drawn down during high water events to ensure water levels remain low. Furthermore, the Corps Walla Walla District constructed eight miles of levees around Lewiston as mitigation to help protect lives and property from potentially destructive high-water conditions after the dams were built. Unlike freely flowing channels, in Lower Granite Reservoir the forebay elevation at the dam controls the energy grade-line of the water surface, and the reservoir is drawn down during high water events to ensure water levels remain low. The most recent dredging in the Lewiston area, has been to maintain a 14-foot depth in the navigation channel, as discussed in the 2014 Programmatic Sediment Management Plan. Dredging outside of the navigation channel limits to maintain conveyance capacity has not been conducted since 1992. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3 by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
4118	5	mggerdes89@gmail.com	N/A	The CRSO-DEIS Executive Summary (page 24) states, breaching the dams would not allow the co-lead agencies to operate and maintain the dams for their congressionally authorized purposes of navigation, hydropower, envisioned recreational benefits, and water supply for irrigation purposes. The needs of fewer than two dozen irrigators which are all located on the Ice Harbor Reservoir are touted as one of the many reasons to maintain the 4 lower Snake River dams. For some unknown reason, the co-lead agencies assume that if the dams are breached, that 47,926 acres would no longer be irrigated at a social welfare cost of $458 million. That assumption is false on the face of it, since the river itself would remain available for irrigation. A one-time expense of aid to farmers to upgrade pumps and lengthen water lines would ensure much of the 47,926 acres are irrigated post-breaching. Further the CRSO-DEIS fails to acknowledge the importance of restoring fall Chinook spawning habitat and 15,000 acres of prime riverine habitat and agricultural land that is inundated by the lower Snake River dams.	The MO3, which includes breaching the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams would reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected. The EIS describes the engineering solutions for irrigation (pipeline extensions, for example) in Section 3.12.3 Environmental Consequences under Region C for MO3. The EIS describes that modifying the existing pump system was cost prohibitive. In Region C for MO3, it is assumed that pumps are unable to deliver water to an estimated 47,926 acres.
4118	6	mggerdes89@gmail.com	N/A	The High Cost of the Hydro System Lower Snake River Dams The Bonneville Power Administration (BPA) is the federal agency that markets the dams power output, and the intent was to turn cheap electricity into a cornerstone of the regional economy. BPAs mission was realigned in 1980 under the Northwest Power Act to both maintain the reliability of power production and find the regional effort to recover wild salmon and steelhead. Currently, a third of the main-stem Columbia dam infrastructure has exceeded its design life, and shutdowns have pushed the systems reliability below the hydroelectric industry average. While much of the power is sold to public utilities under 20-year contracts, revenue to BPA has declined due to expanding wind, solar, and natural gas plants that have reduced energy prices in western markets. All the funds spent on restoring wild salmon and steelhead, including building and maintaining large fish hatcheries (intended to provide harvest or support wild fish restoration), barging juvenile salmon and steelhead, spilling water to support downstream juvenile migrations, improving juvenile bypass systems, and other programs, have failed to salvage declining salmon and steelhead runs. All of the Snake River salmon and steelhead runs are federally listed under the Endangered Species Act (ESA) as endangered or threatened and have been so for almost 30 years. Meanwhile, BPAs financial problems have increased as the agency has drawn from cash reserves and borrowed from private lenders and the U.S. Treasury with debt reaching $15 billion dollars. BPA has spent most of its reserves and faces large debt for required but unfunded retrofits and replacements to the turbines in the 4 lower Snake River dams (Figure 1). Figure 1. Rising maintenance costs of the US Army Corps of Engineers dams in the Columbia River basin1 . Since 2008 in response to revenue losses, BPA has drawn down its fiscal reserves from $917 million in 2007 to a fragile $5 million in 2017. BPAs historic revenue stream relied partly upon surplus energy sales. Yet, development of other energy sources in places such as California to which BPA previously sold surplus at a profit has rendered BPAs surplus power	Bonneville's revenues have not declined over time, but less of Bonneville's revenue requirement is covered by net secondary sales of surplus power due to an industry-wide decline in market prices for wholesale power, which has required rates to firm requirements customers under long-term contracts to increase. In light of these competitive pressures, Bonneville developed both strategic and financial plans to ensure Bonneville's rates continue to be competitive. See Draft EIS, Section 3.7.2.5, pages 3-801-802 and Section 3.7.3.1, pages 3-842-843. Bonneville has instilled a renewed focus on cost management discipline, resulting in a cost reduction of $66 million per year for the current rate periods operating costs compared to the last rate periods operating costs. This resulted in an average 0% base rate increase for power customers at a time when the general economy was facing material inflationary pressure. Bonneville's cost management discipline, and revenue enhancing activities continue to maintain Bonneville's competitiveness relative to other load serving power producers. However, analysis of removing the low cost four lower Snake River dams, which includes assumptions of expected operation and maintenance (O&M) and capital investment in the dams, demonstrates substantial upward rate pressure for Bonneville customers, moving Bonneville's competitive power products to be less competitive in the marketplace. See Draft EIS, Section 3.7.3.5, Table 3-166. The financial reserves figures described in the comment are inaccurate. As of the end of 2019, Bonneville's collective financial reserves were $731 million, not $5 million. Bonneville implemented the Financial Reserves Policy (FRP) alongside BP-18 rates, which added new tools to maintain Bonneville's financial health, including the FRP Surcharge, which adds revenue recovery above costs to rebuild Bonneville's financial reserves. The comment also suggests that with additional surplus energy and declining market prices on the wholesale power market, the region must also have a surplus of power for load service. However, the Loss of Load Probability (LOLP) studies used in the EIS indicate that, while the region has substantial amounts of energy on an interim basis due to renewable buildout supported by government legislation, there is a deficit of flexible and dispatchable resources needed to meet growing resource variability and ramping requirements associated with more extreme load shapes. And, the entire power and transmission rate analysis shows that building new resources to replace the lost flexibility is expensive. See Section 3.7.3.5, Lower Snake River Full Replacement Used in Rate Sensitivity Analysis, beginning on page3-905 in the Draft EIS. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				no longer in high demand. BPA is now obligated to sell the surplus power at negative prices. More specifically, the price of surplus power averaged about $60 per Megawatt hour (MWh) prior to 2009. Since 2009, the average price for surplus power has been about $22 per MWh. Revenue has consequently dropped dramatically as a result of drop in price. BPA began raising the price of power for its contracted users and over the last 8 years has increased prices by 30%. Further large expenses are for rehabilitating and replacing aging turbines in the 4 lower Snake River dams. All of the turbines as of 2020 are 40-50 years old and the USACE has stated that 1 Bernton, Seattle Times Report, July 21, 2019 4 Stuart and Gerdes Comments on CRSO-DEIS April 9, 2020 the life of each turbine is 35-45 years. They all need to be replaced. If the same costs are expected as turbine rehabilitation at McNary Dam on the Columbia River is true at the lower Snake River dams, then the estimated cost of replacement of 21 lower Snake River dam turbines exceeds $1 billion. Given that these dams provide little power in an energy surplus situation, the likelihood of replacement of these turbines is nil. The co-leads use of the 4 lower Snake River dams energy production to rationalize allowing native salmon and steelhead to go extinct is a false justification to avoid a decision to not breach the lower Snake River dams.	replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four lower Snake River dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in Multiple Objective alternative 3 (see Table 3-170, Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review (see Footnote 1 below), the Headwater/Lower Snake Asset Class (see Footnote 2 below) is forecast to have a 50-year levelized cost of generation (see Footnote 3 below) of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. Footnotes: 1. The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2. In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3. Levelized Cost of Generation is defined as the forecasted direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric. Although the turbines at the four lower Snake River dams are between 41 and 50 years old and nearing their design lives, there are no plans for any immediate replacements. Investment decisions are driven by equipment condition, probability and consequence of failure and, as such, it is common for equipment to be in service well past its design life. For example, some turbine runners at McNary dam will be over 70 years old by the time the replacement project is complete. Long-term planning analyses that calculate the optimal economic time to replace equipment based on current and expected equipment condition, probability of failure and outage consequence, point to the late 2030s as the earliest replacement dates for major powertrain equipment at the four lower Snake River dams. Most turbine replacements are forecasted between the 2040s and 2060s which would put the turbines at the four lower Snake River dams at about the same age at replacement as McNary.
4118	7	mggerdes89@gmail.com	N/A	Th co-lead agencies speciously claim a per-dam survival rate of approximately 95% (CRSODEIS Executive Summary, Figure ES-4, page 19 and Chapter 3, Figure 3-113, page 3-302), which sounds good on the surface. However, it fails to account for cumulative losses at all projects which are not additive but multiplicative. Studies have demonstrated that cumulative losses approach 50% for downstream migrating juveniles from Lower Granite Dam to the tailrace below Bonneville Dam, while delayed mortality below the hydro system causes additional mortality. Upon reaching the Columbia River estuary and Pacific Ocean, survival rates for juveniles from Lower Granite Dam to the ocean are typically less than 20%. Smolt-to-adult ratios (SARs) are the best benchmark for measuring survival since these ratios measure survival from the downstream migrating juvenile to the returning adult. A SAR of 2-6% is needed to assure the survival of a fish species and these SARs are the regional recovery goals of the Northwest Power and Conservation Council. However, Snake River fish typically have SARs less than 1-2%, hence the continued downward spiral to extinction. Anadromous fish that pass through fewer hydroelectric dams on the Columbia River system have higher SARs and higher levels of survival (Figures 2 and 3). Figure 2. Survival Rates (SARs) for Adult Returns of Anadromous Fish to the Deschutes, John, Day, Yakima and Lower Granite Dam on the Snake River. Fish that pass through more dams have lower survival rates with Snake River fish well below regional recovery goals. Figure 3. Smolt to Adult Return Ratios (SARs) for wild Chinook and Steelhead for the Deschutes, John Day, Yakima and Snake Rivers. Note that Snake River fish fail to meet break even goals. With cumulative impacts of direct and delayed mortality from the hydro system from the Snake River to the Pacific Ocean, It is obvious that salmon and steelhead cannot meet regional 2-6% SAR goals. Like the Snake River wild Coho that went extinct in the mid-1980s, Chinook, sockeye and steelhead are doomed to extinction unless a combination of dam breaching of the 4 lower Snake River dams, and the highest spill levels of 125% Total Dissolved Gas (TDG) at the remaining dams on the Columbia mainstem river are implemented.	These estimates are put in context in the Draft EIS on page 301: "To aid the downstream passage of juvenile salmon and steelhead, the co-lead agencies have worked to improve passage and survival past the dams and through the reservoirs of the CRS. Figure 3-112, shows recent estimates of survival at the eight lower CRS projects with fish passage. The dam survival estimates do not include systemwide or latent effects (see section 3.5.3.1). These estimates were developed [to] show progress towards meeting the individual dam survival goals developed during the 2008 Biological Opinion of 96 percent survival past each dam for yearling Chinook and steelhead, and 93 percent for Snake River sub-yearling fall Chinook." Later in this section (referenced in the quotations above) the analysis discusses system survival rates, as well as latent mortality. The analysis of alternatives presented in-river system survival, which reflects the commenter's "cumulative losses", and Smolt-to-Adult return rates (SARs), for those populations which could be modeled, among other metrics. The per-dam survival metric is both accurate and useful in measuring changes in near field survival at the dams due to structural modifications (e.g. surface passage routes) or operation changes (changes to spill levels or spill patterns). The per-dam survival estimates are multiplicative in nature and the improvements in at-dam survival over the past ten years have been shown to contribute to improvements in total in-river survival of smolts migrating through the CRS especially for steelhead. The focus of this EIS and the analysis presented throughout this EIS in Sections 3.5 and 7.7.4 hinge around total in-river survival, travel time, powerhouse passage rates, and SARs. Based on the EIS analysis of fish in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. With respect to the Preferred Alternative, the CSS model predicts that average SARs will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. These improvements are expected to benefit all of the stocks listed in this comment if latent mortality is reduced through higher spill levels.
4118	8	mggerdes89@gmail.com	N/A	Water Temperatures Another way that the hydro system dams cause impacts to migratory fish is the cumulative effects of high-water temperatures caused by Snake River and Columbia mainstem dams and associated reservoirs. Stagnant reservoirs in combination with increasingly hot temperatures due to climate change are lethal to migrating fish like salmon and steelhead. A water temperature above 680F delays upstream migrating adults, deplete energy reserves, increases respiration, and increases disease ultimately causing direct or delayed mortality. In the hot, dry summer of 2015, a harbinger of future summers in the Pacific Northwest, over 95% of returning Snake River sockeye salmon run died prematurely in the Columbia and Lower Snake rivers, most never making it to the Snake River. A study done by Schultz and Johnson in 2017 used an US Environmental Protection Agency (EPA) model and validated work by the EPA that showed a free-flowing Lower Snake River would have remained cooler than 68F during most of the hot summer of 2015. The analyses by Schultz and Johnson demonstrated that in dammed reaches of the lower Snake River, especially the three downstream reservoirs, water temperature reached 68F in mid to late June and remained near or above 68F until September (Figure 4). Figure 4. Contrast of 2015 summer water temperatures between the dammed Lower Snake River (left) and a modeled, free-flowing Lower Snake River (right). Note temperatures in the free-flow river would have largely remained below 68F through the summer. Essentially, as water moves slowly downstream through the 4 lower Snake River dams and associated reservoirs, each reservoir increases water temperature by about 20F or more. The free-flowing simulation showed no significant and long term rising temperatures and that without the dams, water temperatures in the lower Snake River would warm a relatively minor amount as it flowed to the Columbia River. Despite perilously hot air temperatures and low flows that occurred in 2015, the lower Snake River would have been cool enough for salmon and steelhead if the dams had not been present. While there would have been minor increases in temperatures, they would have been short lived. With the existing 8 dam complex that fish navigate from the Snake River to below Bonneville, Dam, and climate change intensifying the impacts of high temperatures and low flows, Snake River fish are at risk of extinction. High water temperatures above 68F are now common for lengthy periods in July, August, and September. The only way to ensure survival and avoid extinction of Snake River anadromous fish is to have a free-flowing lower Snake River.	The Draft EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives' effects on salmon and steelhead, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Water temperatures under MO3, which includes breaching the four lower Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The models showed minor changes in the Columbia River under this alternative. Regarding climate change, the climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at the required resolution (river-scale vs. global- or regional-scale) at this time. Therefore it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3 and Section 7.8.3 in the Draft EIS). Regarding predicted water temperatures under MO3, as compared to the results documented by Schultz and Johnson (2017) and derived from past EPA analysis, there are a few key differences between these efforts that should be made clear. First, the RBM-10 (TMDL) model predicts a daily average water temperature, while the CE-QUAL W2/HEC-RAS (EIS) model predicts a daily maximum value. The co-lead agencies chose the daily maximum water temperature metric since most water quality standards are based on this metric. Second, the RBM-10 model uses weather data from airport weather stations with the longest records, whereas the co-lead agencies used weather stations with the most spatial coverage and spatial representation (airport and AgriMet weather stations). Lastly, RBM-10 was utilized for a free-flowing scenario. The free-flowing scenario includes the absence of Grand Coulee, Chief Joseph, the 5 mid-Columbia PUD dams, the lower four Columbia River and the lower four Snake River dams. However, this "free-flowing" scenario retains Dworshak Dam as a boundary condition and uses observed flows and temperatures. 2010 channel bathymetry is utilized throughout system. The TMDL assessment focused on quantifying the thermal load of the dams by comparing existing conditions to a free-flowing scenario. The co-lead agencies used HEC-RAS (1-dimensional model) for the MO3 alternative for the lower Snake River; CE-QUAL W2 (2-dimensional model) was used for the other mainstem CRS dams. MO3 includes removing the earthen embankments, abutments and portions of existing structures at the dams to eliminate reservoirs. All other CRS dams remain in place. Dworshak Dam uses modeled flows and temperature. 1934 (pre-dam) channel bathymetry was utilized throughout the lower Snake River; 2010 geometry was used elsewhere in the system. The CRSO EIS assessment focused on predicting water temperature and Total Dissolved Gas conditions under the MO3 alternative, which included a measure for breaching all four lower Snake River dams. Given the differences between the analysis in the Draft EIS and the 2017 study, direct comparisons between the two assessments are not appropriate. Both models have been reviewed extensively by the co-lead agencies and EPA and concluded that both temperature models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As stated in EPA's review letter (#16-0059), EPA agreed with the co-lead agencies that the CE-QUAL W2 and HEC RAS models were appropriate to use in developing the Draft EIS.
4118	9	mggerdes89@gmail.com	N/A	Alternatives The co-lead agencies tout the Flex Spill Agreement in the CRSO-DEIS as the basis for the Preferred Alternative and conclude that small adjustments in spill and other mechanistic fixes in the hydro system will improve survival of anadromous fish while retaining all the perceived benefits of the 4 lower Snake River dams energy, water transport of freight, flood control and irrigation. The Flex Spill Agreement was a process and intended to avoid litigation during the time that the CRSO-DEIS was developed. The Preferred Alternative is a version of the Flex Spill agreement with modifications that benefit power generation revenue and irrigation. There are no improvements for Snake River salmon and steelhead populations included in this alternative. It does not include operations for the long term, and only addresses operations for the last year of the Flex Spill Agreement in 2021. While co-lead agencies make references in the Preferred Alternative to an indeterminate and open-ended adaptive management process, there is no guarantee that the regional 4% average SAR goal will be met. Indeed, the Preferred Alternative includes measures that will cause additional harm to salmon and steelhead populations, such as additional irrigation water withdrawals from the Columbia River of 1.254 million acre-feet. While the Preferred Alternative claims to be a balanced approach, it is obviously a continuation of status quo management which has caused salmon and steelhead to reach the brink of extinction and in some measures, the Preferred Alternative causes additional harm to fish. A careful review of the Flex Spill in 2019 showed that downstream survival, from juvenile fish powerhouse encounters, and delayed water transit time was equal to or worse than the 2018 Biological Opinion (BiOP) spill flows. Essentially higher spill should equate to decreased mortality and higher juvenile survival because fish are passed over the spillways instead of going through the powerhouses. The Flex Spill agreement states that fish passage must be better or at least no worse than what would have occurred under the 2018 court ordered injunctive spill order. However, in 2019 juvenile fish passage through powerhouses was worse than the injunctive spill order and more fish went through powerhouses than would have occurred under the court ordered spill. Spill to the higher 125% TDG level was only provided at 4 of the 8 Columbia/Snake hydroelectric projects. For example, Bonneville, The Dalles, and John Day dams spill were capped at 120% TDG. Further all of the projects reduced spill for 8 of the 24-hour day cycle which decreased fish protection at these projects during those 8 hours of reduced spill. The Columbia/Snake hydropower system cannot meet the alleged purpose of the Flex Spill agreement because spill is a net reduction at the downriver projects. Therefore, Oregon and Washington fish stocks from the John Day, Deschutes and Yakima rivers had increased mortality and decreased survival from increased powerhouse encounters.	The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. In the EIS analysis of effects, the co-lead agencies used high quality data and best science, including models and studies published in peer-reviewed science journals. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The CSS model predicts that average Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. The commenter's suggestion that the flex spill operation is only planned for one year is not an accurate interpretation of the Preferred Alternative. The 2019-2021 Spill Operation Agreement was a short-term agreement that was intended to last until the Record of Decision for the CRSO EIS was signed. However, the fact that it was a short-term agreement did not preclude the co-lead agencies from considering the operation as a measure to include in the EIS. In fact, this operation proposes to provide a high potential benefit to salmon and steelhead through increased spill while avoiding many of the adverse impacts to power generation and reliability associated with Multiple Objective alternative 4 (MO4). This measure also would allow the co-lead agencies to gather important scientific information on the relationship between the CRS and latent mortality. This measure would be managed adaptively, through the established Regional Forum processes, to address unexpected challenges, such as potential delays to adult migration or temporary operations needed to maintain navigation. If no adaptive management needs are identified, the operation would continue until modified by a subsequent biological opinion (BiOp) or National Environmental Policy Act (NEPA) analysis. Regarding the performance of 2019 flex spill, which was planned for a 120% total dissolved gas (TDG) level: one year of in-river data to assess the benefits of flex spill is not adequate because the primary metrics will be SARs, so the co-lead agencies will have to wait for generations of adult returns to assess the effectiveness of the action. The Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas (TDG)-related mortality of juvenile migrants. The framework for the adaptive management process is detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
4118	10	mggerdes89@gmail.com	N/A	The Fish Passage Center sent a memo to the co-lead agencies on January 24, 2020 that plainly showed that the Preferred Alternative is a high risk alternative for Snake River salmon and steelhead . In the lower quartile data range, low SARs and continued population decline (<1% SARs) are predicted to occur a majority of the time and even more expected with warming and drying climate conditions. The Preferred Alternative has no fundamental changes to restore Snake River salmon and steelhead. The ambiguous reference to adaptive management processes continues the status quo and fails to restore Snake River anadromous fish. This CRSO-DEIS fails to meet the purpose and need to evaluate how to insure that the prospective management of the System is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of designated critical habitat (CRSO-DEIS, Executive Summary, page 16). The only option for recovery and avoiding extinction of Snake River salmon and steelhead is to breach the 4 lower Snake River dams (Alternative MO3) and spill to the 125% tailrace TDG gas cap (Alternative MO4) at remaining projects, 24 hours per day. Until the dams are breached, spilling to 125% at all dams is an interim measure to keep these fish on life support. The combined MO3 and MO4 show the greatest improvements and the only path to successfully restore anadromous fish from the Snake River. These combined alternatives have the highest probability of meeting the 4% average SAR regional goal. Even the lower end of the predicted SAR range for MO3 was also above 1% for both Chinook and steelhead. The remaining alternatives (No Action, MO1, MO2, and the Preferred Alternative) fail to meet the regional 4% SAR goal, and the lower end of the predicted SAR ranges are well below 1%, indicating a high risk of extinction.	The co-lead agencies contracted with the Fish Passage Center (FPC) to produce the CSS modeling results presented in the Draft EIS. Any additional modeling that was not presented in the Draft EIS is not part of the CRSO EIS and was not developed by the co-lead and cooperating agencies. The co-lead agencies used the high quality data in the analysis of the CRSO EIS. This analysis is documented in Chapter 3 of the Draft EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing SARs from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict different outcomes, depending on assumptions used for decreased latent mortality. To address this uncertainty, the Preferred Alternative will be implemented using a robust monitoring plan. In their 2017 report FPC, analyzed increased spill over BiOp spill and found that without dam breach, a 2.0-2.5 fold increased in abundance for Snake River salmon could be achieved with spill to the 120% and 125% gas cap. The 4% SARs target referenced in this comment refers to the Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. However, the Councils broad sense recovery goals are beyond the scope of this EIS which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. With respect to the request to consider a combination of MO3, which includes a measure to breach the four lower Snake River dams, and Multiple Objective alternative 4 (MO4), which includes a measure to spill at the lower Columbia River dams to 125% total dissolved gas (TDG) levels, the co-lead agencies disagree that this is a reasonable alternative given public safety issues that would be expected from combining these two measures. MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these Multiple Objective alternatives (MOs) were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire United States by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
4130	1	dh@oregonwild.org	Oregon Wild	This project includes a goal to minimize GHG emissions. This is a laudable goal- one that should be embraced in the land management plans of the USDA Forest Service and USDI Bureau of Land Management. However, in the context of river management this goal should be broadened to embrace a more holistic climate strategy. Direct emissions of GHG is only part of the picture. The DEIS needs to recognize that: Replacement power can be obtained from renewable sources, not natural gas. This is increasingly true over time as investment in renewable energy continues and increases; Reservoirs of water tend to increase GHG emissions (including notably methane) compared to water moving more swiftly to the ocean. Prairie YT, Alm J, Beaulieu J, et al. Greenhouse Gas Emissions from Freshwater Reservoirs: What Does the Atmosphere See?. Ecosystems. 2018;21(5):10581071. doi:10.1007/s10021-017-0198-9. https://www.ncbi.nlm.nih.gov/pmc/articles/PMC6309167/pdf/nihms-1511344.pdf; Exposing and restoring the lands currently inundated by the lower Snake reservoirs will allow terrestrial ecosystems to increase carbon sequestration; Conservation and recovery of salmon populations will hypercharge the conveyor belt of nutrients from the ocean to the continent. Those salmon-derived nutrients will enhance ecosystem carbon uptake in riparian areas and a variety of carbon-rich terrestrial ecosystems; A free-flowing Snake River with a functioning floodplain will support ecosystem services that are more resilient to climate extremes;	The co-lead agencies appreciate this comment characterizing the complexity associated with system level analyses of greenhouse gas (GHG) emissions and climate resiliency effects. Sections 3.8 and 7.7.10 of the Draft EIS describes these multiple different ways that the CRSO EIS alternatives may affect sources and sinks of GHG emissions. Consistent with the considerations described in this comment, the analysis considers a scenario in which renewable resources are developed or acquired to replace reductions in hydropower (as opposed to natural gas), the potential for methane emissions reductions associated with breaching the lower Snake River dams (Appendix G and Section 3.8.3.5), and the potential effects of land use and land cover changes on landscape carbon sequestration capacity. Recognizing the importance of considering emissions and climate effects, the EIS considers these beneficial and adverse effects of the multiple objective alternatives within the broader context of tradeoffs, for example including the regional cost of power and water supply and costs to farmers of shipping commodities.
4156	1	staylor@cowlitzpud.org	Cowlitz PUD	Cowlitz PUD purchases over 90 percent of its wholesale power from BPA, the vast majority of which is generated by the Federal Columbia River Power System (FCRPS). The value of these purchases is equivalent to nearly 7% of BPAs total annual operating costs. Two-thirds (66%) of the PUDs electric load is derived from trade-exposed pulp and paper manufacturing industries, and the utilitys residential customer base is challenged with a disproportionate rate of poverty (16.9% vs. 11.8% U.S average). Substantive increases in utility rates have direct negative impacts on Cowlitz PUDs low-income families and could lead to cascading detrimental effects for the community in the event large industrial customers can no longer operate economically within our service area.	The comment that increases in utility costs can adversely affect vulnerable groups is consistent with discussions in the EIS. The Environmental Justice analysis in Sections 3.18.3 and 7.7.20 of the Draft EIS provide further detail on potential disproportionate effects including to tribal, low-income, and minority populations. The EIS also discusses the fact that Bonneville customers, such as cooperatives mentioned by the commenter, may be more directly affected by rate pressures than other regional utilities that do not purchase power directly from Bonneville (see Section 3.7.3.5 Summary of Effects).
4156	2	staylor@cowlitzpud.org	Cowlitz PUD	Preferred Alternative Concerns Reduction in Carbon-free Generating Capacity Implementation of the increased spring spill operations up to the proposed 125% total dissolved gas cap is projected to result in the loss of 160 aMW of clean, firm and flexible hydropower generation. The PAs actions project upward BPA rate pressure of 2.7%, but possibly as low as 0.4%, which, on its face, appear to be moderately impactful. However, this additional rate pressure is of great concern when placed in context with the escalating costs of Tier 1 power since the 2010-2011 rate periodincreases primarily attributed to the funding of fish and wildlife mitigation programs. Rate Period Tier 1 Rate Increase 2012-13 8.2% 2014-15 8.6% 2016-17 7.1% 2018-19 5.4% 2020-21 2.0%* *effective increase due to power reserve surcharge	The EIS recognizes the concern voiced in the comment regarding increasing power rates under the Preferred Alternative. The power rate increase quoted in the comment is consistent with the findings of the EIS; however, it is important to note these estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement, and therefore, already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control. See Draft EIS Section 3.7.3.1, page 3-817.
4156	3	staylor@cowlitzpud.org	Cowlitz PUD	Cowlitz PUD is also concerned these rate impacts are extremely optimistic and do not adequately account for the evolving energy landscape in the West as it is influenced by carbon-free policy initiatives and the early retirement of 2,505 MWs of coal-fired firm generation. The retirement of thermal resources is leading the region toward unacceptable levels of capacity deficiencies (from 6.5% to 24% loss of load probability), making this proposed reduction in FCRPS generation a move in the wrong direction as the electric sector seeks viable solutions to address the resource adequacy deficit. The PUD suggests the final EIS establish a new base case within the Power Generation and Transmission Analysis which incorporates the expected coal-fired generation loss and costs of replacing the lost hydropower capability with new carbon-free resources.	The commenter's statement that potential additional coal power retirements would decrease power reliability in the region is consistent with the findings in the EIS. As noted in the comment, existing coal projects were presumed to be online when developing the No Action Alternative. Since development of the Draft EIS, additional coal retirements have been announced. To address this concern, the EIS considered various sensitivity analyses as well as examining two potential coal retirement scenarios. See Draft EIS, Section 3.7.3.1, Availability of Coal Resources, pages 3-841-842; and Section 3.7.3.2, Table 3-123. The EIS acknowledges that assumptions regarding coal capacity have changed since the base case was developed in 2017, and the EIS presents base case analysis first before discussions of information resulting from additional sensitivities and potential cost pressures.
4156	4	staylor@cowlitzpud.org	Cowlitz PUD	Impacts to Large Industrial Facilities Access to an adequate, reliable, and affordable supply of power is integral to the viability of Cowlitz Countys large industrial base which, as stated above, comprises two-thirds of Cowlitz PUDs annual load. The manufacturing processes the facilities employ are highly sensitive to even minor system disturbances. Unplanned outages or rolling blackouts resulting from resource and transmission deficiencies have consequential impacts on these energy-intensive entities, which provide and support thousands of family-wage jobs in the local community. The pancaking of multiple cost layers associated with carbon-free power acquisition, regulation of carbon emissions, and salmonid preservation coupled with real concerns over the future reliable delivery of electricity has a significant detrimental effect on the competitive position of energy-intensive industries within our service area. While we recognize the PAs impacts are only one component of the broader picture, controlling BPA rates while maintaining system reliability is paramount to sustaining the industrial base and preserving local jobs.	The Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control. See Draft EIS Section 3.7.3.1, page 3-817. The analysis of the Preferred Alternative did not indicate an increase in the risk of power shortages compared to the No Action Alternative, as the decrease in generation is primarily in the spring when the system is least-likely to have a deficit.
4156	5	staylor@cowlitzpud.org	Cowlitz PUD	Biological Uncertainty of Increased Spill Cowlitz PUD is concerned about the biological uncertainty that the PA may create. The increased spill operations are intended to be a more effective passage method than turbine or bypass passage to avoid direct injury, therefore benefitting juvenile salmonid outmigration. However, the Action Agencies must question assumptions and predictions about the benefits of spill by monitoring the increased spill levels for unintended consequences. One consequence of increased spill is the uncharted increase to 125% of total dissolved gas standards and substantive impacts it will have on resident fish, other river organisms, and salmonids through Gas Bubble Trauma. Increased spill can also delay adult migration, harming the very salmonids the operations are intended to assist, even though the full effects will not be realized for years . Cowlitz PUD encourages the Action Agencies to include clear authorization language within the final EIS that allows for adaptive management should the high spill levels be shown, on a large scale, to be detrimental to either adult or juvenile resident or anadromous fish.	The commenter is correct regarding the uncertainty of effects on the Preferred Alternative on salmon and steelhead. Total dissolved gas (TDG) levels are regulated under the Federal Clean Water Act, and administered by the States. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment, Oregon issued a 5-year "standard modification" and Washington issued a permanent rule change, approved by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects; and therefore, monitoring was required by the states and EPA to ensure that any negative effects are detected and allow for adaptive management. The Preferred Alternative will require a robust monitoring plan to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. As discussed in the EIS, the CSS assumptions and model structure predicted significant increases in average Smolt-to-Adult return rates (SARs) and therefore abundance over time. These increases were based on a predicted decrease in latent mortality rates. Neither the National Marine Fisheries Service (NMFS) COMPASS or Lifecycle models predict a decrease in latent mortality, and therefore the NMFS models predict a decrease in SARs and abundance of Snake River populations due to reductions in the proportions of Snake River salmon and steelhead that are transported. As also noted by the commenter, the effect of TDG levels up to 125% saturation in migrating populations is uncertain. The effectiveness of the spill program would be monitored and effects from other sources such as harvest, ocean mortality, and straying will also be accounted for to the extent possible.
4156	6	staylor@cowlitzpud.org	Cowlitz PUD	Predation Management Avian and pinniped predation are the largest individual contributors to endangered and threatened salmonid mortality, therefore Cowlitz PUD would like to see a stronger emphasis placed in the final EIS on predation management to improve salmon populations. Avian predation disruption measures currently in place at John Day Dam is a notable example of predation management that provides a cost-effective and measurable positive impact to fish population. However, Cowlitz PUD believes there are significantly more opportunities for the Region to address this critical issue.	The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. As the commenter notes, the Preferred Alternative also includes the Predator Disruption Operations measure in the John Day reservoir to further reduce avian predation on migrating juvenile fish.
4156	7	staylor@cowlitzpud.org	Cowlitz PUD	Ocean Conditions and Over-harvesting Dam survival rates are just one piece of a larger puzzle that includes in-river smolt predation, water temperature, ocean conditions, and adult salmonid predation/harvest rates, among other factors. Studies have found that the oceans absorb as much as 30 percent of the climates excess carbon and 90 percent of its excess heat . This absorption leads to warmer water temperatures and higher levels of acidity as well as lower levels of oxygen. NOAA Fisheries researcher Lisa Crosier recently stated that scientists worldwide have been documenting almost synchronous declines in salmon populations due to climate change . These results and conclusions underscore the fact that we must address climate change if we hope to restore healthy salmon populations. A 2016 report issued by the Alaska Department of Fish and Game identified that Chinook salmon from	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those the commenter mentions. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service (NMFS) website at: https://www.nwfsc.noaa.gov/research/index.cfm. The co-lead agencies also agree that climate change is a concern. However, the climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at the required resolution (river-scale vs global- or regional-scale) at this time. Therefore it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Sections 4.2.3 and Section 7.8).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Washington, Oregon and California made up 54 percent of the Chinook salmon that were intercepted in commercial troll fisheries and an estimated 48 percent of sport harvest in Alaska. Interior Columbia River Basin fall Chinook stocks accounted for 39 percent of the total troll harvest and 25 percent of the sport harvest in 2016. These harvest rates should be reduced to return more fish to the Columbia River Basin.	Finally, while harvest rates certainly have an effect on salmon populations, the co-lead agencies did not do an in depth analysis of those effects in the Draft EIS. NMFS conducted a complete analysis of harvest in a recent EIS. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and.
4156	8	staylor@cowlitzpud.org	Cowlitz PUD	Equitably Sharing Environmental Mitigation Costs Cowlitz PUD is committed to mitigating the impacts of FCRPS operations, but public power customers should not solely bear incremental fish mitigation costs that provide broader social and environmental benefits. Fish and wildlife costs comprise roughly 25 percent of BPAs power bill to Cowlitz PUD, and the additional cost responsibilities resulting from the PAs implementation should be offset or reallocated to accurately reflect the benefits that the FCRPS brings to the entire Region.	The financial responsibility for fish mitigation is not solely allocated to Bonneville's power ratepayers as the comment suggests. Fish mitigation costs are assigned to each authorized project purpose based on each purposes overall share of project costs, as determined by the cost allocation, by recovering those costs through power rates. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Congress also granted Bonneville discretion to fund the power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992, in some situations, including the Columbia River Fish Mitigation program. (Energy Policy Act of 1992, Pub. L. No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)). Bonneville generally does not, however, directly pay for the capital costs of fish mitigation structures; instead, it reimburses the U.S. Treasury for the power share of appropriations used to construct the structure. Additionally, as described in Section 3.19 of the EIS and Appendix Q, funding to operate the system comes through multiple mechanisms, including Federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. For joint related costs, including funding for fish and wildlife mitigation actions, the Corps and Reclamation receive annual congressional appropriations to fund most, if not all, capital investments. Bonneville reimburses the U.S. Treasury for the power share of these appropriations. Once the investment is in place, Bonneville will typically direct fund the power share of the operations and maintenance costs associated with the facility. In addition to congressional appropriations for fish and wildlife and costs directly funded to Corps and Reclamation by Bonneville, the Bonneville Fish and Wildlife Program (which is separate and distinct from direct funding described above) funds hundreds of projects each year to mitigate the impacts of the Federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the Federal Columbia River Power System (FCRPS). Bonneville uses its authority under 16 U.S.C. 839b(h)(10)(A), to make expenditures to implement its Fish and Wildlife Program. These expenditures provide system-wide funding for actions that also mitigate for the non-power purposes of the CRS, so Bonneville recoups the non-power share of those expenditures from the U.S. Treasury as credit, as required under 16 U.S.C. 839b(h)(10)(C). Bonneville's Fish and Wildlife Program expenditures incurred mitigating the CRS operations identified in the Final EIS and adopted in Bonneville's Mitigation Action Plan would continue to be allocated and borne as provided by existing laws governing the FCRPS and the long-standing accounting procedures used to implement them. As described in Chapter 7 of the EIS, funding decisions for Bonneville's Fish and Wildlife Program are not being made as part of the CRSO EIS process. Future budget adjustments would be made in coordination with the regional entities that help Bonneville implement its Fish and Wildlife Program. The statement that roughly a quarter of costs from Bonneville's power rates are due to fish and wildlife spending is consistent with information provided in the EIS.
4156	9	staylor@cowlitzpud.org	Cowlitz PUD	Recognizing Region-wide Clean Energy Benefits A recent study published in the Proceedings of the National Academy of Sciences found that the Pacific Northwest Region produced and used the cleanest energy in the nation due primarily to BPAs renewable hydropower system. Washington States newly-adopted Clean Energy Transformation Act requires electric utilities to serve its customers with 100 percent carbon-free resources by 2045 and to achieve carbon neutrality by 2030. These standards cannot be feasibly met without the full capacity of the FCRPS to flexibly integrate intermittent wind and solar renewable generation onto the grid. The value derived from the FCRPS generating attributes toward achieving clean energy policy goals must be properly considered and accounted for, and the full costs of the system equitably allocated to all beneficiaries across the Region.	The information provided in the comment regarding the importance of hydropower for regional greenhouse gas emissions goals, and the integration of variable renewables is consistent with the findings of the EIS.
4162	1	Christopher Daniel	Advisory Council on Historic Preservation	On April 29, 2019, the Advisory Council on Historic Preservation (ACHP) received a letter jointly signed by the U.S. Army Corps of Engineers (Corps), the Bonneville Power Administration, and the Bureau of Reclamation, the Co-Lead Agencies (CLA) for the Federal Columbia River Power System (FCRPS) System-wide Programmatic Agreement (SWPA) for the Columbia River System Operations (CRSO). This letter informed consulting parties of the CLAs intent to utilize the SWPA to fulfill the agencys obligations under Section 106 of the National Historic Preservation Act (NHPA) for modifications in the operation, configuration, and maintenance of the 14 Federal Projects in the Columbia River System covered by the new CRSO Environmental Impact Statement (EIS). This new EIS will present a range of alternatives for long-term system operations and evaluate the potential environmental and socioeconomic impacts on flood risk management, irrigation, power generation, navigation, fish and wildlife conservation, cultural resources, water quality and recreation. The CLAs are required to develop this EIS in response to new information and changed conditions in the Columbia River Basin as well the Opinion and Order issued by the U.S. District Court for the District of Oregon related to endangered or threatened species. The CLAs have indicated they intend to conclude this review by September 2020. The CLAs also 2 intend to invite nine additional consulting parties to be signatory or concurring parties using the terms of the SWPA. The ACHP acknowledges that the use of the SWPA to address effects to historic properties from potential changes in the operations and management of FCRPS and to identify additional consulting parties appears appropriate; however, its provisions do not appear adequate to address the dam breaching alternative and related impacts. As such, the ACHP would urge the CLAs to carry out a Section 106 review for this action in one of two ways set out in the ACHPs regulations at 36 CFR 800.8(c) or 800.14(b). The ACHP offers the following recommendations and comments concerning several critical items. We appreciate the CLAs consideration of these comments and recommendations as it continues consultation on this matter.	The co-lead agencies appreciate the public comment submitted by the Advisory Council on Historic Preservation (ACHP) and acknowledge this comment was previously submitted to the co-lead agencies as part of a single letter dated June 19, 2019, during the ongoing Section 106 of the National Historic Preservation Act consultation process as a partial fulfillment for the CRSO EIS National Environmental Policy Act (NEPA) process. The co-lead agencies responded in writing to the ACHP on November 27, 2019. The co-lead agencies also acknowledged and appreciated the ACHP's support for using Stipulation XVI.F of the Federal Columbia River Power System (FCRPS) Systemwide Programmatic Agreement (SWPA) to add additional consulting parties who wish to be signatories to the SWPA and participate in the ongoing FCRPS Cultural Resource Program. The co-lead agencies further acknowledged the ACHP supports the use of the SWPA for compliance with Section 106 regarding the undertaking resulting from the CRSO EIS, with exception of the undertaking that includes dam breaching. However, the co-lead agencies believe additional Section 106 compliance cannot be completed at this time for an alternative that includes analyzing dam breach for the four lower Snake River dams (included in Multiple Objective Alternative 3) in the CRSO EIS. The reasons Section 106 cannot be completed at this time for MO3, are the requirement of the implementing regulations (36 C.F.R. 800.2(a)) "that an agency official with jurisdiction over an undertaking takes legal and financial responsibility for an undertaking .... The agency official has approval authority for the undertaking and can commit the Federal agency to take appropriate action for a specific undertaking as a result of section 106 compliance." Although an alternative that analyzes dam breach of the four lower Snake River dams could be selected as the alternative recommended by the co-lead agencies in their respective decisions, all the co-lead agency officials lack the approval authority and jurisdiction necessary to authorize dam breach of the four lower Snake River dams without first following the path described in the Declarations submitted to the United States District Court for the District of Oregon and summarized on the CRSO EIS website: https://www.nwd.usace.army.mil/Media/Fact-Sheets/Fact-Sheet-Article-View/Article/1708265/proiect-authorities-overview/ Starting a separate Section 106 process now, especially the drafting of a new programmatic agreement or utilizing the National Environmental Policy Act (NEPA) substitution process as suggested by the ACHP, would not enhance the evaluation of effects to historic properties in any meaningful way. A new programmatic agreement would not provide additional information about impacts to historic properties. Instead, it would simply lay out a process that the co-lead agencies have already committed to in the SWPA. In the same manner, the NEPA substitution process would rely on the CRSO EIS, and, therefore, that information would be the same regardless of whether the co-lead agencies explicitly used substitution or not. Furthermore, the co-lead agencies respectfully disagree with the ACHP's statement that selection of the alternative that includes dam breach of the four lower Snake River dams would conflict with the timing requirement of 36 C.F.R. 800.1(c) or restrict the ability of the co-lead agencies to identify measures to avoid, minimize, or mitigate adverse effects to historic properties. If the alternative that includes breaching the four lower Snake River dams were to become the selected alternative, the USACE would use the CRSO EIS, the subsequent recommendation of an alternative that includes dam breach in the Record of Decision (ROD), and the other necessary actions outlined in the Declarations to seek congressional authorization and appropriations. If Congress were to authorize dam breach of the four lower Snake River dams and appropriate funds, the designated agency or agencies would then embark on a NEPA process to identify a range of alternatives to avoid, minimize, or mitigate adverse effects, and conduct other necessary environmental compliance, prior to initiating and completing dam breach. Only when this subsequent NEPA process commences would dam breach be an undertaking with sufficient clarity to identify potential effects to historic properties and appropriate alternatives to avoid, minimize or mitigate those effects. The co-lead agencies appreciate the comments, recommendations, advice, and support from the ACHP as we move forward with Section 106 compliance and the continued implementation of the SWPA.
4162	2	Christopher Daniel	Advisory Council on Historic Preservation	Section 106 Compliance for Changes to CRSO As noted above, the ACHP agrees with the CLAs proposal to use the SWPA to address its ongoing Section 106 compliance responsibilities for any changes in the operation, configuration, and maintenance of the dams that might occur under the CRSO EIS decision. It appears, based on the information provided, that these changes would fall within the existing scope of the undertaking as described in the SWPA. We recommend the CLAs provide to the consulting parties an explanation of the spectrum of activities that might result from changes to CRSO and more specifically how the SWPAs provisions would be sufficient to address these changes and satisfy its consultation requirements. However, the ACHP is concerned that the SWPA, which was developed to address on-going maintenance and operations, is not sufficient to resolve the types of effects to historic properties that may result from the breaching of the four lower Snake River dams and believes that additional consultation is necessary to develop measures to resolve such effects, should the CLAs determine it appropriate to select this alternative directing them to seek congressional authorization for breaching. At this time, the full scope of the undertaking is unclear, but it is reasonable to assume that a decision to pursue breaching any or all of the four dams would affect historic properties. As stated in the April 29, 2019 letter to the ACHP, the Section 106 process will be carried out pursuant to the SWPA for all other alternatives with the exception of breaching. The ACHP agrees with this assertion, but disagrees that no additional Section 106 review would be required for the breaching alternative at this time. Previous documentation, such as the 2017 Ponganis Declaration, indicates that the CLAs, and specifically the Corps, would undertake additional environmental analysis, including Section 106 consultation, if the breaching alternative were to be selected and congressional authority granted for a breaching. It is our understanding that it is likely the development of the breaching alternative in the EIS would result in a specific proposal for action to be carried out by one of the CLAs and submitted for congressional authorization. Therefore, it follows that, should this course of action be selected and such authorization sought, alternatives to avoid, minimize, or mitigate adverse effects to historic properties would already have been restricted, if not eliminated, and thus, such decision making would conflict with the timing requirement stated in 36 CFR 800.1(c). The ACHP recognizes that conducting a Section 106 review for the breaching alternative would be challenging at this time based on the need for continued coordination and because effects to historic properties could not be fully determined prior to pursuing congressional authorization should this alternative be selected. In light of this situation, the ACHP recommends either, 1) the CLAs develop and execute a programmatic agreement pursuant to 36 CFR 800.14(b)(3) with identified consulting parties that would recognize the potential for adverse effects from any breaching, and would set forth further consultation, identification, and resolution efforts after such authority was granted; or 2) utilize the procedures and documentation required for the preparation of an EIS/Record of Decision to comply with Section 106, pursuant to 36 CFR 800.8(c). Both of these approaches allow the CLAs to recognize the need for further consultation if breaching is selected and authority granted; in the latter option, 3 compliance with Section 106 could be documented in the ROD without the need for a separate PA. Both of these solutions would also require the CLAs to consult on the potential effects of the breaching alternative, acknowledging that discussion would be limited to the information and documentation available at the time, and focused on establishing a process for continued consultation moving forward. Executing a separate PA or substituting the process and documentation required for preparation of the EIS for the Section 106 review, concluding with binding commitments in the ROD to resolve adverse effects, would assist in satisfying the CLAs Section 106 responsibility for this proposed action. If initiated soon, the development of measures for either of the above approaches could be accomplished quickly and without much difficulty. Additionally, the ACHP would commit to assisting the CLAs in this consultation as we recognize the timing constraints placed on the CRSO EIS.	The co-lead agencies appreciate the public comment submitted by the Advisory Council on Historic Preservation (ACHP) and acknowledge this comment was previously submitted to the co-lead agencies as part of a single letter dated June 19, 2019, during the ongoing Section 106 of the National Historic Preservation Act consultation process as a partial fulfillment for the CRSO EIS National Environmental Policy Act (NEPA) process. The co-lead agencies responded in writing to the ACHP on November 27, 2019. The co-lead agencies also acknowledged and appreciated the ACHP's support for using Stipulation XVI.F of the Federal Columbia River Power System (FCRPS) Systemwide Programmatic Agreement (SWPA) to add additional consulting parties who wish to be signatories to the SWPA and participate in the ongoing FCRPS Cultural Resource Program. The co-lead agencies further acknowledged the ACHP supports the use of the SWPA for compliance with Section 106 regarding the undertaking resulting from the CRSO EIS, with exception of the undertaking that includes dam breaching. However, the co-lead agencies believe additional Section 106 compliance cannot be completed at this time for an alternative that includes analyzing dam breach for the four lower Snake River dams (included in Multiple Objective Alternative 3) in the CRSO EIS. The reasons Section 106 cannot be completed at this time for MO3, are the requirement of the implementing regulations (36 C.F.R. 800.2(a)) "that an agency official with jurisdiction over an undertaking takes legal and financial responsibility for an undertaking .... The agency official has approval authority for the undertaking and can commit the Federal agency to take appropriate action for a specific undertaking as a result of section 106 compliance." Although an alternative that analyzes dam breach of the four lower Snake River dams could be selected as the alternative recommended by the co-lead agencies in their respective decisions, all the co-lead agency officials lack the approval authority and jurisdiction necessary to authorize dam breach of the four lower Snake River dams without first following the path described in the Declarations submitted to the United States District Court for the District of Oregon and summarized on the CRSO EIS website: https://www.nwd.usace.army.mil/Media/Fact-Sheets/Fact-Sheet-Article-View/Article/1708265/proiect-authorities-overview/ Starting a separate Section 106 process now, especially the drafting of a new programmatic agreement or utilizing the National Environmental Policy Act (NEPA) substitution process as suggested by the ACHP, would not enhance the evaluation of effects to historic properties in any meaningful way. A new programmatic agreement would not provide additional information about impacts to historic properties. Instead, it would simply lay out a process that the co-lead agencies have already committed to in the SWPA. In the same manner, the NEPA substitution process would rely on the CRSO EIS, and, therefore, that information would be the same regardless of whether the co-lead agencies explicitly used substitution or not. Furthermore, the co-lead agencies respectfully disagree with the ACHP's statement that selection of the alternative that includes dam breach of the four lower Snake River dams would conflict with the timing requirement of 36 C.F.R. 800.1(c) or restrict the ability of the co-lead agencies to identify measures to avoid, minimize, or mitigate adverse effects to historic properties. If the alternative that includes breaching the four lower Snake River dams were to become the selected alternative, the USACE would use the CRSO EIS, the subsequent recommendation of an alternative that includes dam breach in the Record of Decision (ROD), and the other necessary actions outlined in the Declarations to seek congressional authorization and appropriations. If Congress were to authorize dam breach of the four lower Snake River dams and appropriate funds, the designated agency or agencies would then embark on a NEPA process to identify a range of alternatives to avoid, minimize, or mitigate adverse effects, and conduct other necessary environmental compliance, prior to initiating and completing dam breach. Only when this subsequent NEPA process commences would dam breach be an undertaking with sufficient clarity to identify potential effects to historic properties and appropriate alternatives to avoid, minimize or mitigate those effects. The co-lead agencies appreciate the comments, recommendations, advice, and support from the ACHP as we move forward with Section 106 compliance and the continued implementation of the SWPA.
4162	3	Christopher Daniel	Advisory Council on Historic Preservation	Newly Identified Consulting Parties The ACHP is supportive of the CLAs approach to utilize Stipulation XVI.F of the SWPA to add additional consulting parties as this mechanism provides an avenue for new consulting parties to engage in consultation and participate in the cooperating groups that assist in guiding reviews under the SWPA. We request the CLAs keep the existing consulting parties informed as to the responses received to this request and that the SWPA document the outcomes via the annual report and share copies of any new signature sheets. In the future, if the SWPA were to be	The co-lead agencies appreciate the public comment submitted by the Advisory Council on Historic Preservation (ACHP) and acknowledge this comment was previously submitted to the co-lead agencies as part of a single letter dated June 19, 2019, during the ongoing Section 106 of the National Historic Preservation Act consultation process as a partial fulfillment for the CRSO EIS National Environmental Policy Act (NEPA) process. The co-lead agencies responded in writing to the ACHP on November 27, 2019, and thanked them for their letter. The co-lead agencies also acknowledged and appreciated the ACHP's support for using Stipulation XVI.F of the Federal Columbia River Power System (FCRPS) Systemwide Programmatic Agreement (SWPA) to add additional consulting parties who wish to be signatories to the SWPA and participate in the ongoing FCRPS Cultural Resource Program. The co-lead agencies will keep existing consulting parties informed of responses from

				amended, the ACHP recommends assessing this section to adjust the current language to make it more precise on how to document the involvement of additional consulting parties.	new consulting parties, will continue documentation in our FCRPS annual report, and share copies of any new signatory sheets to the SWPA. The co-lead agencies further appreciate the ACHPs recommendation that, if the SWPA were to be amended, the co-lead agencies should reassess the section documenting the involvement of additional consulting parties.
4192	1	dlwhitcomb@aol.com	N/A	I read much removing dams to mitigate salmon decline on the Snake/Columbia River system but nothing about the effect of contaminant pollution and the viability of salmon on the many estuaries in the Puget Sound area. When are you going to recognize this impact. The following two studies clearly describe the significant metabolic effects of the contaminants being continually discharged into estuaries from the communities in the Puget Sound area on the salmon smolt. In addition to a know effect on the salmon, these contaminants include birth control drugs that could will concentrate in the fish fats and be consumed by the ORCA's--birth controll will effect the reproduction. Salmon recovery needs to address all the issues and not just the dams, which salmon mortality is being continually reduced by improvements in the turbines and other equipment. Contaminants of emerging concern in a large temperate estuary* James P. Meador a, b, *, Andrew Yeh b, 1, Graham Young c, d, 2, Evan P. Gallagher b, 1 a Ecotoxicology and Environmental Fish Health Program, Northwest Fisheries Science Center, NOAA Fisheries, Seattle, WA, 98112, USA b Department of Environmental and Occupational Health Sciences, University of Washington, Seattle, WA, USA c School of Aquatic and Fisheries Sciences, University of Washington, Seattle, WA, USA d Center for Reproductive Biology, Washington State University, Pullman, WA, USA Received 19 November 2015 Received in revised form 26 January 2016 Accepted 29 January 2016 Adverse metabolic effects in fish exposed to contaminants of emerging concern in the field and laboratory*,** James P. Meador a, b, *, Andrew Yeh b, 1, Evan P. Gallagher b, 1 a Environmental and Fisheries Sciences Division, Northwest Fisheries Science Center, National Marine Fisheries Service, National Oceanic and Atmospheric Administration, 2725 Montlake Blvd. East, Seattle, WA 98112, USA b Department of Environmental and Occupational Health Sciences, School of Public Health, University of Washington, Seattle, WA 98105, USA a r t i c l e i n f o Article history: Received 10 November 2017 Received in revised form 18 January 2018 Accepted 4 February 2018	The co-lead agencies agree that there are many effects to salmon and steelhead populations outside the operations of the dams. As these effects would be outside the Columbia River Basin, minimally affect any resource in the basin, and the same for all alternatives analyzed, they are minimally discussed in EIS where appropriate. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service website at: https://www.nwfsc.noaa.gov/research/index.cfm
4223	1	Elizabeth McKeag	N/A	As far as the analysis being unacceptable, I will just reiterate the previous comments about how crazy it is that the economic implications of the sport fishing industry were not evaluated in this EIS, especially considering they were evaluated in previous EISs. And this information is publicly available through several sources, including the Idaho Fish and Game Department. And my understanding was that you were potentially given this information during the cooperating agency portion of the analysis. So anything moving forward must include that consideration, especially since barging, transportation, energy, everything else had a quantitative analysis, while for some reason fishing was only allowed a qualitative analysis.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The recreation analysis for the EIS considered the broad range of recreational activities supported by the region, including recreational fishing. While the analysis described any potential impacts to recreational fishing visitation, the EIS did not estimate these impacts separately from the overall impacts to recreation, or estimate changes in fishing visitation related to changes in fish abundance. The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which are described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. For Multiple Objective alternative 1 (MO1), Multiple Objective alternative 2 (MO2), and Multiple Objective alternative 4 (MO4), and the Preferred Alternative (PA), the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the PA and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
4224	1	jmichael.photo@gmail.com	N/A	And I just want to give a reminder that research at Washington State University in recent years has shown that these slack water reservoirs do produce significant amounts of methane. So it's not entirely honest to call the energy that these dams produce carbon-free.	The EIS evaluates the research pertaining to methane emissions from hydropower reservoirs. Appendix G, Chapter 5 of the EIS details the assessment of reservoir methane emissions from the CRS projects. The findings are summarized in Section 3.8. This assessment finds that reservoir characteristics and management substantially influence methane emissions. A 2016 study developed by the Corps' Walla Walla District concluded that for the relatively clean reservoirs of the Federal Columbia River Power System, which include the lower Snake River dams, conditions for low dissolved oxygen concentrations are not prevalent; thus methane gas is generally not an issue. Additionally, in 2017, the Northwest Power and Conservation Council found that data on these sites were insufficient to estimate the reservoir methane emissions specifically for the Columbia River hydrosystem, but that methane emissions at high levels are not likely due to the lower organic and nutrient loads to the system, and higher dissolved oxygen content. The EIS describes that emerging technologies will allow for better measuring and understanding the effects of reservoir methane emissions from CRS projects, including the four lower Snake River dams.
4225	1	Sarah Highfield	N/A	Since 1978, Whitman County has produced more wheat than any other county, not just in the state, but across the nation. The vitality of our agricultural communities and the continued operation of the dams cannot be disentangled, as dam breaching proponents would argue. Whitman County wheat growers owe their competitive edge to barging. About 80 to 90 percent of the grain grown in our region ships to oversea markets. Growers can compete internationally because of their high product quality and low price point, made possible by barging, the least-expensive means of transport. As the Draft EIS states, breaching the dams would eliminate this valuable shipping method, swelling transportation and associated product costs, crowding our roads, and compounding carbon emissions. This, coupled with the $500 million loss in irrigation, places many family farms at great risk. The Draft EIS captures some of this economic and societal impact, but we believe it is understated still. A study commissioned by the Pacific Northwest Waterways Association assessed the impacts that would result if barging on the Snake River is lost. The study found that if (inaudible), more than 1,100 farms could be at risk of bankruptcy. With wheat prices already down near the break-even point, the study calculates that the federal government would need to increase annual direct payments to farmers, that up to $38.8 million to maintain (inaudible) level. Among the farmers who escape bankruptcy, how many would rather retire than face steep losses?How many future generations would forfeit a rich farming tradition as their family operations go under? According to the 2017 Census of Agriculture, the average age of a farmer in the United States is 57.5, and 96 percent of farms and ranches are family-owned. Family farms, the foundation of our country, would crumble under an extreme decision to breach the lower Snake River dams —- consideration should be elaborated in the report as well. Nearly one in five people living in the 10-county area most impacted by a dam-breaching alternative, including Whitman County, are at or below the federal poverty level.	The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in section 3.10.3.5. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the furthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most negatively impacted. The EIS recognizes that there is no guarantee wheat grown in the Northwest will be competitive now or in the future because there are many factors that influence international commodity markets (e.g., trade agreements, the U.S. dollar, global supply, etc.). However, the analysis finds that the cost to transport wheat to market would continue to be lower than costs paid by other wheat growers in the United States (e.g., the Dakotas and Midwest). Favorable conditions for Northwest wheat growers that help them stay competitive are: (1) the natural environment of the Palouse region (weather, soils) is ideal for growing this type of wheat, which leads to some of the highest yields per acre in the world, and (2) proximity of Northwest export ports. The Environmental Justice analysis (Sections 3.18.3 and 7.7.20 of the Draft EIS) provides further detail on potential disproportionate effects to Tribal, low-income, and minority populations from each of the alternatives, and finds that some disproportionate effects to agricultural communities may result under MO3 and MO4.
4227	1	Aaron Lieberman	N/A	But whereas the action agencies' plan details the impacts positive and negative across the different alternatives on other industries, including agriculture, including subsidized barging and power generation, Idaho's outfitters, guides, and rural fishing communities were literally and completely ignored from the impact analysis, as was mentioned, despite readily available information. For all management alternatives and their preferred alternative, the economies of recreation and fishing from diving, outfitting, hotels, restaurants, gas stations, boat shops, license fees, and on were not even accounted for, despite, again, existing, publicly available data. The economic and cultural impacts of salmon and steelhead in Idaho must be given full consideration by the federal agencies that control the system. As was also mentioned before, previous EISs included this information, but this newer iteration does not.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The recreation analysis for the EIS considered the broad range of recreational activities supported by the region, including recreational fishing. While the analysis described any potential impacts to recreational fishing visitation, the EIS did not estimate these impacts separately from the overall impacts to recreation, or estimate changes in fishing visitation related to changes in fish abundance. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which are described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. For MO1, MO2, MO4, and the Preferred Alternative (PA), the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the PA and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term.
4228	1	Joseph Bogaard	N/A	One has to do with the process of public comment that's now underway. And of course, it was, in our minds, inadequate to start with, with a very short 45-day comment period for the purposes of receiving comments from the public on a document that exceeds 8,000 pages. This inadequacy and insufficiency on the part of the public comment process has been greatly exacerbated by the public health crisis, you know, caused by the coronavirus. It	The co-lead agencies considered requests to extend the public comment period. This National Environmental Policy Act (NEPA) process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				-- we appreciate the -- this opportunity for the teleconferences in lieu of public meetings, given that health crisis. But it just is undeniable that the -- given the commentary on different perspectives so far on this initial call, these are really big and important issues. And abbreviated or insufficient public comment period without public meetings and without more time, given the important issues and given the reality and disruptions and concerns around the coronavirus crisis, it's just unacceptable. And I'm speaking to the agencies here to encourage you once again to expand the public comment period to include rescheduled public hearings after a better time at which the coronavirus is no longer a threat and people can gather safely.	region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was consistent with NEPA regulations. The CRSO EIS website reminded the public on April 9, 2020, that they should plan to submit comments by the close of the comment period.
4233	1	Keith Kutchins	N/A	This EIS states in the introductory material that the EIS will allow the co-lead agencies and the region to evaluate cost and benefits of the various alternatives. I'm still looking for where that occurred. And in the spirit of several of the other commenters working together, that needs to be done. Otherwise, this EIS as drafted is flawed. As the first caller mentioned, Kurt Miller, Executive Director of Northwest River Partners, he mentioned -- I don't know if the number is right or not -- but if restoring the lower Snake to natural condition cost $1 billion, that's yet but a drop in the hat compared to the value of the natural capital in the Columbia River Basin is $198 billion a year.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional, and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in National Environmental Policy Act (NEPA) analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making consistent with NEPA (see 40 C.F.R. 1502.23). Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Table 7-1 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a number of the resource areas as well as the implementation costs of the alternatives.
4237	1	Marvin Entel	N/A	But anyway, the other question that I had is that the foreign fishing factories that are fishing off of our coast, it's my understanding that some of these foreign fishing ships take up to 600 ton of fish from the ocean in their (indiscernible). I have never seen any documentation about the number of tons of fish that the foreign fishing factories take from the -- they're supposed to be on the 200-mile limit, but often they get into the 100-mile limit. But there's no indication of the number of tons of fish that these foreign fishing factories take from the ocean that are stealing our fish that we send there.	While harvest rates certainly have an effect on salmon populations, the co-lead agencies did not do an in depth analysis of those effects in the Draft EIS. The National Marine Fisheries Service conducted a complete analysis of harvest in a recent EIS. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
4239	1	Amelia Gucker	N/A	My second point is that the collection of the mortality rate -- or the reporting of the mortality rate at the dams was significantly under-reported. According to biological standards of collection of fish mortality and (indiscernible), fish -- juvenile fish that are in stress or dying or dead migrate to the bottom of the raceways instead of floating to the top. It was standard practice to collect only the floating mortality of the juvenile salmon, at which point the juvenile salmon would only float if they've been dead for two to three days when the body organs began to bloat and causing the flotation. In my work at the dam, when I attempted --made a action to collect the mortality of fish at the bottom of the raceways versus only the floating mortality, it was significantly higher by a factor of about 10 to 1. So that -- the methods used by the biologists at the dams were —- okay -- were significant to under-report the mortality of the juvenile salmon.	The mortality rate the commenter is referring to is in the raceways which are at dams where fish are collected and transported. These dams are Lower Granite, Lower Monumental, and Little Goose.The commenter is correct that in the raceways, as well as in the transport barges, some fish that die sink to the bottom of raceways and tanks and are not included in facility mortality counts taken by the site staff. However, to assess the benefits of transport, versus in-river migration, returns of adult PIT-tagged fish are used, not facility mortality data. Smolt-to-Adult return rates (SARs) of fish known to migrate in-river versus fish known to have been transported show that transportation generally benefits Snake River hatchery and natural origin steelhead and spring/summer Chinook salmon.
4249	1	Nicholas Garcia	N/A	We have a technical question about the EIS. Specifically, we want to better understand the criteria you used to evaluate whether an alternative met the -- one of the fundamental objectives. And for example, the preferred alternative was indicated to meet -- that provides reliable and economic power supply. But this is despite the fact that it has a 160-megawatt decrease in the amount of power production, and we don't understand how the conclusion was made that it met the standard, despite the reduction in power production.	Table 7-1 in Chapter 7 summarizes how each alternative met or did not meet the objectives. As most objectives were to improve a specific resource condition, then analysis that demonstrated improvement was deemed successful in meeting that objective. The Preferred Alternative (PA) was deemed to have met the objective of supplying an adequate efficient, economical, and reliable power supply because the alternative has essentially the same reliability of the Northwest power system without needing additional resources. Overall, hydropower would decrease relative to the No Action Alternative under the PA. However, because of the shape of the remaining hydropower generation in the PA, the loss of load probability (LOLP) was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary. The Bonneville wholesale power rate pressure is estimated to be 2.7 percent relative to the No Action Alternative. A portion of that rate pressure has already been incorporated into the BP-20 wholesale power rates; and, the remaining rate pressure likely falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control.
4249	2	Nicholas Garcia	N/A	A similar question rolls around the emissions of carbon. The -- it -- the EIS indicates that it marginally met -- the preferred alternative marginally met the carbon reduction goal. However, carbon emissions would go up under the preferred alternative. So we don't understand just how the criteria was applied and that particular conclusion was made.	The EIS finds that under the Preferred Alternative, power sector greenhouse gas (GHG) emissions would increase by about 0.7 percent relative to the No Action Alternative. A discussion has been added to Chapter 7 Preferred Alternative regarding the degree to which this objective is not met, as compared to the other alternatives, including the No Action Alternative.
4250	1	Scott Simms	Public Power Council PPC	Northwest Public Power rate payers have a sterling track record of paying for its fair share of federal hydro mitigation responsibility. In fact, one can argue these investments have included quality-of-life benefits and positive environmental and commerce benefits that reach beyond our mitigation obligation. Yes, hatcheries, habitat, hydro, and harvest -- we have funded, and are still funding, all of the Hs. We in Public Power remain committed to upholding our fair share of the mitigation cost in the Basin. But the key words here are "fair share." The preferred alternative in this Draft EIS advances a number of proposed changes in system operation. Our comment is that any new costs resulting from these proposed actions should be equitably allocated and not borne exclusively by BPA's Public Power customers. Specifically, to the extent the preferred alternative results in additional costs allocated entirely to Public Power, it is time to find ways to build on existing federal law to more broadly share these regional costs. Not only is it appropriate to equitably align cost responsibility with public benefits, but doing so also recognizes the region's shared stake in both fish recovery and the financial health of BPA. Again, the Draft EIS is a starting point, and it creates an opinion for parties to find tangible measures to fund the cost impacts of these operation's changes rather than the usual default of sending the cost straight to the hard-working men and women who pay their bills to community-owned Northwest Public Power utilities.	For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore, already include a substantial portion of the cost pressures found in the Preferred Alternative. The financial responsibility for fish mitigation is not solely allocated to Bonneville's power ratepayers as the comment suggests. Fish mitigation costs are assigned to each authorized project purpose based on each purposes overall share of project costs, as determined by the cost allocation, by recovering those costs through power rates. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Congress also granted Bonneville discretion to fund the power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992, in some situations, including the Columbia River Fish Mitigation program. (Energy Policy Act of 1992, Pub. L. No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)). Bonneville generally does not, however, directly pay for the capital costs of fish mitigation structures; instead, it reimburses the U.S. Treasury for the power share of appropriations used to construct the structure. Additionally, as described in Section 3.19 of the EIS and Appendix Q, funding to operate the system comes through multiple mechanisms, including Federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. For joint related costs, including funding for fish and wildlife mitigation actions, the Corps and Reclamation receive annual congressional appropriations to fund most, if not all, capital investments. Bonneville reimburses the U.S. Treasury for the power share of these appropriations. Once the investment is in place, Bonneville will typically direct fund the power share of the operations and maintenance costs associated with the facility. In addition to congressional appropriations for fish and wildlife and costs directly funded to Corps and Reclamation by Bonneville, the Bonneville Fish and Wildlife Program (which is separate and distinct from direct funding described above) funds hundreds of projects each year to mitigate the impacts of the Federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the Federal Columbia River Power System (FCRPS). Bonneville uses its authority under 16 U.S.C. 839b(h)(10)(A), to make expenditures to implement its Fish and Wildlife Program. These expenditures provide system-wide funding for actions that also mitigate for the non-power purposes of the CRS, so Bonneville recoups the non-power share of those expenditures from the U.S. Treasury as credit, as required under 16 U.S.C. 839b(h)(10)(C). Bonneville's Fish and Wildlife Program expenditures incurred mitigating the CRS operations identified in the Final EIS and adopted in Bonneville's Mitigation Action Plan would continue to be allocated and borne as provided by existing laws governing the FCRPS and the long-standing accounting procedures used to implement them. As described in Chapter 7 of the EIS, funding decisions for Bonneville's Fish and Wildlife Program are not being made as part of the CRSO EIS process. Future budget adjustments would be made in coordination with the regional entities that help Bonneville implement its Fish and Wildlife Program.
4251	1	Rodney Cawston	Colville Confederated Tribes; Confederated Tribes of the Colville Reservation	I just hope that there will be consideration given to extend the deadline for submission of comments, you know, for the CRSO EIS.	The co-lead agencies considered requests to extend the public comment period. This National Environmental Policy Act (NEPA) process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website reminded the public on April 9, that they should plan to submit comments by the close of the comment period.
4256	1	David Ortman	N/A	A search of the DEIS chapters has not turned up any analysis, for example, of the Columbia River Systems Operation on the Yakima River. Yet we know that, partially due to the lower Snake River dams, excessively high temperatures of lower Columbia killed off returning sockeye in 2015 as well as in 2018 when the lower Yakima River itself had observed 12 80-degree days in July.	The scope of the Draft EIS is limited to the geographical area affected by the operation, maintenance and configuration of the Columbia River System projects. The Yakima River is not directly affected by the projects, but the effects to the populations of anadromous salmonids that use the Yakima River are analyzed in Section 3.5.3 for each alternative under the subheading "Middle Columbia River Salmon and Steelhead." CSS modeling was not available for populations outside of the Snake River. National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models were available for Upper Columbia populations, but not Middle Columbia. Results from the COMPASS and Lifecycle models of Upper Columbia populations were used as a surrogate for Middle Columbia salmon and steelhead, including those in the Yakima River.
4257	1	Mike Gonzalez	N/A	If the dams were breached, we expect the cost of power to increase as much as 30, 40 percent. That would be devastating in a county where many residents are on strict budgets and considered low income. Seventy percent of our customers are Hispanic. For nearly 30 percent, English is a second language.	The magnitude of power rate effects described in the comment are consistent with the highest estimated effects under MO3 that could be experienced by Bonneville's utility customers. As described in Section 3.7.3.5 of the Draft EIS, the implications of the cost of electricity to end-users (such as residents and businesses) is upward rate pressure ranging from 1.6 to 3.6 percent relative to the No Action Alternative. The Environmental Justice analysis for MO3 in Section 3.18.3, describes that energy burdens in Region C are already likely unaffordable for all households with incomes below the Federal poverty level, and thus any upward rate pressure could impact low-income households for whom energy costs are a larger percentage of their income.
4262	1	Michael Kindall	N/A	That plan I was describing goes back to when we had Governor Andrus within the State of Idaho. And he and his friend that retired from the Forest Service had come up with this plan to have a floating tube that would facilitate moving the young fish at the proper level, dependent -- all dependent upon temperature so that the fish would not get injured on their way to the ocean. This plan was developed by the two of them that knew the -- this was a solution to this ongoing problem that has been discussed to death. For some reason at that point in time, this proposal that they came up with was not gone ahead with. Perhaps all of you that are in charge now have never even heard of this proposal. That is the reason why I called. I want you to hear the proposal, I want you to look it up, and I want you to see if it is a solution now. I see the steelhead and the salmon coming to extinction without doing something proactive. This is a very proactive plan, and I believe in this particular case -- and so did Governor Andrus and his friend that retired -- he was a biology guy. He retired from the Forest Service or who knows where. They came up with a great plan. Please look back into history to see what their plan was because, like I said before, we have that technology.	The commenter is correct that the co-lead agencies are not familiar with this specific plan developed by Governor Cecil Andrus. However, the Corps of Engineers has conducted Engineering Alternative Studies for each of the lower Snake and Columbia River dams that did examine similar approaches as well as many other innovative approaches. The major challenges for most of these ideas is the extreme difficulty of collecting substantial numbers of fish and safely moving them into the conveyance system. However, these ideas have led to structural changes to benefit fish passage including, spillways weirs, better bypass outfalls, and the other improvements in juvenile migration over the past 25 years.
4263	1	Keith Kutchins	N/A	Comments -- this EIS will provide for the -- it says in this EIS its operating agencies in the region will work together to evaluate the cost and benefits of the four lower Snake dams, and I'm not finding where that evaluation is or how it was performed. There's a tremendous debate on whether or not those four dams pay their own way, whether or not their revenues, the amount of money they generate, exceeds the amount of money it costs to keep them	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in National Environmental Policy Act (NEPA) analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making,

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				in operation. There are studies, some studies, that indicate it cost at least $100 million a year in excess of their worth, up to maybe closer to $200 million a year in excess of what their worth is. This was also indicated in the last system operation review and the associated lower Snake River juvenile salmon migration feasibility study when even the very conservative taxpayers for common sense supported the natural river alternative. So this EIS fails procedurally and substantively if this discrepancy is not resolved.	including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Table 7-1 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four lower Snake River dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170, Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecast direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
4263	2	Keith Kutchins	N/A	The impacts of alternative MO3, the impacts of that alternative to storage reservoir elevations is not complete. In the mid-1990s, the watershed equity team comprised of the Columbia Basin tribes, four state fish and wildlife agencies, and the U.S. Fish and Wildlife Service, and National Marine Fisheries Service, including modeling from the Northwest Power Planning Council, concluded that water velocity travel times met the needs of migrating spring salmon without needing additional flow augmentation from the storage reservoirs, like Grand Coulee, Dworshak, Hungry Horse, and Libby, if the four lower Snake Rivers were bypassed. That allows those storage reservoirs to remain relatively full and stable for other needs, such as resident fish, biological objectives, recreation, irrigation, power production, and flood risk management. So this EIS is flawed unless that alternative MO3 includes this analysis and type of modeling.	The modeling for MO3 was developed by the co-lead agencies, in coordination with multiple cooperating agencies, including former members of the watershed equity team. The modeling for MO3 relies on current, high quality information, including information on flow impacts to anadromous and resident fish species. A range of flow levels, and their impacts to fish as well as other project purposes were analyzed in both Multiple Objective alternative 2 (MO2) and Multiple Objective alternative 4 (MO4) and can be used to assess impacts based on storage reservoir modifications. Changes in flow were not proposed for this measure in an effort to better isolate and assess effects to anadromous stocks based on breaching the four lower Snake River dams from upstream flow-based effects to resident stocks
4264	1	Kristin Meira	N/A	We know that barging is the most efficient and environmentally friendly mode of cargo transportation, and we've heard folks in the past say that folks are leaving the river and that the tonnage numbers are down when it comes to barging. And I wanted to highlight the recent numbers that have come out for 2018, the most recent year that's now available. Tonnage has gone up on the Snake River. And in fact, in 2018, there was over 3.8 million tons of cargo that moved just on that part of our river system. If you wanted to move the cargo that moved on the Snake that year, if you wanted to take it off of barges and put it on trucks instead, it would have been over – or nearly 150,000 trucks that would have been required. And if you wanted to look at railcars instead, it would have taken over 38,000 railcars to move just what moved by barge in 2018 on the Snake River.	Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Pacific Northwest currently and removing that option would increase transportation costs for grain producers, as the EIS shows. Depending on the scenario, truck ton-miles may experience an increase of 19 percent (under Scenario 1, when rail rates are not assumed to increase) to 84 percent (when rail rates increase by 50 percent) under MO3 when compared to the No Action Alternative. Rail ton-miles may increase by as much as 86 percent (under Scenario 1, when rail rates are not assumed to increase) or decrease by 2 percent (under Scenario 2, when rail rates increase by 50 percent). The EIS also found that truck trips could increase, ranging from an additional 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region.
4265	1	Bill Arthur	N/A	My first comment would be to recommend that we extend the public comment period to at least 120 days and to reschedule the public meetings. It's irrational and long to not extend the public comment period, given the complexity and importance of this work and, particularly, a – in the midst of a national, international emergency	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate The co-lead agencies considered requests to extend the public comment period. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
4268	1	Nanette Jones	N/A	We need to breach those dams and take a look at what's happening on the Elwha, the productivity coming back into the river. That's proof that restoring habitat and removing manmade obstacles that stun, disorientate, and kill these migrating fish will improve their numbers.	The commenter is correct regarding success in restoration of spawning habitat and reintroduction into blocked areas following dam removal such as on the Elwha. However, this and other examples do not necessarily have relevance to the lower Snake River Dams. Using some prominent examples in the Pacific Northwest, the Elwha and Condit dams had no passage, and provided few economic benefits. The Draft EIS analysis predicts short term adverse effects including high sediment and low oxygen concentrations that will be harmful to fish as a result of dam breach. However, the Draft EIS also found that in the longer term, the alternative that includes the measure to breach the lower Snake River dams has the greatest predicted benefit for Snake River salmon and steelhead compared to the other alternatives. The EIS set forth eight objectives which, in tandem with the purpose and need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the alternative that includes the measure to breach the lower Snake River dams. However, the Preferred Alternative also meets the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. The alternative that includes the measure to breach the lower Snake River dams, by contrast, has significant regional economic impacts and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend dam breaching because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
4269	1	Jim Wendland	N/A	Have they considered fish hatcheries as a dilemma of solving the salmon runs?For the money it would take to tear down the dams, they could put in an awful lot of fish hatcheries. Has anybody ever studied that?	Hatchery programs have long been a part of the approach for salmon recovery. Based on the EIS analysis of fish in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and the Preferred Alternative is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery programs are proposed. Diversity is an important factor in an ESU's ability to persist and adapt, and is one of the factors considered in assessing an ESU's long term viability, along with abundance, productivity, and spatial structure. There is an extensive body of literature developed from studying these factors and managing the conservation of salmon and steelhead, including hatcheries as one tool. Figure 3-111, which combines hatchery and wild fish, in the Draft EIS was an illustration that the CRS can and has supported large numbers of returning adult salmon and steelhead. Over time, the Preferred Alternative is anticipated to benefit both wild and hatchery fish. Hatchery origin fish are very important to Tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS.
4271	1	Kurt Miller	Northwest River Partners	The DEIS shows that breaching the four lower Snake River Dams without replacing the generating capabilities would double the risk of region-wide blackouts throughout the Northwest. The DSI shows that replacing the dams with a carbon-free generation portfolio such as solar, wind and batteries would increase electricity cost by $1 billion annually, that's billion with a B. That would mean that millions of electricity customers across the Northwest would see their monthly electricity bills jump by 25 percent or more. Our most vulnerable communities would be hit the hardest.	The comment that electricity costs would increase under MO3, which includes the measure to breach the four lower Snake River dams, is consistent with the findings of the EIS. See Draft EIS, section 3.7.3.5, Table 3-166. Reliability would decrease unless and until sufficient replacement resources are acquired. Regarding the comment about the "most vulnerable communities" the Environmental Justice analysis in Section 3.18 of the EIS, provides further detail on potential disproportionate effects to Tribal, low-income and minority populations.
4271	2	Kurt Miller	Northwest River Partners	The DEIS shows that if we replace the lower Snake River Dams with less expensive fossil fuel resources, they would add three million metric tons of carbon to the atmosphere each year. Given worldwide declines in salmon populations due to warming and acidifying oceans, adding more carbon to the atmosphere is definitely a step in the wrong direction.	The agencies analyzed impacts to greenhouse gas emissions, which are identified in Sections 3.8 and 7.7.10. Effects to alternatives and resources from projected changes in climate are analyzed in Chapter 4 and Section 7.8. Greenhouse gas emissions under the Preferred Alternative are less than those expected under Multiple Objective alternative 3, which includes the measure to breach the four lower Snake River dams.
4271	3	Kurt Miller	Northwest River Partners	Beyond electricity, the DEIS shows that breaching the lower Snake River Dams would mean losing tens of thousands of acres of irrigated farmland that thousands of agricultural workers depend on as a source of income.	The comment is consistent with Section 3.12.3, for MO3, in Region C that pumps are unable to deliver water to an estimated 47,926 acres. MO3 was not identified as the Preferred Alternative in the Draft EIS.
4271	4	Kurt Miller	Northwest River Partners	The DEIS estimates that the region would lose $458 million in social welfare as a result.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the MOs. This comment is consistent with the findings in the EIS for Social Welfare Effects for irrigation under Multiple Objective alternative 3 in Section 3.12.3.4.
4273	1	Robb Krehbiel	N/A	We support breaching the four lower Snake River Dams and view it as a necessary action to prevent the extinction of the southern resident Orcas. However, any dam-breaching action must be coupled with infrastructure investments to support local communities and economies as they transition. Through forums like Governor Inslee's lower Snake River stakeholder process, people identified the investments needed, including expanded rail lines, extending irrigation lines, installing renewable energy and increasing energy efficiency. Unfortunately, the DEIS does not provide this holistic package of solutions and instead has chosen to maintain the status quo. The DEIS also fails to fully or accurately consider southern resident Orcas. The DEIS states that Snake River salmon runs are not important to the orcas. This is in conflict with the best available science. The country's leading southern resident Orca scientists have clearly stated that the four lower Snake River Dams must be breached if we hope to prevent the extinction of these Orcas. According to a study by NOAA and the Washington Department of Fish and Wildlife, two of the ten highest priority salmon runs for the southern residents are Snake River runs. GPS data from NOAA also shows that during the winter and spring, the orcas spend a considerable amount of time at the mouth of the Columbia River, foraging for salmon returning to both the Columbia and Snake Rivers to spawn.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). Changes to the portion of the whales food availability on the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but will not change their overall condition or population dynamics. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS. The Draft EIS meets the requirements of NEPA, as outlined in 42 U.S.C. 4331, et seq., 40 C.F.R. Parts 1500 1508 (CEQs regulations for implementing NEPA), and co-lead agency specific NEPA regulations. The Draft EIS' effects analysis of each resource is based on best available existing information as stated in Section 3.1.1. If MO3 were selected and authorized by Congress, then additional studies and site-specific NEPA analysis would be needed to provide the level of detail requested in this comment.
4273	2	Robb Krehbiel	N/A	The DEIS fails to fully assess climate change, and we request that the agencies add an assessment of the impact to (indiscernible) of increasing reservoir temperatures under various climate change scenarios. With climate change, the number of days where reservoir temperatures reach lethal levels to salmon is expected to increase. Independent research has stated that removing these four dams would ameliorate this hot water problem and increase salmon access to over 4,000 miles of free flowing, climate-resilient, federally-protected spawning habitat in central Idaho.	The CRSO EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives' effects on Snake River stocks, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Regarding climate change, the climate science community is still developing models to the resolution required to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at this time. Therefore, it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3). Regarding water temperatures under dam breach scenarios, the analysis of MO3, which includes breaching the four Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The models showed minor changes in the Columbia River under the dam breach scenario alternative. Without a reference to the independent research, the co-lead agencies cannot verify the statement regarding removal of the four dams.
4273	3	Robb Krehbiel	N/A	Lastly, I would ask that the agencies extend the comment period beyond 45 days, as that is a very short period to review 8,000 pages, especially in light of the current public health crisis.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website reminded the public on April 9 that they should plan to submit comments by the close of the comment period.
4274	1	Colleen Weiler	N/A	My comment is specific to the southern resident Orcas and the lack of information provided in the DEIS on this population. It only includes three sources of information for the southern resident Orcas and fails to incorporate the significant data collected by the National Marine Fishery Service that shows the mouth of the Columbia River as a hotspot for the orcas, particularly in the late winter and early spring when spring Chinook are congregating to return upriver. It also does not include information on the coastal prey sampling for southern resident Orcas, which further supports their preference for Chinook salmon in coastal waters, with over 60 percent of the samples Chinook salmon and more than half of those Chinooks from the Columbia River Basin. It is evident that the Columbia River Basin is a critical and seasonally important food source for southern resident Orcas. The primary threat to the thinning population of whales is a lack of adequate availability of Chinook salmon throughout their range, and the subsequent nutritional stress can cause negative individual and population level effects. Without enough food available now, the orcas are struggling just to survive, and they have no chance of recovery without increasing Chinook abundance throughout their range. The Columbia and Snake Rivers are a vital source of salmon for these whales, and the recovery potential for those salmon is significant in the Columbia River Basin. With the minor changes purposed in the DEIS, it maintains a status quo that will lead to the extinction of salmon and Orcas and maintains uncertainty in communities connected to the watershed and its salmon.	The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. SRKW analysis is described in the EIS, including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. This includes information on seasonal food sources and coastal waters as discussed below. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale (SRKW) would result from implementing MO3, which includes the measure to breach the four lower Snake River dams. This conclusion is based on the fact that Chinook salmon available to SRKW from the lower Snake River comprises only a small percentage of their overall diet. Changes to this portion of the whales food availability of the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but will not change their overall condition or population dynamics. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by the U.S. Fish and Wildlife Service.
4275	1	Scott Simms	Public Power Council PPC; Public Power Council (PPC)	Today I'd like to focus on the matter of juvenile salmon survival rates, an issue that appears to be the center of much debate in our region when it comes to current and future Columbia River System operations. A great deal of misinformation is leading to a misunderstanding among some about sources and investments in juvenile salmon production and the many factors contributing to juvenile salmon downstream mortality. In fact, many people are unaware that successful downstream juvenile passage rates through the federal hydrosystem are comparable to natural rates of mortality in an undammed river. Because of these misinformed impressions, I'd like to request that the federal co-lead agencies provide for the final CRSO EIS, a table of all known sources of juvenile salmon production and mortality in the Columbia River System. This is not a request for new analysis. This is a straightforward accounting request in the spirit of transparency so that the public can see the vast investments of millions of dollars and corresponding millions of juvenile salmon produced in this basin every single year, thanks to taxpayers, electricity rate payers, tribes and private parties.	The Draft EIS describes and acknowledges the multitude of factors that affect salmon and steelhead throughout their life cycle in the Affected Environment. Some factors, such as predation, disease, natural causes, etc. were discussed very briefly and more detail is incorporated by reference from NOAAs Biological Opinions in 2008, 2010, 2014, and 2019. The analyses used in this EIS were for the purposes of comparing the effects of the action alternatives for operation and configuration of the CRS projects to one another and to the No Action Alternative. To the extent that the different alternatives affect these processes, metrics were developed to measure changes; they were described in Section 3.5 qualitatively, and, in some cases, data was built into the fish models to be sensitive to these relationships. Of course, factors such as travel time and direct mortality from dam passage are most notably different among the alternatives and, as such, are discussed in more detail. Likewise, hatchery programs that produce salmon and steelhead are also mentioned briefly as part of the picture, but not the focus of analyses.

4275	3	Scott Simms	Public Power Council PPC; Public Power Council (PPC)	As well, in the spirit of transparency, let's have the co-lead agencies shine the light on all the sources of juvenile mortality in the final CRSO EIS. Public power and tribes are aligned on the fact that avian predation of juvenile salmon is a leading source of juvenile salmon mortality, but see the numbers for all leading juvenile mortality factors so that together with the production figures we can have honest and informed conversations about factors impacting juvenile salmon in the final EIS.	See response to Comment 4275-1.
4275	4	Scott Simms	Public Power Council PPC; Public Power Council (PPC)	I'm speaking again today to show how easy it is to get back into the queue to make comments in this process. I resubmitted my request at 4:30 p.m., and here it is 20 minutes later. Many parties are attempting to attack the public comment process for this CRSO draft EIS. I want to state for the record today that the public comment process and opportunities for this draft EIS are sufficient, even with recent changes forced by completely unforeseen impacts of the global Coronavirus pandemic. The federal agencies gave sufficient notice for this process and have been transparent and available to all stakeholders in the period leading up to the release of the draft EIS, as well as after its release. There are a variety of channels available for public comments to be shared, whether parties are local, regional, national or international in nature.	Thank you for your comment.
4276	1	Mike Gonzalez	N/A	If the dams were breached, we expect the cost of power in our neighborhood to increase as much as 30 percent, and that would be devastating in a county where many residents are on strict budgets and considered low income.	The comment that electricity costs would increase under Multiple Objective alternative 3, which includes the measure to breach the four lower Snake River dams, is consistent with the findings of the EIS. See Draft EIS, Section 3.7.3.5, Table 3-166. The Environmental Justice analysis in Section 3.18.3 provides further detail on potential disproportionate effects to tribal, low-income and minority populations.
4276	2	Mike Gonzalez	N/A	The Pasco school district is our fifth-largest customer. They spend nearly $2 million a year on power. If rates rise 20 to 30 percent, that's an additional 400- to $600,000 not going towards education in a school district where more than 70 percent of the students are Hispanic, nearly half are considered low income.	The comment that electricity costs would increase under Multiple Objective alternative 3, which includes the measure to breach the four lower Snake River dams, is consistent with the findings of the EIS. See Draft EIS, Section 3.7.3.5, Table 3-166. The Environmental Justice analysis in Section 3.18 provides further detail on potential disproportionate effects to tribal, low-income and minority populations.
4277	1	Margie Van Cleve	N/A	Unfortunately, the CEIS does not deliver the comprehensive solution that Snake River salmon and Northwest communities require. We need a comprehensive plan that works for salmon, orca, farmers, river communities and meets our tribal treaty responsibilities. We need agency and political leadership to advance dialogue that develops a comprehensive and durable solution.	The co-lead agencies agree that there are many effects to salmon and steelhead populations outside the operation of the dams, and outside the authority of the co-lead agencies. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. The Preferred Alternative meets the Purpose and Need Statement and certain objectives identified in the EIS for operation of the Columbia River System. The co-lead agencies are committed to ongoing coordination with stakeholders through a variety of forums. In areas where the co-lead agencies have appropriate authority, we will continue to be strong regional partners.
4283	1	mljackson@clarkston.com	N/A	American family farms produce corn, soybeans, lentils, garbanzo beans, and of course wheat. Ten percent of all the wheat that leaves the United States for foreign locations goes through one of the four lower Snake River dams; 58% of all US exported wheat passes through the Columbia/Snake River system. Family farms feed the world now, but if it costs significantly more to transport their products, they will go out of business. Please see the $4 billion in impacts over the next 30 years to transportation identified by PNWA in its study found at: https://files.constantcontact.com/9a08bcf9001/8768ec34-9437-4adb-badb-477bde47019b.pdf Railroads increased prices dramatically during extended lock closures. If you hand them a monopoly by eliminating dams, prices will skyrocket. There is a shortage of truck drivers today, when there are three options for moving freight. If the range of options is narrowed down to only two, and those two are already inadequate, youre not going to have a good outcome. You can only put so many cars on the railroads. The right cars are not where they are needed (wheat requires Class A rail cars which are in limited supply). The $1.1 billion in needed infrastructure capital investment (also identified by PNWA in its study) is not factored into the CRSO EIS. To leave these costs out simply because they are not in the purview of the action agencies is unconscionable	The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted. The EIS recognizes that there is no guarantee wheat grown in the Northwest will be competitive now or in the future because there are many factors that influence international commodity markets (e.g., trade agreements, the U.S. dollar, global supply, etc.). However, the analysis finds that the cost to transport wheat to market would continue to be lower than costs paid by other wheat growers in the United States (e.g., the Dakotas and Midwest). Favorable conditions for Northwest wheat growers that help them stay competitive are: (1) the natural environment of the Palouse region (weather, soils) is ideal for growing this type of wheat, which leads to some of the highest yields per acre in the world, and (2) proximity of Northwest export ports. Currently, the cost to transport wheat to market is quite low relative to other parts of the United States and world.
4283	2	mljackson@clarkston.com	N/A	It is inappropriate for the Executive Summary to tout recreational fishing gains when neither the CSS or COMPASS models account for the loss of hatchery fish.	The Draft EIS acknowledges that breaching the four lower Snake River dams in Multiple Objective alternative 3, there would no longer be an obligation for Bonneville to fund U.S. Fish and Wildlife Service for the Lower Snake River Compensation Plan facilities, which accounts for much of the hatchery production in the basin and other mitigation activities could be adjusted. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6. The fish models are based upon data collected from past fish runs, and there is no data available to inform an quantitative analysis for wild fish in the absence of hatchery fish. Over time, recreational fishing gains would be expected as wild fish replace hatchery fish, but the timeframe and numbers of fish was not quantifiable for this analysis.
4294	1	N/A	N/A	I am concerned that the number of rail and semi-trucks along the river will have to increase tremendously if the number of barges on the river are reduced. Barge transport is a clean alternative to the increase in train and truck pollution that would occur. Please weigh the benefits of barge transport.	The EIS evaluates the level of anticipated increases in truck and rail traffic that would occur under MO3 which includes a measure to breach the four lower Snake River dams. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent). The EIS acknowledges that depending on how rail rates respond to breaching the four lower Snake River dams, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur under MO3.
4303	1	amyannleslie@gmail.com	N/A	The DEIS itself recognizes that breaching the dams will deliver greater benefits to endangered Snake River fish populations, with greater certainty, than any other considered options. The federal governments current approach is not working for salmon, orcas, or our fishing and farming communities. Taxpayers and regional ratepayers have spent $17 billion on five insufficient Columbia Basin salmon plans over 25+ years, but failed to recover a single endangered population.	The EIS concluded that MO3 would have greater improvement to certain salmon species in the lower Snake River. It did not conclude there was greater certainty of that result in MO3 compared to other alternatives. The conclusions were based on the ranges predicted in two independent models, that have different parameters and limitations in their predictive capabilities. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. The commenters suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at Federal Columbia River Power System (FCRPS) projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96 percent and 93 percent for spring and summer migrants respectively, see Endangered Species Act FCRPS 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15 to 20 percent with losses recorded as high as 30 percent. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish). The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the National Marine Fisheries Service (NMFS) COMPASS model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6 percent due to breaching the four lower Snake River dams, which is a 19 percent relative increase over the No Action Alternative. The NMFS Lifecycle model predicts an increase in adult returns of 13.6 percent for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88 to 1 percent). Results for Snake River steelhead are similar (10 percent absolute improvement, or 23 percent relative juvenile survival increase, Smolt-to-Adult return rates (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River Spring/Summer Chinook is predicted to improve by 10.4 percent due to dam breach, which is an 18 percent relative increase over the No Action Alternative, while SARs would increase by 115 percent (from 2 to 4.2 percent). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8 percent which is a 46 percent relative increase over the No Action Alternative. The CSS model also predicts that SARs increase by 177 percent (from 1.8 to 5 percent). Though differing in predictions, both modeling groups predict MO3, which includes the measure to breach the four lower Snake River dams is the best alternative for salmon and steelhead. One model simply predicts adult return increases an order of magnitude higher than the other.
4304	1	jason.mcandrew@umatillaelectric.com	N/A	The fishing rights and form of fishing the tribes have need to be changed to help preserve the salmon runs along with helping the sturgeon.	Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by State, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so.
4305	1	N/A	N/A	I cannot say that I know of any individual, group, business or organization that can defy federal court instructions five times and do so while perpetuating an ongoing ecological travesty. But such is the case of the Army Corps of Engineers and their reluctance to earnestly, effectively address how Columbia River and Snake River dams negatively impact native salmon and steelhead populations.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative meets the anadromous fish, resident fish, lamprey, hydropower generation, water management, and water supply EIS objectives, while minimizing adverse effects impacts to communities and the economy. It is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
4305	2	N/A	N/A	To then in the midst of the COVID-19 pandemic fail to extend the public comment period for this issue is nothing less than an insult to the many diverse stakeholders who live in and love our world-class watershed and want nothing more than to help craft a creative, inclusive, forward-looking solution.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website reminded the public on April 9, that they should plan to submit comments by the close of the comment period.
4305	3	N/A	N/A	Accordingly, I am joining a host of others to demand that any Alternative Plan effectively address 1) the removal of Snake River dams 2) increasing flow over Columbia River dams 3) restoring sane river ecology and habitat, and 4) ending the persecution of native predators.	The CRSO EIS documents the assessment of benefits and impacts of changes to the operations of the 14 Federal projects of the Columbia River System. Using a multi-disciplinary approach and with the coordination and consideration of our cooperating agencies and Tribes, as well as public stakeholder input, and by using the best available information, the co-lead agencies developed the Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Multiple objective alternative 3 (MO3) included a measure to breach the embankments of the four lower Snake River dams. This alternative was fully evaluated throughout Chapters 3, 4, 5, 6, and discussed in Chapter 7. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Increasing flows as a potential measure was evaluated in the EIS. In particular, the McNary flow measure in MO4 demonstrated significant adverse effects to upper Columbia basin fish and wildlife, as well as cultural resources. As described in Chapters 5 and 7, the agencies are proposing to continue habitat restoration actions described both under the No Action Alternative as well as new mitigation for the Preferred Alternative. Certain native predators adversely affect survival of listed fish species and taking actions to keep a balance is a tool in our strategy. These decisions aren't made lightly and are coordinated with resource agencies such as NMFS and USFWS. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
4306	1	george@ttclabs.com	N/A	If the benefit of removing the dams is to help the salmon and other migrating fish, it would seem that better fish ladders with steady flow of water would be the ideal solution. Removing the dams adds more variation to the flow of water and replaces the ladders with much more significant barriers.	All eight dams on the lower Columbia and lower Snake River dams have significant infrastructure, including fish ladders, spillway weirs, and updated fish passage turbines that allow both upstream and downstream fish passage and do not preclude salmon passage. Specific fish, such as Pacific lamprey, require different passage measures, which are proposed for inclusion in the Preferred Alternative.
4307	1	nouveladam@hotmail.com	N/A	To Whom It Concerns: I cannot say that I know of any individual, group, business or organization that can defy federal court instructions five times and do so while perpetuating an ongoing ecological travesty. But such is the case of the Army Corps of Engineers and their reluctance to earnestly, effectively address how Columbia River and Snake River dams negatively impact native salmon and steelhead populations. Even more disconcerting: To then in the midst of the COVID-19 pandemic fail to extend the public comment period for this issue is nothing less than an insult to the many diverse stakeholders who live in and love our world-class watershed and want nothing more than to help craft a creative, inclusive, forward-looking solution.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website reminded the public on April 9 that they should plan to submit comments by the close of the comment period.
4313	1	N/A	N/A	I would suggest that all nets in the Columbia River be removed for at least 5 years and maybe as long as 10 years to give the salmon time to recover. Remove all commercial fishing in the Columbia River and have our Coast Guard and Navy do their job and stop all illegal fishing within our 200 mile limits enforce.	Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by State, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so.
4315	1	duaneleinbach@hotmail.com	N/A	I hear concerns about the "native fish" runs being eliminated. What makes anyone believe we still have native fish that run in these waters, considering we have used hatcheries at the base of nearly every dam on the Snake and Columbia Rivers for over 40 years. In addition Fish and Wildlife allow farm raised fish to be marketed as Columbia River Salmon and Steelhead. A very important question is: How many years has Washington Fish and Game allowed the integration of Atlantic Salmon farming into the Western States Rivers and coastal areas? The last 2 years unfortunately Atlantic Salmon fish farms on the Northwest Coast (300,00+) have escaped into our Western Waters, again how can we continue to have "NATIVE Salmon"?	This comment is generally outside the scope of co-lead agency authority and is outside the scope of this EIS, which analyzes the effects of operation, maintenance, and configuration of the CRS projects. Hatchery programs have long been a part of the approach for salmon recovery. There are broad ecological effects concerning interactions of wild and hatchery fish, as well as harvest, throughout the basin. However, the actual mechanisms, effects, magnitudes, and processes are very complex and uncertain. The analyses used in the CRSO Draft EIS were for the purposes of comparing the effects of the Multiple Objective alternatives for operation, maintenance, and configuration of the CRS projects to one another and to the No Action Alternative. Hatchery origin fish are very important to tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act. These consultations ensure the hatchery programs are not appreciably reducing the likelihood of ESA-listed species survival and recovery, nor adversely modifying or destroying designated critical habitat. These consultations have resulted in many site-specific reforms to reduce effects of hatchery/wild fish interactions, such as decreasing the temporal and spatial overlap of wild and hatchery fish in integrated programs or transitioning to local broodstock in integrated programs. (Please see the 2014 NMFS Final Environmental Impact Statement to Inform Columbia River Basin Hatchery Operations and the Funding of Mitchell Act Hatchery Programs at http://www.westcoast.fisheries.noaa.gov/publications/hatchery/mitchellact_feis/mitchell_act_hatcheries_feis_final.pdf.) Hatchery programs are included in the No Action Alternative and would be expected to continue under alternatives MO1, MO2, and MO4, and certain hatcheries would continue under MO3. No new hatchery programs are considered as mitigation under any alternatives, but MO3 does include increased hatchery production due to short-term impacts from breaching the four lower Snake River dams.
4317	1	sunsetjam@gmail.com	N/A	Restoring abundant salmon and steelhead and helping our starving Southern Resident Killer Whales (orca) is essential for our Northwest ecosystem and culture. There are now 72 Southern Resident Orcas living in the Puget Sound Region. Their numbers are at a 30 year low. Only half of the young born survive and 70% of the pregnancies fail. Scientist believe the orcas are starving with depleted salmon stocks a contributor to their demise. The DEISs treatment of orca is misleading and inaccurate. The DEIS claims that salmon from the Snake River are only a small percentage of the Southern Resident orcas overall diet and that neither the preferred alternative, nor dam removal, would appreciably benefit orca. Fact is that Southern Resident Orca are almost exclusively fish eaters. 85% of their diet is salmon, with Chinook being their favorite species of salmon.They look for their traditional runs which have been lost. The DEIS also ignores analysis from orca scientists – and even the Agencies' own analysis – that show the Snake and Columbia basin salmon are important to the orcas. Restoring abundant salmon runs would enable orca to access an historically important part of their diet, particularly at critical times of the year when female orcas are pregnant. A restored Snake River is the only action that will enable substantially increased abundance of salmon and allow for an increase in overall food supply for orca.	The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. SRKW analysis has been done and described in the EIS, including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale (SRKW) would result from implementing MO3, which includes the measure to breach the four lower Snake River dams. This conclusion is based on the fact that Chinook salmon available to SRKW from the lower Snake River comprises only a small percentage of their overall diet. Changes to this portion of the whales food availability of the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but will not change their overall condition or population dynamics. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally

					authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by the U.S. Fish and Wildlife Service.
4317	4	sunsetjam@gmail.com	N/A	The DEIS ignores avoided costs and future savings by restoring the lower Snake River Costs such as eliminating the rising capital, operations and maintenance costs for the four Snake River dams,more than $1 billion dollars could be saved . Costs to the rural communities and Tribes in terms of lost fishing opportunities, reduced jobs and incomes. Costs that would be gained in jobs created by the river restoration activities throughout the river system.	The EIS evaluates the system costs to operate and maintain (O&M) the lower Snake River dams, including capital costs, under the No Action Alternative and under MO3. Tables 4-1 and 5-1 in Appendix Q show the costs and cost savings under MO3. There would be approximately $107 million in annual capital and O&M cost savings under MO3 compared to the No Action Alternative for the lower Snake River projects over the 50-year period of analysis. The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The EIS recognizes the importance of salmon to Tribes in a number of sections throughout the document. The Fisheries Section 3.15 as well as Section 3.17, in particular, include discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries Section 3.15.2.1, which includes sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries.
4325	1	N/A	N/A	The EIS used only a subjective alternatives analysis. There was no weighting given to the eight Colombia River System Objectives. For each of the major alternatives, they were only subjectively scored on meeting, or not, the eight objectives. It is highly likely that if a different set of agency analysts worked on coming up with a Preferred Alternative, that there would be a different Preferred Alternative. Similarly, if another organization (like Mitre), were to audit this EIS, they would discover that the analysis of the alternatives would not be repeatable. It would be totally dependent on WHO did the evaluations, and not at all dependent on a WEIGHTED VALUE OF EACH OF THE MAJOR OBJECTIVES. Therefore, the conclusion of this EIS, in creating the Preferred Alternative, is irrevocably flawed and the alternatives should be re-evaluated using an objective process.	The commenter is correct that no weighting was applied to the eight objectives in the EIS. A Preferred Alternative was developed that meets the Purpose and Need Statement as well as certain objectives included in the EIS. Quantitative evaluations were conducted to determine the effects of each of the alternatives when appropriate. In instances where quantitative evaluations were not appropriate or possible, qualitative discussions are included to describe the effects of each alternative. The evaluations are clear, transparent, and repeatable based on high quality information.
4332	1	tammydzi@yahoo.com	N/A	The impacts show that peaking at the claimed level is NOT feasible. The lower Snake River dams were never designed to allow anything more than 15 MW of peaking power (ACOE 2002 Feasibility Study). The unsupported sustained peaking claims are not valid; they need to be removed from the fact sheets.	Contrary to the information in the comment, the 2002 EIS identified the four lower Snake River dams as providing 15 percent, rather than 15 MW, of the FCRPS ramping capacity. The EIS analysis found that the four lower Snake River dams provide upwards of 2,000 MW of sustained peaking capacity. The dams also provide important ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See Draft EIS, Section 3.7.3.5, 3-906, Table 3-160. This amount of peaking capacity is slightly lower than that reported in the 2002 EIS cited by the commenter. The ramping and peaking capabilities are described in Section 3.7.3.5 Potential Replacement Resources and Associated Costs. The EIS relies on historical hydropower data to evaluate the potential generation of the Columbia River System projects including the peaking capability of the four lower Snake River dams. Table 3-160 in the Draft EIS presents the historical sustained ramping capability of the four lower Snake River dams.
4332	2	tammydzi@yahoo.com	N/A	Regarding the lower Snake River dams, their value needs to be based on the value they's shown in the past 50 years, and not with "proposed additional capabilities".	The EIS power analysis relies on historical data regarding the ramping and flexibility of the four lower Snake River dams. Table 3-160 in Section 3.7.3.5 in the Draft EIS, presents the historical sustained ramping capability of the four lower Snake River dams. In addition, Section 3.7.3.5, pages 3-905-907 in the Draft EIS, describes how Bonneville used historical rate case values to estimate the value of the historical generation profile of the dams.
4340	1	owyheeriver@comcast.net	N/A	Two often, the case for salmon restoration and the removal of the four Lower Snake River (LSR) dams has been presented as a choice between jobs or fish. Its a false choice. Restoring the river habitat to its natural state will benefit the salmon, people, wildlife in the river corridor, and the industries that rely on a healthy fishery. The four LSR dams were built primarily to enable barging to Lewiston, creating a false inland port in the land-lock state of Idaho. Between year 2000 and 2015, freight transport on the Lower Snake River has declined 69%, container shipping on the LSR has ceased. The lower Snake waterway is even categorized by the Corps of Engineers as a waterway of negligible use. While freight volume continues to trend down, the costs of maintaining the waterway continues to climb. If there is an economic case to be made, the cost-benefit of removing the four LSR dams favors removal. In the development of the 2002 LSRFR the Corps hired noted economist John Loomis to identify any increased economic value to the region from the breaching of the LSR dams. A reanalysis of the LSRFR by the highly respected non-profit Earth Economics revealed that the Walla Walla District misinterpreted Loomis work, and had they accurately interpreted it, the region stood to gain an average annual $1.5 billion in recreational dollars for businesses and the tourism industry, especially in north central Idaho and eastern Washington. Enabling the LSR dams to produce energy was an after-thought, and these four dams provide only 4% of the regions power, which has been replaced by wind & solar power. Additionally, there is reduced demand on the BPA power grid from California as they have moved to wind and solar power.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics, when appropriate, throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative (PA) is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the PA also meets most other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which are described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. Finally, while the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System from which Bonneville markets power. The power generated from the four lower Snake River dams is used to meet Bonneville's collective power obligation, most of which is sold to meet the loads of publicly owned utilities, such as municipalities, rural utilities, and public utility districts. (See Draft EIS Section 3.7.2.5, Bonneville Power and Transmission Customers).
4340	2	owyheeriver@comcast.net	N/A	Taxpayers and regional ratepayers have spent $17 billion on five insufficient Columbia Basin salmon plans over 25+ years, but failed to recover a single endangered population.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Similarly, the Northwest Power Act does not obligate the co-lead agencies to recover ESA listed species or to ensure restoration of other fish and wildlife. Instead, the co-lead agencies fish and wildlife mitigation responsibilities under Northwest Power Act are more limited primarily, managing and operating FCRPS projects, which includes the CRS, to protect, mitigate, and enhance (as opposed to recover) fish and wildlife affected by such projects in a manner that provides equitable treatment with the projects other authorized purposes and consistent with the purposes of the Act and applicable laws. In addition, Bonneville has a specific responsibility to fund protection, mitigation, and enhancement of fish and wildlife to the extent affected by development and operation of FCRPS projects consistent with the Northwest Power and Conservation Councils (Council) fish and wildlife program, the Councils power plan, and the purposes of the Act, which includes assurance of an adequate, efficient, economical, and reliable power supply. Therefore, contrary to the comments broad assertion, the Northwest Power Act does not make Bonneville responsible for funding the regional effort to recover wild salmon and steelhead. The commenters suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at Federal Columbia River Power System (FCRPS) projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96 percent and 93 percent for spring and summer migrants respectively, see Endangered Species Act FCRPS 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15 to 20 percent with losses recorded as high as 30 percent. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
4340	3	owyheeriver@comcast.net	N/A	A new approach is urgently needed. We suggest that the government could instead spend the money compensating the vested economic interests (Port of Lewiston, barge companies, irrigators, and farmers), for their losses due to this change in federal policy, and offer retraining to employees for 21st century jobs.	NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse effects of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities.
4340	4	owyheeriver@comcast.net	N/A	The proposed flexible spill plan is not sufficient to save salmon populations, especially because flex spill will not significantly reduce the transit time of juvenile fish, as shown from the implementation of a similar Flex Spill plan in 2019. One of the issues with flex spill is that it provides the Corps with the flexibility to spill when hydro needs are low, which is usually during the day,while salmon migrations are often highest at night, when spill is lower, reducing its beneficial effects.	The CSS model, predicts that Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead with median values well above 2 percent (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. While the Draft EIS analysis did consider and present juvenile fish travel time through the Columbia River System, the benefit of flexible spill to salmon and steelhead relies largely on reduction in the proportion of fish passing through powerhouses, which in theory will result in increased SARs. Therefore in-river survival and travel time does not tell the whole story. It will take years to understand the true effect because adult returns are required to measure the key effect, SARs. The Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as an assessment and management of adverse unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
4340	5	owyheeriver@comcast.net	N/A	Southern Resident Orcas depend on abundant salmon for their survival, andbest available science says that breaching the lower four snake river dams gives Southern Resident Orca the best chance for recovery. The DEIS says that breaching the dams would have a negligible effect for orca, but the orca	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				scientists have repeatedly advocated for the breaching of the lower four Snake River dams to restore the salmon populations that the orca depend on as their main source of food.	FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). Additional details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
4340	6	owyheeriver@comcast.net	N/A	The Draft EIS fails to honor our treaty promises. Native tribes are more than simply river stakeholders as they have inherent rights as first people. Native nations also have treaties with the United States government which gives them sovereign status. Indigenous people gave up thousands of acres of their land for the right to hunt and fish in their usual and accustomed places, a promise which has not been kept by the government. Restoring salmon runs honors these agreements and the moral imperative for justice. We must honor our commitments to the Nez Perce, Shoshone-Bannock, Umatilla, Warm Springs, and Yakama Tribes.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations treaties impose. The co-lead agencies accordingly included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making.
4351	1	kjwientjes@hotmail.com	N/A	I have to believe that there are alternative solutions to solving the Salmon situation that would be agreeable to all parties involved in this situation. One Idea would be releasing water out of the dams at critical times to help the fish. Another idea would be to improve the fish ladders to improve the migration of these species of fish.	The Draft EIS Preferred Alternative does propose flows for fish, including increasing spill at the eight lower Columbia River System dams, as well as improvements to fish ladders. The Preferred Alternative also proposes to continue operations to augment flows from storage projects during key fish migration periods.
4364	1	megan.holloway80@gmail.com	N/A	The best option for the salmon was Option M03 which required breaching the dams. Model estimates for MO3 showed the highest predicted potential smolt-to-adult returns (SARs) for Snake River salmon and steelhead among the alternatives. Breaching of the lower Snake River projects would have major long-term beneficial effects to resident fish in the Snake River due to improved rearing and migration conditions.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the National Marine Fisheries Service (NMFS) COMPASS model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6 percent due to breaching the four lower Snake River dams, which is a 19 percent relative increase over the No Action Alternative. The NMFS Lifecycle model predicts an increase in adult returns of 13.6 percent for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88 to 1 percent). Results for Snake River steelhead are similar (10 percent absolute improvement, or 23 percent relative juvenile survival increase, Smolt-to-Adult return rates (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River Spring/Summer Chinook is predicted to improve by 10.4 percent due to dam breach, which is an 18 percent relative increase over the No Action Alternative, while SARs would increase by 115 percent (from 2 to 4.2 percent). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8 percent which is a 46 percent relative increase over the No Action Alternative. The CSS model also predicts that SARs increase by 177 percent (from 1.8 to 5 percent). Though differing in predictions, both modeling groups predict MO3, which includes the measure to breach the four lower Snake River dams is the best alternative for salmon and steelhead. One model simply predicts adult return increases an order of magnitude higher than the other. For resident fish, breaching of the four lower Snake River projects would have major long-term beneficial effects to resident fish in the lower Snake River; however during the breaching, major short-term adverse effects would occur.
4369	1	mgrotbo@ravallielectric.com	N/A	We are concerned with the science of 125% spill. We should trust the science. There was a reason we originally settled on the spill amounts. There is a reason it has the name of 100% spill. Science got us there. Why are we letting political pressure move us to a place which will harm fish? If prior science showed about 100% harmed fish, what changed in the science? In closing, we are in support of rejecting MO-3 and MO-4. We ask that you take a holistic view of the problem. We encourage the report to re-evaluate the science of 125%.	Total Dissolved Gas (TDG) levels are regulated under the Federal Clean Water Act, and administered by the States. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125 percent of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a 5-year "standard modification" and Washington issued a permanent rule change, approved by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125 percent. However, as noted by the commenter, there is considerable uncertainty in the effects; and therefore, monitoring was required by the states and EPA to ensure any adverse effects are detected and allow for adaptive management. Migrating salmon and steelhead may spend sufficient time at depths that will compensate for the high gas levels. However, fish and other organisms that spend extended times in less than a few meters of depth are at high risk. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia River Basin. The effectiveness of the spill program will be monitored and effects from other sources such as harvest, ocean mortality, and straying will also be accounted for to the extent possible.
4385	1	willhartindc@hotmail.com	N/A	ICUA also rejects any proposal that will lead to blackouts. The DEIS concludes the dam breaching alternative would more than double the regions risk of power shortages. In addition, both the Northwest Power & Conservation Council and the Northwest Power Pool have issued serious warnings over the possibility of regional blackouts and resource adequacy issues facing the region.	The comments about the importance of the four lower Snake River dams for regional power reliability are consistent with the EIS findings. The EIS finds that, unless and until replacement resources are constructed, MO3 would lead to a doubling of the risk of regional power shortages with the current fleet of other resources in the region. See Draft EIS, Section 3.7.3.5, Table 3-166; and Appendix H, Table 2-1. With additional coal plants slated for retirement, the EIS finding is consistent with the comment and the Northwest Power and Conservation Councils findings of a high risk to regional resource adequacy. The Preferred Alternative improves system reliability while Multiple Objective alternative 1, MO3 and Multiple Objective alternative 4 did not meet or only partially met the objective to maintain a reliable and affordable power system.
4385	2	willhartindc@hotmail.com	N/A	The Pacific Northwest has a legacy of clean energy, and according to the DEIS, breaching the dams would create a 10% increase in power-related emissions across the Northwest. This is unacceptable during a time of continued climate warming which has caused severe adverse ocean conditions for fish.	The co-lead agencies thoroughly analyzed the impacts of the measure to breach the four lower Snake River dams, including effects to emissions, and did not include the measure to breach the four lower Snake River dams in the Preferred Alternative.
4397	1	djpotter@hotmail.com	N/A	The Preferred Alternative in the Draft EIS does not adequately provide for salmon and steelhead populations because it will not improve smolt to adult turn rates (SARs) to levels identified by scientists as necessary for harvest or recovery. Harvestable populations need a SAR around 4%, meaning 4 adults return for every 100 juvenile fish that head to the ocean. Under the Preferred Alternative, SARs for Snake River spring Chinook will reach 2.7% at best.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				The predicted SAR is even lower for Snake River steelhead at 2.4%. At worst, The Life Cycle Model predicts an extinction trajectory under the Preferred Alternative with a SAR below 1%.	and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies used current, high quality information in the EIS analysis. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia River Basin. The 4 percent average SARs target referenced refers to the Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia River Basin, the Councils recovery goals are shared by many parties. Based on the analysis, the Preferred Alternative will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects.
4397	2	djpotter@hotmail.com	N/A	When evaluating the economic impacts of each alternative, the analysis completely ignored the sportfishing economy and its estimated contribution of over $757 million in Idaho alone (over $2 billion region-wide). The Draft EIS relied on a qualitative, rather than quantitative, analysis to evaluate impacts despite the existence of several current studies on the economic contributions of outdoor recreation and sport fishing in states with salmon and steelhead. This is in contrast to water supply, irrigation, navigation, and hydropower generation, which were all evaluated quantitatively.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. In instances when quantitative evaluations were not appropriate or possible, qualitative discussions are included to describe the effects of each of the alternatives. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the MOs, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MO alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
4397	3	djpotter@hotmail.com	N/A	It is unacceptable that the Draft EIS did not use publicly-available data sources to quantify the devastating financial impacts of declining salmon and steelhead populations on rural communities in Idaho and the Pacific Northwest.	The EIS used high-quality information to produce and inform the analysis. The co-lead agencies also had cooperating agencies on their technical teams to bring relevant information and data to the analysis. The Preferred Alternative is not anticipated to contribute to a decline in salmon and steelhead populations, and indirectly, have an adverse affect to communities in Idaho. In fact, it is anticipated to improve salmon and steelhead returns. For a full analysis, see Chapter 7. Additionally, the EIS described the potential effects to recreational fishing, an industry reliant on fish abundance, qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively in the EIS for each alternative.
4416	1	mwgillenwater@gmail.com	N/A	1) I find the draft EIS to be fatally flawed with regards to science and economics because it did not complete the analysis of the effects of climate change on river temperatures and salmon.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia River Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia River Basin in still under development and was not available for this EIS. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, there are not reliable models at this time at the required resolution (river-scale vs. global or regional scale). This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). Chapter 7 discusses the potential climate effects by resource under the Preferred Alternative.
4427	1	troutdna@gmail.com	N/A	The Preferred Alternative merely extends river management measures that have not worked to restore wild fish over the last 25 years. These failed efforts have been well documented. Wild Snake River salmon and steelhead listed under the provisions of the Endangered Species Act represent less than 2% of predevelopment numbers. Each species contains over two dozen unique sets of genes that resulted from thousands of years of adaptation. Are they worth saving? The federal agencies do not think so, saying it would be too expensive. The federal agencies will do anything to protect the four lower Snake River dams and have slanted the Preferred Alternative to do so. They have already sunk 17 billion dollars into failed fish mitigation.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes, including Section 7 of the Endangered Species Act. Under Section 7(a)(2) of the ESA, the co-lead agencies must insure that any action authorized, funded, or carried out is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of habitat of such species. Section 7(a)(2) does not require the co-lead agencies to take affirmative actions to recover ESA-listed species. Regardless, the co-lead agencies included objectives in the EIS to benefit ESA-listed species. The Preferred Alternative meets the requirements of Section 7(a)(2) and meets most of the objectives of the EIS. The spill operation for juvenile fish passage that is included in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on the fish analysis described in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species. For example, the CSS and COMPASS models predict that power house encounters will be cut in half relative to the No-Action Alternative for Snake River spring/summer Chinook salmon. The real uncertainty lies in the hypothesis that reduced powerhouse encounters will result in increased adult returns. To address this uncertainty, the Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas (TDG)-related mortality of juvenile migrants. The commenters suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at Federal Columbia River Power System (FCRPS) projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act FCRPS 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
4427	2	troutdna@gmail.com	N/A	Restoration of wild fish requires smolt-to-adult returns (SARs) assessed at Lower Granite Dam of 2 to 6 percent (mean of 4%). That range has been attained only three times in the last two decades. Pristine spawning habitat in the Middle and South Fork Salmon rivers remains nearly unoccupied by adults. Twenty years of research has provided estimates of Middle Fork Salmon River spawner capacity of 48,000 fish. In 2019, only 322 Chinook returned to the Middle Fork of the Salmon River. Passage of wild spring/summer Chinook salmon destined for all tributaries upstream from Lower Granite Dam in 2019 totaled 4723 fish. The trajectory of returns of wild spring chinook and steelhead is toward extinction, not recovery.	Based on the fish analysis, the Preferred Alternative will make a substantial contribution to improving Snake River anadromous fish runs, but broad recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 Columbia River System projects. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates (SAR) would increase for both Snake River spring Chinook and steelhead and would average well above 2 percent (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative (increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase). The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia River Basin. It should be noted that the 4 percent average SAR target referenced refers to the Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia River Basin, the Councils recovery goals are shared by many parties.
4428	1	medischner@gmail.com	N/A	The final EIS must thoroughly consider all those who travel to various rivers that are made more appealing when there are robust salmon and steelhead populations. Recreational tourism is an important economic driver. For me and many others – we will travel regardless of electric costs. We will not bother to travel if there are no fish.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11). The EIS describes the changes to visitation under MO3, including how dam breaching would affect the quality of the recreational experience. In addition, the evaluation of lower Snake River visitation in the long-term considered Dr. John Loomis survey that was completed as part of the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Study and EIS. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region.
4428	2	medischner@gmail.com	N/A	Finally, the process for getting to the final EIS MUST include thorough consultation with Tribal nations and heavily consider their long connection to these aquatic resources and rights in helping manage them.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several Tribes are cooperating agencies on the CRSO EIS.
4428	3	medischner@gmail.com	N/A	Science shows that removing the four Lower Snake River dams is an important tool to recover salmon and steelhead populations, but the DEIS appears to underestimate the benefits this action would have. This should be corrected in the final, with more robust analysis of these important benefits. As it	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				stands, the preferred alternative in the DEIS does not appear to be adequate to restore these populations. In fact, the analysis does not even provide assurance that the preferred alternative will avoid EXTINCTION for some of these fish.	listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies used current, high quality information in the EIS analysis. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia River Basin.
4428	4	medischner@gmail.com	N/A	I also believe the DEIS may not adequately consider alternative energy options to the dams. Although these dams provide relatively cheap power, the environmental costs of this power are not thoroughly considered, and there could be other future options that are not addressed here. In other regions, different sorts of hydropower provide energy that is more fish-friendly and still economical. These are not thoroughly considered	The EIS examined all power resources identified by the Northwest Power and Conservation Council in their Seventh Power Plan. The resource portfolios considered to replace the four lower Snake River dams are discussed in Section 3.7.3.5, pages 3-904-911 in the Draft EIS. The EIS acknowledges that future technology changes may make other options available. See EIS, Section 3.7.3.1, at page 3-816 in the Draft EIS. Further, Appendices H (Chapter 2) and J (Chapter 4) provide additional details on resource selection.
4432	1	KTTECH@FRONTIER.COM	N/A	As far as the fish situation is concerned: the predation of adult salmonids by orcas and sea lions is well documented. But has any consideration been given to addressing the predation of spring smolts by pelicans, terns and cormorants? The islands these birds nest on are littered with pit tags every spring.	The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including reduction of pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. The Preferred Alternative includes a large suite of predation mitigation measures, some of which include maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary. In addition, other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
4435	1	N/A	N/A	Barging is the safe, economic and environmentally responsible way to move commodities. Loss of the dams would not only result in substantial impacts to regional traffic with the addition of thousands more truck trips each year (adding pollution, increased use of fossil fuels, and a infrastructure impacts on roads and bridges) but also a financial loss that would ripple across communities that depend on the River for safe, environmentally responsible, family-wage jobs and industries that are the backbone of state economies. It is estimated that it would cost the region an extra $2 billion dollars in additional transportation costs to replace the loss of barging along the Columbia-Snake-Willamette.	As described in the Section 3.10 Navigation and Transportation, an analysis of the increased costs to shippers (farmers) associated with breach of the four lower Snake River dams was completed, and found that transportation costs for wheat in the Palouse Region would increase from $0.07 to $0.24 per bushel. This would represent an increase in transportation costs of 10 to 33 percent for farmers, though increases for individual farmers could increase by double that amount depending on their location and other site-specific conditions.
4439	1	s.bare@outlook.com	N/A	The final EIS must include a preferred alternative that includes removal of the lower Snake River dams, which, in my humbug's;le opinion, is a viable alternative. Recovery of abundant, healthy and harvestable levels of Snake River salmon and steelhead is not achievable with the dams in place. This is well documented as several decades of failed recovery efforts and billions of dollars have revealed. The agencies should call on Congress to make the necessary investments to replace the dams benefits so we can both recover the fish and maintain a vibrant regional economy.	A range of alternatives were evaluated in the Draft EIS. This included an alternative that included a measure to breach the four lower Snake River dams. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
4439	2	s.bare@outlook.com	N/A	Science consistently supports the removal of the four Lower Snake River dams as necessary to recover robust and fishable populations of salmon and steelhead in the Snake River basin. The DEIS makes it clear that removing the lower Snake River dams is the best option for Snake River salmon and steelhead, but substantially underestimates the level of benefit. The DEIS preferred alternative doesn't even provide any reasonable degree of assurance that it will avoid extinction of these keystone species, let alone recover Snake River salmon and steelhead to abundant, harvestable levels.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies used current, high quality information in the EIS analysis. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of the Northwest Power and Conservation Council's recovery targets for the region). The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
4449	1	lorifrand3@frontier.com	N/A	Actions can be taken that are not easy, but not as devastating as breaching dams that give us recreation, power, flood control, commerce. How about stopping all commercial fishing on the rivers, and even in areas of the ocean, or at least place limits on their take.	Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the 2018 NOAA EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so.
4459	1	juan@dancingredband.com	N/A	The EIS must include a basin-wide review of flood risk management and how the 2024 expiration of the coordinated flood control operations under the U.S.-Canada Columbia River Treaty will impact storage and flows in the Columbia and Snake.	The Range of Alternatives Section (Section 2.4 of the CRSO EIS) provides a brief discussion of the Columbia River Treaty, why it is not included in the CRSO EIS, and when it would be added to this NEPA effort. As stated in the CRSO Draft EIS, the information about CRT-related operations available in 2016 is applied in the Draft EIS analysis as the best-available information. The CRSO Draft EIS evaluated the implications of the CRS alternatives using the Treaty coordinated operations, including their relationship to hydropower, ecosystem, and flood risk management, with the best available information. As is also noted in the Draft EIS, if CRT-related operations change after 2024 in a manner that presents new information or circumstances resulting in significant changes that were not previously addressed, those changes will be addressed by this NEPA process if they are identified in time or subsequently in another NEPA process, if necessary.
4459	2	juan@dancingredband.com	N/A	The EIS must consider the impacts of future irrigation withdrawals, from the lower Snake, which are likely to increase due to climate change.	Through ongoing regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives.
4459	3	juan@dancingredband.com	N/A	The EIS must include consideration of fish passage and reintroduction above Grand Coulee and Chief Joseph dams to support tribal fishery restoration goals in the Upper Columbia	Measures to reintroduce salmon above Chief Joseph Dam and Grand Coulee Dam were evaluated early in the process to develop alternatives but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps.
4459	4	juan@dancingredband.com	N/A	The EIS must consider the proper context for addressing the benefits and costs of the Columbia-Snake hydropower system, which means properly addressing the enormous costs - past, present, and future - to the tribes within the basin from the loss and eventual extinction of salmon and steelhead.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4. Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by resource.
4460	1	pmangarella44@gmail.com	N/A	One alternative that must be considered to be responsible and comply with NEPA regulations is dam removal and restoration, a strategy that has proven to be successful in numerous watersheds throughout the Unites States and is being considered for other important river systems (eg Klamath River in California and Oregon). Please be responsible and analyze in the DEIS this alternative and evaluate its potential efficacy relative to other alternatives.	The EIS studied breaching the four lower Snake River Dams as part of the MO3. Many dam removal projects that have occurred across the United States have very different circumstances than what is contemplated in MO3. Most other dam removal or breaching projects have been on dams that do not have fish passage, do not generate power or have very limited generation capacity, and have proximal and intact fish habitat. The lower Snake River dams have fish passage, an annual power production of approximately 1,000 aMW, and even with lower Snake River dam breach the Snake River would still have regulated flows due to the dams located upstream.
4472	1	skydive1955@yahoo.com	N/A	After talking with the the Washington Department of Fish and Wildlife concerning the success of fish population increases after the removal of dams on the west side of the state, the WDFW has said they are not even reviewing the effectiveness of the da renewal. They have no evidence the dam removal did anything to improve the fish return rates. Therefore, statements indicating dam removal would be an effective method for increasing fish return rates is not based on any facts gathered since the west side dam removal.	Modeling and analysis for the Draft EIS indicates that breaching would be beneficial to salmon and steelhead in the Snake River basin. However, the degree of that benefit is varies depending on modeling assumptions of the CSS and NOAA lifecycle models. The co-lead agencies primarily focused analysis on issues specific to Snake River dam removal, but did evaluate information from other areas such as Condit and Elwha Dams as mentioned in this comment.
4474	1	troutbumlg71-deis@yahoo.com	N/A	Dam removal is a proven method to restore fish populations as has been proven in Maine and the Olympic Peninsula of Washington State.	The EIS studied breaching the four lower Snake River dams as part of Multiple Objective alternative 3. Many dam removal projects that have occurred across the United States have very different circumstances than what is contemplated in MO3. The commenter is correct regarding Elwha Dam in Washington State, however, this example has little relevance to the four lower Snake River dams. Elwha Dam had no passage and did not provide economic benefits. In contrast, the four lower Snake River dams do have fish passage while also producing power, and providing navigation and recreation. The four lower Snake River dams would still have regulated flows due to the dams located upstream. The Preferred Alternative meets certain EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3 which includes breaching the four lower Snake River dams, by contrast, has significant regional economic and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend MO3 in the Draft EIS, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
4476	1	gb.pms83420@gmail.com	N/A	My main concern with the PA is increased spill of up to 125% total dissolved gas (TDG) levels, resulting in higher power costs and possibly adverse effects to ESA-listed species. I support higher spill levels and the resulting higher power costs only if scientific analyses clearly show a meaningful benefit to ESA-listed species.	The co-lead agencies used the high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
4482	1	scotthomson@me.com	N/A	I am against removal of the lower four dams on the Snake River. Of the 15 dams on the Snake these four are the only ones with fish passage. If dam removal is a preferred option we would be much better served by removing four of the eleven other dams that lack fish passage. There are other issues such as ocean conditions that need to be addressed before any dam removal is considered. The fish runs on other Nortwest rivers without dams have declined as well over the same time period of time. Yet we seem fixated on removing the lower four dams on the Snake.	The Draft EIS acknowledges and describes the many factors that affect salmon and steelhead, including the effects of ocean conditions. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service website at: https://www.nwfsc.noaa.gov/research/index.cfm. The agencies evaluated the management of the Federal projects and potential to improve conditions for ESA-listed species. The scope of the EIS is limited to analyzing the effects of operation, maintenance, and configuration of the Columbia River System projects under the jurisdiction of the co-lead agencies, which, in the Snake River, is limited to the four lower Snake River dams described in the Draft EIS. The breaching of these four dams was considered in Multiple Objective alternative 3, but not selected in the Preferred Alternative.
4484	1	Watershedfishbio@yahoo.com	N/A	Climate change will drastically and adversely affect water delivery timing, flood risk and late seasonal flow levels, temperatures, nutrients and forage, fish populations and wildlife habitats. In particular the EIS fails to evaluate the significant adverse effects of continued operation of Federal dams on the Columbia and Snake rivers in combination with the above highly foreseeable climate change impacts	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia Basin in still under development and was not available for us in this study. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, there are not reliable models at this time at the resolution required (river scale vs. global or regional scale). This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapter 4). Chapter 7 includes the climate effects to affected resources under the Preferred Alternative.
4484	2	Watershedfishbio@yahoo.com	N/A	In addition there would be significant recreational, economic and wetlands/wildlife benefits of dam breaching, which is a reasonable and viable alternative action which has not been included in the final set of alternatives.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative (PA) is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the PA also meets most other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The effects of breaching the four lower Snake River dams (a measure included in MO3) is discussed in Chapter 3, including recreation in Section 3.11.3.5, transportation and navigation (which includes some economic effects) in Section 3.10.3.5, and vegetation, wetlands, wildlife, and floodplains in Section 3.6.3.5, among other resources.
4488	1	N/A	N/A	It is a fact that barging is the most efficient and least carbon-intensive mode of cargo transportation. Barging is almost 40% more fuel-efficient than trains and 270% more fuel-efficient than semi-trucks. Barging on the Snake River along keeps nearly 150,000 trucks off of our highways each year. Tug boats and barges have operated on the Columbia and Snake River system for decades and have proven to be the safest, most efficient, and most environmentally-friendly mode of transportation. Removing dams would have a direct impact on that portion of our transportation industry and global supply chain, and secondary effects that would impact millions of people.	Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Northwest currently and removing that option would increase transportation costs for grain producers, as the EIS shows. Depending on the scenario, truck ton-miles may experience an increase of 19 percent (under Scenario 1, when rail rates are not assumed to increase) to 84 percent (when rail rates increase by 50 percent) under Multiple Objective alternative 3 when compared to the No Action Alternative. Rail ton-miles may increase by as much as 86 percent (under Scenario 1, when rail rates are not assumed to increase) or decrease by 2 percent (under Scenario 2, when rail rates increase by 50 percent). The EIS also found that truck trips could increase, ranging from an additional 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region.
4489	1	jpolehn@yahoo.com	N/A	2) Also, the dams provide the ability to use more of our land productively/efficiently. 3) The dams provide for stored water in times when water is not plentiful. The dams are also an emergency preparedness approach to preventing floods. Removal of them would weaken our infrastructure and our nation.	Thank you for your comment.
4493	1	N/A	N/A	These same organizations also claim that commodity barge shipping could be converted to train and truck. The magnitude of this suggestion is almost laughable if it werent so serious! There is no way Washingtons highway and rail system could handle the freight currently carried by barges. Even if it could, how could the highways and rails be maintained when the majority of state transportation tax dollars are spent in the Puget Sound area..not eastern Washington, and with the result of recent initiatives making transportation projects even more minimal.	The Navigation and Transportation Section 3.10 reflects the adverse effects of implementing MO3 including discussions of transportation mode capacity and cost of grain transport. The EIS explains in Section 3.10.3.5 that additional costs for investments in infrastructure would be required separate from the increases in transportation costs to farmers. There would need to be investments in infrastructure if dams are breached, both public and private sector investment in the absence of river navigation. Section 3.10 provides an evaluation of the Columbia Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, and low air emissions relative to other transportation modes. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear and tear costs may occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region.
4493	2	N/A	N/A	The environmental groups have also suggested converting farms back to dry land crops, such as wheat. They give no suggestion as to replacement of the hundreds of thousands of acres of orchards, vineyards, and vegetables that are produced in this region and the enormity of the trickle-down impact on the economy (especially family-wage jobs) from it.	Section 3.12.3.4 discusses the assumptions related to the loss of irrigated acreage under MO3. This section also discusses the Regional Economic Effects analysis which estimates how the decreased agricultural production would affect employment, labor income and output (sales) in this region. The Preferred Alternative is not expected to change the ability to deliver existing water supply because the changes in flow and reservoir elevations are expected to be negligible.
4494	1	katiestuart33@gmail.com	N/A	Please accept these comments, conclusions and recommendations in regard to the CRSO-DEIS for the Columbia River System Operations. Your website required me to review 270 megabytes (over 5,000 pages) of information from a website to understand the entire proposal. Yet the co-lead agencies have made it extremely difficult to almost impossible to file comments online or hand-deliver comments. The filing online is limited to a maximum of 100 kb with no more than 5 attachments of 2 megabytes apiece. I have substantively reduced my comments, including graphs and charts to meet the newly assigned filing requirement. During my career, I received thousands of comments and never set such limitiations. In addition, I have filed comments with many other federal agencies including the US Forest Service and US Bureau of Land Management and have never encountered such obstructive difficulties in filing comments. It prejudicial and possibly illegal NEPA to limit public comments in both manner and size limit. This is completely unacceptable and likely illegal for 3 public agencies to make filing a document so challenging and difficult	The co-lead agencies apologize for any technical difficulty experienced. It is accurate that the website had file size limitations that were listed for a single entry. That was not to limit you in your comments, but to alert you to either submit them in batches on the website, or mail them to the comment mailbox, or call the information line so we could assist you.
4494	2	katiestuart33@gmail.com	N/A	1. The Soaring Costs of the Hydro System Lower Snake River Dams are too costly in both environmental and dollar costs The Bonneville Power Administration (BPA) is the federal agency that markets the dams power output, and the intent was to turn cheap electricity into a comerstone of the regional economy. BPAs mission was realigned in 1980 under the Northwest Power Act to both maintain the reliability of power production and find the regional effort to recover wild salmon and steelhead. Currently, a third of the main-stem Columbia dam infrastructure has exceeded its design life, and shutdowns have pushed the systems reliability below the hydroelectric industry average. While much of the power is sold to public utilities under 20-year contracts, revenue to BPA has declined due to expanding wind, solar, and natural gas plants that have reduced energy prices in western markets. All the funds spent on restoring wild salmon and steelhead, including building and maintaining large fish hatcheries (intended to provide harvest or support wild fish restoration), barging juvenile salmon and steelhead, spilling water to support downstream juvenile migrations, improving juvenile bypass systems, and other programs, have failed to salvage declining salmon and steelhead runs. All of the Snake River salmon and steelhead runs are federally listed under the Endangered Species Act (ESA) as endangered or threatened and have been so for almost 30 years. Meanwhile, BPAs financial problems have increased as the agency has drawn from cash reserves and borrowed from private lenders and the U.S. Treasury with debt reaching $15 billion dollars. BPA has spent most of its reserves and faces large debt for required but unfunded retrofits and replacements to the turbines in the 4 lower Snake River dams.	Bonneville's revenues have not declined over time, but less of Bonneville's revenue requirement is covered by net secondary sales of surplus power due to an industry-wide decline in market prices for wholesale power, which has required rates to firm customers under long-term contracts to increase. In light of these competitive pressures, Bonneville developed both strategic and financial plans to ensure Bonneville's rates continue to be competitive. See Draft EIS, Section 3.7.2.5, pages 3-801-802 and Section 3.7.3.1, pages 3-842-843. Bonneville has instilled a renewed focus on cost management discipline, resulting in a cost reduction of $66 million per year for the current rate periods operating costs compared to the last rate periods operating costs. This resulted in an average 0% base rate increase for power customers at a time when the general economy was facing material inflationary pressure. Bonneville's cost management discipline, and revenue enhancing activities continue to maintain Bonneville's competitiveness relative to other load serving power producers. However, actions such as removing the low-cost four lower Snake River dams would result in substantial upward rate pressure for Bonneville customers, moving Bonneville's competitive power products to be less competitive in the marketplace. See Draft EIS, Section 3.7.3.5, Table 3-166. The financial reserves figures described in the comment are inaccurate. As of the end of 2019, Bonneville's collective financial reserves were $731 million, not $5 million. Bonneville implemented the Financial Reserves Policy (FRP) in its BP-18 rates, which added new tools to maintain Bonneville's financial health, including the FRP Surcharge, which adds revenue recovery above costs to rebuild Bonneville's financial reserves. The comment also suggests that with additional surplus energy and declining market prices on the wholesale power market, the region must also have a surplus of power for load service. However, the loss of load probability studies used in the EIS indicate that while the region has substantial amounts of energy on an interim basis due to renewable buildout supported by government legislation, there is a deficit of flexible and dispatchable resources needed to meet growing resource variability and ramping requirements associated with more extreme load shapes. And, the entire power and transmission rate analysis shows that building new resources to replace the lost flexibility is expensive (See Section 3.7 and particularly Section 3.7.3.5, Lower Snake River Full Replacement Used in Rate Sensitivity Analysis, beginning on page 3-905 in the Draft EIS). For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value of the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90 percent of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170, Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review (see Footnote 1 below), the Headwater/Lower Snake Asset Class (see Footnote 2 below) is forecast to have a 50-year levelized cost of generation (see Footnote 3 below) of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Similarly, the Northwest Power Act does not obligate the co-lead agencies to recover ESA-listed species or to ensure restoration of other fish and wildlife. Instead, the co-lead agencies fish and wildlife mitigation responsibilities under Northwest Power Act are more limited, primarily, managing and operating Federal Columbia River Power System (FCRPS) projects, which includes the CRS, to protect, mitigate, and enhance (as opposed to recover) fish and wildlife affected by such projects in a manner that provides equitable treatment with the projects other authorized purposes and consistent with the purposes of the Act and applicable laws. In addition, Bonneville has a specific responsibility to fund protection, mitigation, and enhancement of fish and wildlife to the extent affected by development and operation of FCRPS projects consistent with the Northwest Power and Conservation Councils (Council) fish and wildlife program, the Councils power plan, and the purposes of the Act, which includes assurance of an adequate, efficient, economical, and reliable power supply. Therefore, contrary to the comments broad assertion, the Northwest Power Act does not make Bonneville responsible for funding the regional effort to recover wild salmon and steelhead. Moreover, the comments suggestion that billions in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish). Footnotes: 1. The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2. In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3. Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric. Finally, Although the turbines at the four lower Snake River dams are between 41 and 50 years old and nearing their design lives, there are no plans for any immediate replacements. Investment decisions are driven by equipment condition, probability and consequence of failure and, as such, it is common for equipment to be in service well past its design life. For example, some turbine runners at McNary dam will be over 70 years old by the time the replacement project is complete. Long-term planning analyses that calculate the optimal economic time to replace equipment based on current and expected equipment condition, probability of failure and outage consequence, point to the late 2030s as the earliest replacement dates for major powertrain equipment at the four lower Snake River dams. Most turbine replacements are forecasted between the 2040s and 2060s which would put the turbines at the four lower Snake River dams at about the same age at replacement as McNary.
4494	3	katiestuart33@gmail.com	N/A	Since 2008 in response to revenue losses, BPA has drawn down its fiscal reserves from $917 million in 2007 to a fragile $5 million in 2017. BPAs historic revenue stream relied partly upon surplus energy sales. Yet, development of other energy sources in places such as California to which BPA previously sold surplus at a profit has rendered BPAs surplus power no longer in high demand. BPA is now obligated to sell the surplus power at negative prices. More specifically, the price of surplus power averaged about $60 per Megawatt hour (MWh) prior to 2009. Since 2009, the average price for surplus power has been about $22 per MWh. Revenue has consequently dropped dramatically as a result of drop in price. BPA began raising the price of power for its contracted users and over the last 8 years has increased prices by 30%.	Bonneville's financial reserves at the end of 2017 were $765.7 million, and most recently at the end of 2019, $773.1 million. The BP-20 rate case marked an important milestone in Bonneville's implementation of its Strategic Plan. The power rate increase was zero percent. BP-18s rate increase was below the rate of inflation. Over the last four years, Bonneville has fundamentally changed course due to principled cost management. The comment also notes the competitive rate-pressures facing Bonneville. As discussed in the Draft EIS, Sections 3.7.2.5, pages 3-801-802 and Section 3.7.3.1, pages 3-842-843, upward rate pressure is an important factor in the competitiveness of Bonneville's rates. The EIS describes the upward rate pressure caused by each of the Multiple Objective alternatives, the largest range of which is associated with Multiple Objective alternative 3, which includes the measure to breach the four lower Snake River dams. See Draft EIS, Section 3.7.3.5, Table 3-166.
4494	4	katiestuart33@gmail.com	N/A	Further large expenses are for rehabilitating and replacing aging turbines in the 4 lower Snake River dams. All of the turbines as of 2020 are 40-50 years old and the USACE has stated that the life of each turbine is 35-45 years, requiring replacement. If the same costs are expected as turbine rehabilitation at McNary Dam on the Columbia River is true at the lower Snake River dams, then the estimated cost of replacement of 21 lower Snake River dam turbines exceeds $1 billion dollars. Given that these dams provide little power in an energy surplus situation, the likelihood of replacement of these turbines is zilch. The co-leads use of the 4 lower Snake River dams energy production to rationalize allowing native salmon and steelhead to go extinct is a false justification to avoid a decision to not breach the lower Snake River dams. It is stunning to me that you would allow these two native species to extinct in light of the negligible value of the four obsolescent and failing lower Snake River dams.	Bonneville, the Corps and Reclamation develop long-term strategies and plans that identify the optimal time to replace equipment based on equipment condition, criticality and risk. Age, although a factor in equipment condition, is not the determining factor when equipment is replaced. Existing strategies place the earliest optimal turbine replacement date in the 2030s, with the majority of the remaining 21 turbines falling in the 2040s and 2050s. Additionally, it has not been determined if all 6 units at each plant will be replaced at those times. Replacement costs for turbine runners and components are expected to be closer to $600 million in 2020 dollars, if all turbines are replaced. Generators windings would likely be replaced at the same time, which would add another $200 million. The 50-year levelized cost of generation, which includes costs for these replacements, is expected to be $11 to $12 per MWh. With allocations for Bonneville overhead, including Fish and Wildlife, the 50-year fully loaded cost is expected to be $25 to $30 per MWh for these dams. This means that we expect these resources to remain competitive while considering forecast replacement needs. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Finally, While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. As described in Section 3.7.3.5 of the draft EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are among the most valuable projects in the FCRPS. Further, the seasonality of the power supply is important. The region often has surplus power in the spring when the weather is mild and flows are high. The LOLP analysis of Multiple Objective Alternative 3 showed that the region would have an annual risk of power shortages of around 14 percent stemming from shortages in the winter and summer. See Appendix J, Hydropower, Section 4.1.2.4 in the draft EIS. As suggested by the comment, the EIS does identify ways of replacing the power from these dams, and the resulting costs impose substantial upward pressure on regional power rates.
4494	5	katiestuart33@gmail.com	N/A	2. A Trivial Amount of Energy is Produced at the 4 Lower Snake River Dams The 4 lower Snake dams together produce an average of 3.3% of the annual Pacific Northwest power supply. Yet the regional power surplus including breaching of the lower Snake dams is approximately 13.7%. A review of the regional energy load is that under critical, average and high-water years, the projected surplus from load generation is 3 to 4 times the average lower Snake River production. Essentially, even if the 4 lower Snake dams are breached, even under critical low water conditions, the Pacific Northwest region has an energy surplus. The Northwest Power and Conservation Council (NWPCC) projects additional power resulting solely from efficiency gains in 2020 will be 1000 aMW, which is a little more than the average annual output of the 4 lower Snake dams in the last 5 years. The CRSO-DEIS Executive Summary claims that Significant quantities of replacement resources would have to be built to maintain regional power reliabilitythe region would face the likelihood of a loss of load event, e.g. a power blackout, nearly one in every seven years in MO3, (CRSO-DEIS, Executive Summary, page 25). These claims are specious because the generation from the 4 lower Snake River dams is relatively insignificant, there is a surplus energy supply, there are increasing alternative energy sources from wind and solar, there are increased energy efficiencies, and blackouts are unrelated to lower Snake River dam outputs.	While the regional power system does have surplus in some periods, most typically in the spring of high-water years, there are also periods when the region has very little or no surplus. For example during a winter cold snap, demand for power may reach its annual peak. During a heat wave in summer, river flows may be relatively low and several Federal and non-Federal hydropower projects are spilling water for juvenile fish passage. The EIS analysis for MO3, which includes breaching the four lower Snake River dams, indicates that there is roughly a 14 percent chance of energy shortages in any given year (without factoring in the retirement of additional coal plants). See Section 3.7.3.5 of the Draft EIS (specifically Table 3-165). Appendix J, Chapter 4 shows the seasonal variation of the loss-of-load events. As explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, MO3 would have a direct and substantial impact on the supply of Federal power to meet regional load requirements. Breaching the four lower Snake River dams would reduce energy to meet regional load requirements, and reduce generating capacity (peaking capacity) to meet variability in loads. The four lower Snake River dams are among the most valuable projects in Federal Columbia River Power System. These dams provide over 1,000 MW of carbon-free energy and up to 2,000 MW of sustained peaking capacity at certain times of the year. The dams also have unparalleled ramping capability, the ability to quickly generate energy to match spikes in energy usage, with over 2,000 to approximately 2,300 MW of capability in certain months of the year (see Table 3-160 in the draft EIS). To maintain regional reliability at the No Action Alternative levels, replacement resources would be needed under MO3. The cost of replacing the capability of the four lower Snake River dams is described in detail in the Draft EIS in Section 3.7.3.5, Potential Replacement Resources and Associated Costs. The EIS takes into account the cost savings from the breaching of the four lower Snake River dams. Even with these savings, base rates paid by customers of Bonneville (local public and community owned utilities) would likely increase. Using natural gas as the replacement resource (the least-cost resource portfolio) Bonneville's wholesale power rates could increase between 4 and 10 percent. Using zero-carbon resources to replace lost capacity under MO3, Bonneville's wholesale power rate could increase between 13 percent to 50 percent. See Draft EIS, section 3.7.3.5, Table 3-166.
4494	6	katiestuart33@gmail.com	N/A	More specifically, the Pacific Northwest wind power plants produce nearly three times the combined generation of the 4 lower Snake dams. Montana has new wind power projects which are predicted to produce up to 5000 aMW by 2030 and are targeted for export to the Pacific West Coast states. Additional projects in Oregon such as the Wheatridge project will include 292 turbines with a peak capacity of 500 aMW and proposes wind, solar and battery backup to offer firm power. California once was a major buyer of BPAs surplus power and is adding an 14,000+ aMW of new solar energy to its own energy portfolio between 2018 and 2023. With the addition of wind and solar energy and other states producing more power and importing less BPA surplus power, the value of the 4 lower Snake River dams for generation is fictitious. These dams cost more to produce and maintain power than the value of the power for sales. Taxpayers and ratepayers are paying for obsolete dams that the co-lead agencies falsely claim are necessary. The co-lead agencies use of the 4 lower Snake River dams energy production to rationalize allowing native salmon and steelhead to go extinct is another false justification to avoid a decision to not breach the lower Snake River dams.	While the comment is accurate that additional renewable power development is occurring across the region, the EIS findings are not consistent with the comments conclusion that the four lower Snake River dams are unnecessary with the influx of new solar and wind. As discussed in Section 3.7.2.2, Power System Flexibility and Reliability, system reliability is maintained by relying on generating capacity that is dispatchable, meaning it is able to change on demand to meet fluctuations in supply and demand. Solar and wind resources are generally not dispatchable because their output is dependent on the availability of wind or sunshine. Hydropower and natural gas are dispatchable because they can adjust production within minutes or seconds. A resource that is capable of producing power, but is unable to because of a lack of wind or sun, cannot be relied upon in the same way as a dispatchable resource, that can be called upon to deliver firm energy when requested. The EIS describes how this dispatchability is essential to providing balancing reserves, which is used to meet system uncertainty and to integrate renewable resources, such as wind and solar. See Draft EIS, Section 3.7.2.2, Meeting System Uncertainty with Generation Balancing Reserves, Dispatchable Resources, and Ramping Capability. As explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are connected to Automatic Generating Control (AGC), making them among the few projects that are capable of providing balancing reserves. See Draft EIS, Section 3.7.3.5, Value of Lower Snake River Dam Ramping Capability. The four lower Snake River dams currently carry approximately 20 percent of upward flexibility and 8 percent of the downward flexibility held by the Federal Columbia River Power System (FCRPS) for balancing reserves. Replacing hydropower with solar and wind does not replace the dispatchable characteristics of the four lower Snake River dams. Indeed, the EIS found that the demand for the dispatchable capability of the four lower Snake River dams would increase as the need for balancing reserves grows to integrate additional wind and solar in the region. See Draft EIS, Section 3.7.3.5, Integration Services, page 3-832.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The comment is also incorrect in suggesting that the four lower Snake River dams' power is unnecessary for regional power needs. Bonneville sells power from the FCRPS as a unified system, not from specific projects. In this regard, the power generated from the four lower Snake River dams are pooled with all other FCRPS power sold by Bonneville to meet Bonneville's collective power obligations. Most of this power is used to meet the loads of regional publicly owned utilities, such as municipalities, rural utilities, and public utility districts under long-term power-sales contracts (see Draft EIS Section 3.7.2.5 Bonneville Power and Transmission Customers). A small portion of power is sold in the California energy market when there is surplus, but these sales are not from specific projects, but rather from the collective FCRPS. As explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, breaching the four lower Snake River dams would have a direct and substantial impact on the supply of Federal power to meet regional load requirements. These impacts would impact both actual energy to meet regional load requirements and generating capacity (peaking capacity) to meet variability in loads. The four lower Snake River dams are among the most valuable projects in FCRPS. These dams provide approximately 1,000 aMW of carbon-free energy on average and 2,000 MW of sustained peaking capacity at certain times of the year. See draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. The dams also provide important ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907 and Table 3-160.While the increase in solar and wind generation is consistent with the Draft EIS discussion in Section 3.7.2.1 Power Generation, the EIS still finds that the regional power system requires replacement power resources to maintain reliability under MO3. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170 in the Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review (see Footnote 1 below), the Headwater/Lower Snake Asset Class (see Footnote 2 below) is forecast to have a 50-year levelized cost of generation (see Footnote 3 below) of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. Footnotes: 1. The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2. In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3. Levelized Cost of Generation is defined as the forecast direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
4494	7	katiestuart33@gmail.com	N/A	3. The River Transportation is an Outdated and Unnecessary Transport System The east-west freight using the Columbia and Snake river transportation system has declined dramatically in the past two decades. Container freight movement from the Port of Lewiston has dropped to zero since 2000. In addition, the transport of wheat has steadily dropped since 1995. All wheat at Lewiston is now shipped via a private corporation at its own docks and total lower Snake River freight volume has dropped 40% since 2000. Paper, pulp, petroleum, logs and lumber are no longer shipped on the lower Snake River while increasing numbers of grain growers have shifted to rail transport. All river transport to Lewiston could be changed in a one-time cost to rail transport, notably of which many exporters have already done so. The co-lead agencies use of lower Snake River for freight transportation is disingenuous, costly, and unethical and is another false justification to avoid a decision not to breach the lower Snake River dams.	The commenter is correct that currently there is no containerized cargo shipping out of Snake River ports. The EIS recognizes in Section 3.10.1 that the container freight that previously moved through the Port of Portland recently shifted to the Ports of Tacoma and Seattle, Washington. In January 2020, weekly container service resumed at the Port of Portland. While no service to the Snake River is currently anticipated, the potential exists for future expansion of this service. Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Pacific Northwest currently and removing that option would increase transportation costs for grain producers, as the EIS shows. It is true that barge movements on the Snake/Columbia river have declined somewhat over the past 20 years. The EIS acknowledges that the decline is mostly attributed to investments in shuttle rail terminals. However, the EIS also acknowledges that shifting traffic to road and rail would increase costs to shippers and would require substantial infrastructure investments.
4494	8	katiestuart33@gmail.com	N/A	4. There are False Claims of Benefits for Flood Control and Irrigation The U.S. Congress authorized the USACE and Bureau of Reclamation to construct, operate, and maintain the system projects to meet multiple specified purposes, including flood control. The Executive Summary asserts that the Preferred Alternative ensures that human life and safety can be protected through flood risk management (CRSO-DEIS Executive Summary, page 32). However, the 4 lower Snake dams are not flood control dams but are run-of-the-river dams with little reservoir space for fluctuating water levels and with virtually no storage capacity. Essentially, the 4 dams do nothing to control flood risk in downstream reaches but conversely the dams create flood risk in Lewiston, Idaho and Clarkston, Washington. The reservoir created by Lower Granite Dam backs up water 40 miles to Lewiston and Clarkston, which are at the confluence of the Snake and Clearwater rivers. Large levees have been built there to prevent overflooding from the Lower Granite Dam reservoir which has sediment buildup, which typically occurs at the inflow of reservoirs. The accumulation of sediment at Lewiston and Clarkston is a continuous and costly problem that creates flood risk for these communities. Breaching of the 4 lower Snake Dams would eliminate sediment buildup, reduce flood risk, make the communities at Lewiston-Clarkston safer from flooding, and eliminate the high costs of continuously needed sediment dredging. The co-lead agencies use of the argument of flood control and safety for selecting the Preferred Alternative and avoiding the breaching of the 4 lower Snake River dams is fabrication to support a flawed conclusion. Breaching of the 4 lower Snake River dams would have no effect on flood control for river reaches downstream of the dams because they are run-of-river dams. Breaching the dams would reduce the risk of flooding that occurs in Lewiston and Clarkston. Therefore, breaching the 4 lower Snake River dams would save Snake River salmon and steelhead while eliminating risk from floods and increasing community safety.	The commenter is correct that the measure to breach the four lower Snake River dams in MO3 would eliminate sediment buildup and reduce flood risk at the confluence area of the Snake and Clearwater rivers (clarifying information has been added to Appendix K.1.7.3.). However, in general the four lower Snake River dams are not authorized for flood risk management, and there is no elevated risk to flooding in the lower Snake River reach for any of the EIS alternatives. Furthermore, the Corps Walla Walla District constructed eight miles of levees around Lewiston as mitigation to help protect lives and property from potentially destructive high-water conditions after the dams were built. Unlike freely flowing channels, in Lower Granite Reservoir the forebay elevation at the dam controls the energy grade-line of the water surface, and the reservoir is drawn down during high water events to ensure water levels remain low. The most recent dredging in the Lewiston area, has been to maintain a 14-foot depth in the navigation channel, as discussed in the 2014 Programmatic Sediment Management Plan (PSMP). Dredging outside of the navigation channel limits to maintain conveyance capacity has not been conducted since 1992. Provisional analyses described in the PSMP (Chapters 10-12) indicate that some segments of the channel in the upper reach of Lower Granite Reservoir are tending towards a state of relative morphological equilibrium under the prevailing sediment loads and discharges. Under the current flood control operations of Lower Granite Dam, during large flood flows, fluvial sediment transport processes were predicted to form an approximate equilibrium channel that maintains the conveyance capacity of the upper reach of Lower Granite Reservoir. During equilibrium sediment transport, the hydraulic conditions are great enough that sediment erosion balances sediment deposition so that there is no net change in the equilibrium depth of the channel segment. At even higher velocities, if sediment loading remains constant, the rate of sediment erosion will exceed deposition and a channel section will tend to erode to reestablish a new deeper equilibrium depth. Sediment eroded from the confluence area was predicted to transport into the deeper reservoir reach downstream of Silcott Island where it has less effect on the flood stage at the Lewiston levees. The co-lead agencies are legally obligated to operate and maintain the Columbia River System to meet multiple statutory purposes. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. Of the alternatives studied, the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
4494	9	katiestuart33@gmail.com	N/A	The CRSO-DEIS Executive Summary (page 24) states, breaching the dams would not allow the co-lead agencies to operate and maintain the dams for their congressionally authorized purposes of navigation, hydropower, envisioned recreational benefits, and water supply for irrigation purposes. The needs of fewer than two dozen irrigators which are all located on the Ice Harbor Reservoir are touted as one of the many reasons to maintain the 4 lower Snake River dams. For unknown reasons, the co-lead agencies assume that if the dams are breached, that 47,926 acres would no longer be irrigated at a social welfare and public taxpayer cost of $458 million. That assumption is false on the face of it, since the river itself would remain available for irrigation. A one-time expense of aid to farmers to upgrade pumps and lengthen water lines would ensure much of the 47,926 acres are irrigated post-breaching. Further the CRSO-DEIS fails to acknowledge the importance of restoring fall Chinook spawning habitat and 15,000 acres of prime riverine habitat and agricultural land that is inundated by the lower Snake River dams.	This EIS discusses engineering solutions including pipeline extensions, in Section 3.12.3. MO3, Region C discussion begins on page 3-1267 line 3244 and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which concluded that modifying the existing pump system was cost prohibitive. Section 3.5.3.6 under the Larval Development/Juvenile rearing sub-heading (line 17110) of the Draft EIS describes that breaching the four lower Snake River dams is estimated to increase the available spawning habitat for fall-run Chinook from 226 acres to 3,521 acres, an increase of 15 times the area available today. Shallow water rearing habitat is very important to juvenile fall Chinook. The Final EIS has been updated to more clearly articulate this.
4494	10	katiestuart33@gmail.com	N/A	5. Saving Snake River Salmon and Steelhead Must Be a Top Priority to save the species from extinction and meet the Order from the U.S. District Court The Columbia-Snake River Watershed was once one of the top salmon-producing ecosystems in the world. Nearly 50% of the Columbia Rivers renowned historic runs of wild salmon and steelhead were from the Snake River and its tributaries. Since the completion of the 4 lower Snake River dams in the 1970s, wild Snake River salmon and steelhead have been on a steady decline toward extinction, despite spawning and rearing in rivers of central Idaho which have some of the best habitat in the lower 48 states. The 2019 returns of adult fish were near record lows for steelhead, sockeye and Chinook salmon and are near extinction. The Snake River dams have altered flow regimes, temperature, oxygen and sediment dynamics, and channel geomorphology, and inundated 140 miles of the lower Snake River, much of which was fall Chinook spawning habitat. The Columbia and Snake rivers were changed from free-flowing rivers to a series of dams, with slow moving reservoirs that delay downstream migrating juveniles. The reservoir pools become too hot for migratory salmon and steelhead and have abundant predators such as northern pikeminnow and smallmouth bass.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
4494	11	katiestuart33@gmail.com	N/A	The Snake River, where anadromous fish species once measured in the hundreds of thousands or millions, is now home to declining populations of four ESA-listed species of anadromous fish: spring/summer Chinook, fall Chinook, sockeye and steelhead. Returning wild fish estimates are concealed by large numbers of hatchery-produced fish. Hatchery fish were intended as a temporary mitigation for producing harvestable fish due to anticipated losses from the construction of the dams and reservoirs. However, native wild runs remain at precariously low levels, and continue to decline.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Diversity is an important factor in an ESU's ability to persist and adapt, and is one of the factors considered in assessing an ESU's long term viability, along with abundance, productivity, and spatial structure. All these factors would be necessary for an ESA recovery analysis. The co-lead agencies have continuing hatchery obligations.
4494	12	katiestuart33@gmail.com	N/A	ish Passage - Upstream and downstream fish passage is one of the greatest impacts of the four lower Snake River dams despite having fish ladders for upstream migration and juvenile bypass systems for downstream migrating juveniles. Fish from the Snake River must navigate a cumulative of eight large dams on the Columbia and Snake river for upstream and downstream migration. For adults, typically 10-20% are lost on their upstream journey to	The co-lead agencies have incorporated extensive improvements to structures and operations to mitigate for the effects of run of river dams on the Snake and Columbia rivers. Fish ladders have been shown to be effective in passing upstream high numbers of adult salmon and steelhead, while spill and barging operations have improved downstream survival and passage.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the Snake River, traveling through warm slack water reservoirs and are subject to disease, predators, and fallbacks in fish ladders. The journey for young migrating fish from the Snake River historically took a few days to a week and can now take up to 3-4 weeks traveling through multiple dams and reservoirs. Downstream migrating juvenile losses are much higher than upstream migrating adults. Direct or delayed mortality results from passage through each dam and is due to severe changes in hydraulics, turbulence and turbine blades which cause death and injury from strike, shear, pressure gradients, and disorientation. After passing through each dam, juvenile fish are also more susceptible to predation. Additional losses are from swimming downstream through each reservoir. Rather than drifting with downstream currents of a large river, they are subject to additional mortality at each reservoir from expending energy to swim downstream, predators, and cumulative stresses. Further delayed mortality occurs below each dam from the cumulative effects of experiencing the hydro system.	
4494	13	katiestuart33@gmail.com	N/A	The co-lead agencies superficially claim a per-dam survival rate of approximately 95% (CRSO-DEIS Executive Summary, Figure ES-4, page 19 and Chapter 3, Figure 3-113, page 3-302). However, the claim fails to account for cumulative losses at all projects which are not additive but multiplicative. Studies have demonstrated that cumulative losses approach 50% for downstream migrating juveniles from Lower Granite Dam to the tailrace below Bonneville Dam, while delayed mortality below the hydro system causes additional mortality. Upon reaching the Columbia River estuary and Pacific Ocean, survival rates for juveniles from Lower Granite Dam to the ocean are typically less than 20%.	These estimates are put in context in the Draft EIS on page 301: "To aid the downstream passage of juvenile salmon and steelhead, the co-lead agencies have worked to improve passage and survival past the dams and through the reservoirs of the CRS. Figure 3-112, shows recent estimates of survival at the eight lower CRS projects with fish passage. The dam survival estimates do not include systemwide or latent effects (see section 3.5.3.1). These estimates were developed [to] show progress towards meeting the individual dam survival goals developed during the 2008 Biological Opinion of 96 percent survival past each dam for yearling Chinook and steelhead, and 93 percent for Snake River sub-yearling fall Chinook." Later in this section (referenced in the quotations above) the analysis discusses system survival rates, as well as latent mortality. The analysis of alternatives presented in-river system survival, which reflects the commenter's "cumulative losses," and Smolt-to-Adult return rates (SARs), for those populations which could be modeled, among other metrics. The per-dam survival metric is both accurate and useful in measuring changes in near field survival at the dams due to structural modifications (e.g. surface passage routes) or operation changes (changes to spill levels or spill patterns). The per-dam survival estimates are multiplicative in nature and the improvements in at-dam survival over the past ten years have been shown to contribute to improvements in total in-river survival of smolts migrating through the CRS especially for steelhead. These figures were used to provide context in the affected environment section. The focus of this EIS and the analysis presented throughout this EIS in Sections 3.5 and 7.7.4 hinge around total in-river survival, travel time, powerhouse passage rates, and SARs. Based on the EIS analysis of fish in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. With respect to the Preferred Alternative, the CSS model predicts that average SARs will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. These improvements are expected to benefit all of the stocks listed in this comment if latent mortality is reduced through higher spill levels.
4494	14	katiestuart33@gmail.com	N/A	Smolt-to-adult ratios (SARs) are the best benchmark for measuring survival since these ratios measure survival from the downstream migrating juvenile to the returning adult. A SAR of 2-6% is needed to assure the survival of a fish species and these SARs are the regional recovery goals of the Northwest Power and Conservation Council. However, Snake River fish typically have SARs less than 1-2%, hence the continued downward spiral to extinction. Anadromous fish that pass through fewer hydroelectric dams on the Columbia River system have higher SARs and higher levels of survival (Figures 2 and 3). With cumulative impacts of direct and delayed mortality from the hydro system from the Snake River to the Pacific Ocean, it is crystal clear that salmon and steelhead cannot meet regional 2-6% SAR goals. Like the Snake River wild Coho that went extinct in the mid-1980s, Chinook, sockeye and steelhead are doomed to extinction unless a combination of dam breaching of the 4 lower Snake River dams, and the highest spill levels of 125% Total Dissolved Gas (TDG) at the remaining dams on the Columbia mainstem river are implemented.	The 2 to 6 percent Smolt-to-Adult return rates (SARs) target referenced in this comment refers to the Northwest Power and Conservation Councils (Council's) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia River Basin, the Councils recovery goals are shared by many parties. Based on the analysis, the Preferred Alternative will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies used high quality information in the EIS analysis. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average SARs will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of the Council's recovery targets for the region) increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. In relation to the comment that fish passing few dams have higher SARs and survival, the co-lead agencies follow the guidance from the Independent Science Advisory Board, and do not typically weigh performance of one population vs. another. It is difficult to isolate causative factors in those types of comparisons.
4494	15	katiestuart33@gmail.com	N/A	Water Temperatures Another way that the hydro system dams cause impacts to migratory fish is the cumulative effects of high-water temperatures caused by Snake River and Columbia main stem dams and associated reservoirs. Stagnant reservoirs in combination with increasingly hot temperatures due to climate change are lethal to migrating fish like salmon and steelhead. A water temperature above 680F delays upstream migrating adults, depletes energy reserves, increases respiration, and increases disease ultimately causing direct or delayed mortality. In the hot, dry summer of 2015, a harbinger of future summers in the Pacific Northwest, over 95% of returning Snake River sockeye salmon run died prematurely in the Columbia and Lower Snake rivers, most of them never making it to the Snake River.	The EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives' effects on Snake River stocks, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Regarding climate change, the climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at this time at the resolution required (river scale vs. global or regional scale). Therefore it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Sections 4.2.3 and 7.8). Regarding water temperatures under Multiple Objective alternative 3, which includes breaching the four lower Snake River dams, analysis indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action Alternative conditions in the Snake River. However, even with the four lower Snake River dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The models showed minor changes in the Columbia River under this alternative.
4494	16	katiestuart33@gmail.com	N/A	A study done by Schultz and Johnson in 2017 used an U.S. Environmental Protection Agency (EPA) model and validated work by the EPA that showed a free-flowing Lower Snake River would have remained cooler than 68F during most of the hot summer of 2015. The analyses by Schultz and Johnson demonstrated that in dammed reaches of the lower Snake River, especially the three downstream reservoirs, water temperature reached 68F in mid to late June and remained near or above 68F until September.	The Draft EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives' effects on salmon and steelhead, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Water temperatures under MO3, which includes breaching the four lower Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions in the Snake River. However, even with the four lower Snake River dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The models showed minor changes in the Columbia River under this alternative. Regarding predicted water temperatures under MO3, as compared to the results documented by Schultz and Johnson (2017) and derived from past EPA analysis, there are a few key differences between these efforts that should be made clear. First, the RBM-10 (TMDL) model predicts a daily average water temperature, while the CE-QUAL W2/HEC-RAS (EIS) model predicts a daily maximum value. The co-lead agencies chose the daily maximum water temperature metric since most water quality standards are based on this metric. Second, the RBM-10 model uses weather data from airport weather stations with the longest records, whereas the co-lead agencies used weather stations with the most spatial coverage and spatial representation (airport and AgriMet weather stations). Lastly, RBM-10 was utilized for a free-flowing scenario. The free-flowing scenario includes the absence of Grand Coulee, Chief Joseph, the five mid-Columbia PUD dams, the lower four Columbia River and the lower four Snake River dams. However, this "free-flowing" scenario retains Dworshak Dam as a boundary condition and uses observed flows and temperatures. 2010 channel bathymetry is utilized throughout system. The TMDL assessment focused on quantifying the thermal load of the dams by comparing existing conditions to a free-flowing scenario. The co-lead agencies used HEC-RAS (1-dimensional model) for the MO3 alternative for the lower Snake River; CE-QUAL W2 (2-dimensional model) was used for the other mainstem CRS dams. MO3 includes removing the earthen embankments, abutments and portions of existing structures at the dams to eliminate reservoirs. For MO3 all other CRS dams remain in place, and Dworshak Dam uses the same operations, both modeled flows and temperature, from the No Action Alternative. For the lower Snake River 1934 (pre-dam) channel bathymetry was utilized; 2010 geometry was used elsewhere in the system. Given the differences between the analysis in the Draft EIS and the 2017 study, direct comparisons between the two assessments are not appropriate. Both models have been reviewed extensively by the co-lead agencies. EPA concluded that both temperature models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As stated in EPA's review letter (#16-0059), EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models were appropriate to use in developing the Draft EIS.
4494	17	katiestuart33@gmail.com	N/A	Essentially, as water moves slowly downstream through the four lower Snake River dams and associated reservoirs, each reservoir increases water temperature by about 2 degrees F. The free-flowing simulation showed no significant and long term rising temperatures, and that without the dams, water temperatures in the lower Snake River would warm a relatively minor amount as it flowed to the Columbia River. Despite perilously hot air temperatures and low flows that occurred in 2015, the lower Snake River would have been cool enough for salmon and steelhead if the dams had not been present. While there would have been minor increases in temperatures, they would have been short lived. With the existing 8 dam complex that fish navigate from the Snake River to below Bonneville, Dam, and climate change intensifying the impacts of high temperatures and low flows, Snake River fish are at risk of extinction. High water temperatures above 68F are now common for lengthy periods in July, August, and September. The only way to ensure survival and avoid extinction of Snake River anadromous fish is to have a free-flowing lower Snake River.	The EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives' effects on salmon and steelhead, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Water temperatures under MO3, which includes breaching the four lower Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action Alternative conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The models showed minor changes in the Columbia River under this alternative. The co-lead agencies used HEC-RAS (1-dimensional model) for MO3 for the lower Snake River; CE-QUAL W2 (2-dimensional model) was used for the other mainstem CRS dams. MO3 includes removing the earthen embankments, abutments and portions of existing structures at the dams to eliminate the reservoirs. For MO3 all other CRS dams remain in place, and Dworshak Dam uses the same operations, both modeled flows and temperature, from the No Action Alternative. For the lower Snake River 1934 (pre-dam) channel bathymetry was utilized throughout lower Snake River; 2010 geometry was used elsewhere in the system. The EIS assessment focused on predicting water temperature and Total Dissolved Gas (TDG) conditions under the MO3 alternative, which included a measure for breaching all four lower Snake River dams. The models used in the Draft EIS have been reviewed extensively by experts including the EPA, USGS and Portland State University. As stated in EPA's review letter (#16-0059), EPA agrees with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS.
4494	18	katiestuart33@gmail.com	N/A	Alternatives The co-lead agencies peddle the Flex Spill Agreement in the CRSO-DEIS as the basis for the Preferred Alternative and conclude that small adjustments in spill and other mechanistic fixes in the hydro system will improve survival of anadromous fish while retaining all the falsely claimed benefits of the four lower Snake River dams energy, water transport of freight, flood control and irrigation. The Flex Spill Agreement was a process and intended to avoid litigation during the time that the CRSO-DEIS was developed. The Preferred Alternative is a version of the Flex Spill agreement with modifications that benefit power generation revenue and irrigation. There are no improvements for Snake River salmon and steelhead populations included in this alternative. It does not include operations for the long term, and only addresses operations for the last year of the Flex Spill Agreement in 2021. While co-lead agencies make references in the Preferred Alternative to an indeterminate and open-ended adaptive management process, there is no guarantee nor likelihood that the regional 4% average SAR goal will be met. Indeed, the Preferred Alternative includes measures that will cause additional harm to salmon and steelhead populations, such as additional irrigation water withdrawals from the Columbia River of 1.254 million acre-	The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. In the EIS analysis of effects, the co-lead agencies used high quality information, including models and studies published in peer-reviewed scientific journals. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The CSS model, which includes latent mortality effects predicts that median Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. While meeting the regional SARs goal of 4 percent is a worthwhile endeavor, it is a recovery goal. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				feet. While the Preferred Alternative claims to be a balanced approach, it is obviously a continuation of status quo management which has caused salmon and steelhead to reach the brink of extinction.	The commenter's suggestion that the flex spill operation is only planned for one year is not an accurate interpretation of the Preferred Alternative. If no adaptive management needs are identified, the operation would continue until modified by the co-lead agencies. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Three of the four Multiple Objective alternatives contemplate an additional water supply withdrawal of 1.254 million acre-feet at Hungry Horse, Grand Coulee, and the Chief Joseph Dam project. The Preferred Alternative included an additional 45,000 acre-feet of water withdrawal above the No Action due to the uncertainty over the timing and extent of the development of new water supply projects for the full volume.
4494	19	katiestuart33@gmail.com	N/A	A careful review of the Flex Spill in 2019 showed that downstream survival, from juvenile fish powerhouse encounters, and delayed water transit time was equal to or worse than the 2018 Biological Opinion spill flows. The Flex Spill agreement states that fish passage must be better or at least no worse than what would have occurred under the 2018 court ordered injunctive spill order. However, in 2019 juvenile fish passage through powerhouses was worse than the injunctive spill order and more fish went through powerhouses than would have occurred under the court ordered spill.	One year of in-river migration data is not adequate to assess the effects of the flex spill operation. The modeled benefits of this operation are based on multiple years of data, and will require Smolt-to-adult returns rates (SARs) to evaluate. The starting point for the Preferred Alternative is spill to the 125 percent Total Dissolved Gas (TDG) cap, so it will involve more spill than 2019 Flex Spill. After careful review of monitoring data from the 2019 flex spill operation, the flex spill signatory entities agreed that all biological, hydropower generation, and operational aspects of 2019 met all parties expectations. It is difficult, and not advisable to take a single year of data from an operation, such as the single year of 2019, and make long-term and long-range decisions based on a limited operation. That is why the parties to the agreement based their expected outcomes on multiple water conditions and potential outcomes. When considering benefits to fish, the flex spill parties used powerhouse encounter rate or PITPH as the primary metric, not in-river survival or even SARs due to the variation in those metrics and the limited opportunity to evaluate and monitor based on a single year of data.
4494	20	katiestuart33@gmail.com	N/A	Spill to the higher 125% TDG level was only provided at 4 of the 8 Columbia/Snake hydroelectric projects. For example, Bonneville, The Dalles, and John Day dams spill were capped at 120% TDG. All of the projects reduced spill for 8 of the 24-hour day cycle which decreased fish protection at these projects during those 8 hours of reduced spill. The Columbia/Snake hydropower system cannot meet the alleged purpose of the Flex Spill agreement because spill is a net reduction at the downriver projects. Therefore, Oregon and Washington fish stocks from the John Day, Deschutes and Yakima rivers had increased mortality and decreased survival from increased powerhouse encounters.	For 2019, the 2019-2021 Spill Operation Agreement involved spill to the 120 percent Total Dissolved Gas (TDG) cap. 2020 will be the first year of spill to 125% TDG under the 2019-2021 Spill Operation Agreement. Table 7.3 in the Draft EIS details the Preferred Alternative's spring fish passage spill for each project. Spill for 16 hours to the 125 percent TDG is prescribed for 6 of the 8 lower Snake and Columbia River dams, including Bonneville and McNary dams on the lower Columbia River.
4494	21	katiestuart33@gmail.com	N/A	The Fish Passage Center sent a memo to the co-lead agencies on January 24, 2020 that plainly showed that the Preferred Alternative is a high risk alternative for Snake River salmon and steelhead . In the lower quartile data range, low SARs and continued population decline (<1% SARs) are predicted to occur a majority of the time and even more can expected with warming and drying climate conditions. The Preferred Alternative makes no changes to restore Snake River salmon and steelhead. The ambiguous reference to adaptive management processes continues the status quo and fails to restore Snake River anadromous fish. This CRSO-DEIS fails to meet the purpose and need to evaluate how to insure that the prospective management of the System is not likely to jeopardize the continued existence of any endangered species or threatened species or result in the destruction or adverse modification of designated critical habitat (CRSO-DEIS, Executive Summary, page 16). The only option for recovery and avoiding extinction of Snake River salmon and steelhead is to breach the 4 lower Snake River dams (Alternative MO3) and spill to the 125% tailrace TDG gas cap (Alternative MO4) at remaining projects, 24 hours per day. Until the dams are breached, spilling to 125% at all dams is only an interim measure to keep these fish on life support. The combined MO3 and MO4 show the greatest improvements and the only path to successfully restore anadromous fish from the Snake River. These combined alternatives have the highest probability of meeting the 4% average SAR regional goal. Even the lower end of the predicted SAR range for MO3 was also above 1% for both Chinook and steelhead. The remaining alternatives (No Action, MO1, MO2, and the Preferred Alternative) fail to meet the regional 4% SAR goal, and the lower end of the predicted SAR ranges are well below 1%, indicating a high probability of extinction.	The 4 percent Smolt-to-Adult return rate (SAR) target referenced in this comment refers to the Northwest Power and Conservation Councils (Council's) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia River Basin, the Councils recovery goals are shared by many parties. Based on the EIS analysis, the Preferred Alternative will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies used current, high quality information in the EIS analysis. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average SARs will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of the Council's recovery targets for the region) increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Improving anadromous fish conditions were two of the eight objectives of the EIS. The agencies disagree, however, that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125 percent Total Dissolved Gas (TDG) at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For power and transmission, MO3 and Multiple Objective alternative 4 (MO4), individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5 percent of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
4494	22	katiestuart33@gmail.com	N/A	Further, the CRSO-DEIS proposes an alternative that continues decades of failed status quo management to the detriment of Snake River anadromous fish. Current SARs for Snake River fish are less than 1%, which means their populations are steadily dwindling and will continue to decline. Even worse, the Preferred Alternative includes actions that are likely to accelerate extinction of these fish such as additional appropriation of 1.254 million acre-feet of irrigation water further depleting flows for juvenile migration.	The Preferred Alternative is not simply a continuation of the status quo. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on the analysis, the co-lead agencies anticipate that the Preferred Alternative would provide benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The CSS model, which includes latent mortality effects, predicts that median Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. In three of the Multiple Objective alternatives a measure for additional water supply withdrawal from Lake Roosevelt of 1.15maf (approximately 1,150,000 acre-feet) was contemplated. This withdrawal directly reduces flows in the river, but these flow decreases associated with this additional water supply were on the order of 1 to 2 percent of total flows, see Section 3.2 for more information. In the Preferred Alternative, the additional water supply was substantially reduced to an additional 45,000 acre-feet. The impacts from this additional water supply is smaller than 1 percent of outflows from Grand Coulee.
4500	1	N/A	N/A	I would like to begin my comment with a Governmental report from 1949 regarding the proposed building of the Snake River dams: Another serious threat to the Columbia River fishery is the proposed construction by the US Army Engineers of Ice Harbor and three other dams on the lower Snake River between Pasco, WA and Lewiston, ID to provide slackwater navigation and a relatively minor block of power. The development would remove part of the cost of waterborne shipping from the shipper and place it on the taxpayer, jeopardizing more than of the Columbia River salmon production in exchange for 148 miles of subsidized barging route. The transportation saving to the shipper would amount to $2,000,000 annually, while salmon runs having a wholesale value of about $9,000,000 would be threatened with destruction. We knew over 70 years ago the destruction that these dams would pose to our environment, and it has turned out just as predicted. We taxpayers are subsidizing barging of wheat for a handful of farmers while we watch in horror the complete collapse of this once robust and lucrative salmon industry and all that relies on it. There is RAMPANT, shameful misinformation being spread about the importance of these dams by our own governmental agencies; NOAA, BPA and ACE. Their FAQs are full of propaganda to justify the existence of these dams. The bottom line is, these dams are benefitting few and harming multitudes. There is a reason they have been controversial since they were first proposed. There is a reason they have been identified as the best way to save our dwindling wild salmon runs. There is a reason the Army Corps of Engineers said that breaching the dams was the best way to save these salmon in their own Environmental Impact Statement of 2002. The damage these dams do to our environment far outweighs the meager benefits enjoyed by these few. There are other ways that already exist to get wheat to market. There are other ways that already exist to provide the power our region needs. There is no other way to save these fish that are a critical component to our ecosystem as a whole and are the lifeblood to our communities our commercial and recreational fishermen, our tribes, and our people.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. The power generated from the four lower Snake River dams is used to meet Bonneville's collective power obligation, most of which is sold to meet the loads of publicly owned utilities, such as municipalities, rural utilities, and public utility districts. (See EIS Section 3.7.2.5, Bonneville Power and Transmission Customers). It is true that the region has added substantial amounts of wind and solar generation; this is factored into the No Action Alternative. The EIS analysis finds that under Multiple Objective alternative 3, which includes breaching the four lower Snake River Dams, the region would roughly double its risk of power shortages unless and until new generation is acquired. See Section 3.7, Effects on Power System Reliability, page 3-903, in the Draft EIS. The EIS finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. See Section 3.10 for a discussion on Transportation and Navigation effects. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multiple objective alternatives (MOs) on recreation (Section 3.11). The potential effects to recreational fishing are based on the description of effects to resident and anadromous fish in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. The co-lead agencies are engaging in government-to-government consultation with the Tribes, and several Tribes are cooperating agencies on the CRSO EIS. Fisheries tribal interests are described in Section 3.15.4. Additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis in Section 3.11, including Tribal interests in Section 3.11.3.7. Many sections of Chapter 3 include a Tribal Interests sub-section at the end that attempts to summarize tribal issues by topic and Chapter 7 also includes additional information on the Preferred Alternative's impacts on these resources.
4504	1	mary_dryburgh@hotmail.com	N/A	I think there are many problems on the west side beginning with the water offshore from the Columbia river including predatory mammals and fishing. Is Portland and Seattle doing all they can to improve the water quality from those two cities that flow into the sound?	The scope of the EIS focuses on the area affected by the alternatives presented for operation and configuration of the CRS projects. Only those factors that could be affected by the configuration and operation of the CRS projects were carried forward into the effects analyses and those effects were analyzed in Chapter 3.4. Ocean predation and water quality impacts from cities like Portland and Seattle are outside of the scope of this analysis. The co-lead agencies agree, however, that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service website at: https://www.nwfsc.noaa.gov/research/index.cfm
4504	2	mary_dryburgh@hotmail.com	N/A	I have watched what happened when the Elian dams were removed on the Olympic Peninsula. While the results are now beautiful the amount of sediment that wash downstream from just that small river was huge.One can only imagine what would happen when the big dams on the Columbia and the Snake River were to be removed.	MO3 included a measure to breach the four lower Snake River dams and was not identified in the Preferred Alternative. For dam removals with large sediment deposits, predictions are generated for the amount of sediment estimated to erode and the downstream fate of that sediment. When there are potential impacts resulting from sediment release, mitigation measures are evaluated to reduce the impacts. For the Elwha and Glines Canyon dam (Washington, USA) removals, mitigation included a water treatment plant to address water quality impacts, increased levees or protection to address changes to flooding, a phased dam removal to reduce, but not eliminate, impacts to fisheries and the aquatic ecosystem and construction measures to protect cultural resources. The decision on what impacts and how to mitigate follow a robust formal process as part of an implementation EIS if a dam breach alternative is selected. The removal of the two large dams on the Elwha River exposed 27 million cubic yards of impounded sediment to fluvial erosion. This was approximately 84 years of sediment from the upstream watershed. Approximately 65 percent of the sediment was eroded, of which only about 10 percent was deposited in the fluvial system. This restored fluvial supply of sand, gravel, and wood substantially changed the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					channel morphology. The remaining around 90 percent of the released sediment was transported to the coast, causing around 60hectares of delta growth. A few years after dam removal, the Elwha River sediment loads returned to the new levels of an equilibrium watershed with connected sediment processes from the upper to lower watershed. The formulation of the MO3 drawdown and embankment removal measure for the four lower Snake River dams mirrored that developed in the 2002 Lower Snake River FR/EIS. While the volume of lower Snake River reservoir sediment is much larger than the Elwha, when scaled to the size of the watershed and average incoming sediment load, the volume composes nearly 60 years of incoming sediment load. Predictions indicate that of the 180 million cubic yards of sediment in the system, that the drawdown and bypass would not scour all the sediment from the reservoirs and as much as 50 percent of the total sediment stored in each reservoir would deposit outside the historic channel in the pre-dam floodplain up to 15 feet thick. The Snake River would largely abandon these deposits in place following breaching, stranding them above the active channel. After the embankment removal, the channelized flows are not predicted to frequently inundate or erode these residual sediment deposits. Approximately 70 percent of the sediment scoured from the four lower Snake River reservoirs is predicted to deposit in McNary pool downstream of the Snake River confluence in shallow areas prone to shoaling. Stored sediment from dam breaching would deposit in the Columbia River portion of McNary reservoir, downstream of the Snake River confluence which is predicted to decrease reservoir storage capacity by less than 5 percent. After the river has eroded and transported the reservoir deposits, the system is expected to transition to an equilibrium state where the annual watershed sediment load of approximately 2.4 million cubic yards per year that historically deposited upstream of Lower Granite Reservoir near the Snake-Clearwater confluence would be routed downstream to the Snake-Columbia confluence.
4510	1	Kurt Miller	Northwest River Partners	We also appreciate the detailed analyses performed regarding the power generation and environmental implications of the various Multiple Objective (MO) alternatives. We recognize that since work began in 2016, many of the regions assumptions around power supply have changed, with thousands of megawatts of coal-fired generation now on the path to early retirement. This new paradigm is critical to consider, and we are pleased that the DEIS included additional outboard analyses to reflect this important change in the regions power supply resource stack.	The EIS did examine potential future coal retirements and identified future reliability concerns, consistent with the concern voiced in the comment. See draft EIS, Section 3.7.3.2, No Action Alternative at pages 3-845-87, Table 3-123 and Section 2.3 of Appendix H, Sensitivity of LOLP to Assumptions about Coal Capacity, for additional details.
4510	2	Kurt Miller	Northwest River Partners	We also recognize that the science of predicting adult salmon returns is still very uncertain, which makes it highly challenging to predict the relative effect of any particular operation on salmonid populations.	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models (CSS and NMFS Life Cycle models) and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Unforeseen outcomes or unintended consequences will lead to adjustments using current in-season management teams through the Regional Forum.
4510	3	Kurt Miller	Northwest River Partners	The DEIS demonstrates that breaching the LSRD (MO3) could More than double the risk of region-wide blackouts1	The measure to breach the four lower Snake River dams that was evaluated in MO3, was not included in the Preferred Alternative identified in the Draft EIS. The effects of the Preferred Alternative (PA) on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the PA. However, because of the shape of the remaining hydropower generation in the PA, the loss of load probability was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary. The EIS analyzed two resource portfolios to replace the hydropower generation Multi-objective Alternative 3 (MO3, which included breaching the four lower Snake River dams), both of which maintain regional power system reliability. In the Draft EIS, see Section 3.7.3.5, pages 3-904-910. Under these replacement portfolios, regional power rate pressure increases (Section 3.7.3.5, at pages 3-918-924; and Table 3-166 in the Draft EIS). Without replacement resources, however, the statement about the effects of breaching the four lower Snake River dams on regional power reliability is consistent with the findings of the EIS. In the Draft EIS, see Section 3.7.3.5, Effects on Power System Reliability, page 3-903; and Appendix H, Table 2-1.
4510	4	Kurt Miller	Northwest River Partners	Add 3 million metric tons of carbon to the atmosphere each year from electricity production2	The EIS finds that under MO3, replacing the hydropower generation with natural gas power resources would increase regional CO2 emissions by 3.3 million metric tons, consistent with statement in the comment. See Section 3.8 of the EIS. However, the co-lead agencies did not identify MO3 as the Preferred Alternative. The Preferred Alternative estimates that GHG emissions would increase by 1.5% or 0.54 million metric tons compared to the No Action Alternative.
4510	5	Kurt Miller	Northwest River Partners	Cost up to $1 billion a year in additional power costs and raise Bonneville Power Administration (BPA) power costs rates by 50%3	The statement is consistent with the findings of the EIS on wholesale power rates under Multiple Objective 3 (which includes breaching the four lower Snake River dams). See Section 3.7.3.5 Electricity Rate Pressure, at pages 3-918-924 in the Draft EIS; see also Table 3-166 in the Draft EIS.
4510	6	Kurt Miller	Northwest River Partners	Harm the regional economy in the amount of $740 million a year in lost goods and services sold4	The statement is consistent with the findings of the EIS for the estimated regional economic effects under MO3. See Section 3.7.3.5 Social and Economic Effects of Changes in Power and Transmission in the Draft EIS.
4510	7	Kurt Miller	Northwest River Partners	Result in the loss of 4,900 jobs as a result of higher electricity rates5	The number of jobs cited in the comment is consistent with the findings of the EIS under MO3 with a renewable replacement resource portfolio. See Section 3.7.3.5, at 3-936 of the Draft EIS.
4510	8	Kurt Miller	Northwest River Partners	Reduce our ability to safely add new wind and solar power to the grid6	The statement in the comment that Multiple Objective Alternative 3 (which includes breaching the four lower Snake River dams) would reduce the ability of the power system to integrate new renewables is consistent with the findings of the EIS. See Section 3.7.3.1, Integration Services, at 3-832 in the draft EIS, and Appendix J, Section 4.3, Integration of Other Renewable Resources and Hydrosystem Flexibility Analysis at J-4-20 in the draft EIS.
4510	9	Kurt Miller	Northwest River Partners	Cost $458 million in social welfare from the loss of irrigated land and jobs for farm laborers7 Add 79,000 semi-trucks to the road each year8	As described in Section 3.12.3.4, under MO3, assuming that the entire 47,926 acres were no longer irrigated, the present value of the lost social welfare benefit under MO3 would be $447,174,000. In Section 3.10.3.5, the estimated increase in truck traffic is described. Under Scenario 1, the net additional trips is 13,515 truck trips compared to the No Action Alternative. Under Scenario 2, the total net additional trips under this scenario would be 32,249 truck trips compared to the No Action Alternative, with an additional 25,711 truck trips due to elevator to river port shipments. Truck shipments to shuttle elevators would decline under Scenario 2 compared Scenario 1, but would still be higher than under the No Action Alternative. Under Scenario 3, the net additional trips would increase to 79,250 truck trips compared the No Action Alternative, with the majority of that coming from elevator to river port movements.
4510	10	Kurt Miller	Northwest River Partners	While the numbers above are staggering, RiverPartners comments will demonstrate that the DEIS analysis does not go far enough to capture the full socioeconomic harm related to MO3 and MO4, which would have destructive and widespread impacts across the Northwest.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
4510	11	Kurt Miller	Northwest River Partners	RiverPartners comments will also demonstrate that there is a lack of scientific evidence to support M03, MO4, or the Preferred Alternatives higher proposed spill levels, which will result in the exceedance of 115% Total Dissolved Gas (TDG) levels.	In its analysis of effects, the Draft EIS used current high quality information, including models and studies published in peer review science journals. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address this uncertainty, the Preferred Alternative will be implemented using a robust monitoring plan and adaptive management plan. The impacts of the other alternatives were also evaluated with the CSS, COMPASS, and Life Cycle models.
4510	12	Kurt Miller	Northwest River Partners	Lastly, RiverPartners encourages the Action Agencies to work diligently with stakeholders to help threatened and endangered salmonid and orca populations in ways that do not diminish our critical hydroelectric resources. RiverPartners believes that more fully addressing the harmful impacts of avian predation is an excellent opportunity for this partnership.	The Preferred Alternative includes a large suite of predation mitigation measures. Some of which include maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary.
4510	13	Kurt Miller	Northwest River Partners	ENERGY EQUITY, SOCIOECONOMICS, RELIABILITY, AND DECARBONIZATION Warning Signs of An Energy Shortage Regional power planners are in unison that the Pacific Northwest is headed for an electricity shortage. The Northwest Power & Conservation Council10, the Northwest Power Pool11, E312, and Energy Strategies13 have all issued significant warnings about a potential energy shortage or even blackouts resulting from the retirement of thousands of megawatts of the regions coal plants. Notably, all these forecasts assume that the LSRD remain in place. As noted above, as disturbing as this risk is, the CRSO DEIS indicates that removing the LSRD from the resource mix would more than double the possibility of blackouts in the region. In the midst of the coronavirus pandemic, many people have come to realize the critical dependence we have on basic services, like electricity. Right now, the nation is contending with the lack of hospital beds, medical equipment, personal protective equipment, and cleaning supplies. Imagine how these problems would be amplified by a region-wide loss of electricity. The grid must be ready for emergencies, or we risk making a crisis like this much more severe. It is also important to note that an energy shortage does not have to result in blackouts to be devastating. During the Western Energy Crisis of 2000-2001, the Northwest did not experience blackouts. However, the efforts to buy power to avoid blackouts cost the region thousands of living wage aluminum industry jobs, and retail energy bills skyrocketed. Even the Bonneville Power Administration had to hike its rates by 45% to cover the increased costs. In California, where blackouts are already occurring due to climate change and Pacific Gas & Electrics weakened infrastructure, a two-class electricity system has developed. Well-to-do customers who can afford solar rooftops, smart inverters, and backup generation are able to maintain electricity, while poorer communities cannot.14 Whether from blackouts or skyrocketing prices, it is imperative that our region is not exposed to the effects of an energy shortage. Because of the severe consequences that would be felt as a result of an energy shortage, RiverPartners also encourages the Action Agencies not to assume that the current COVID-19 economic slowdown serves as a reliable predictor of longer-term demands for electricity. It is far too early, and there are too many unknowns to reliably depend on a lower level of long-term demand for electricity, especially as the region contemplates economy-wide decarbonization goals that would likely shift demand from natural gas to electricity. Because the Action Agencies are directly responsible for grid reliability, it would not be appropriate to plan to a lower level of demand until we have more direct evidence of what the economic recovery will look like.	The comment makes various statements about the importance of a reliable power supply and grid as well as the potential resource adequacy concerns raised by recent analyses. Information presented in the EIS is consistent with these statements. Regarding the statement about lower potential demand, although the EIS analysis preceded any slowdown that could be attributed to the COVID-19 pandemic, the analysis relied on the high-quality information from the Northwest Power and Conservation Council for load and power data.
4510	14	Kurt Miller	Northwest River Partners	Vulnerable Communities Across the Northwest Would Be Disproportionately Affected by Dam Breaching or High Spill Levels As mentioned above, the nation has yet to determine the full effects of the COVID-19 pandemic on public health and on the economy, and it may be a long time before we can do so. However, we do know that hundreds of thousands of employees have been laid off from their jobs in the Northwest alone. The DEIS shows that dam breaching (MO3) or sustained high spill levels (MO4) would create an unbearable burden for many homes. As referenced above, the DEIS calculates the cost of replacing the full capabilities of the LSRD with a carbon-free portfolio of resources, such as solar, batteries, and demand response to be as high as $1 billion annually. This value is very consistent with the third-party analysis performed by a leading energy consulting group, EnergyGPS, earlier this year.15 As noted above, the DEIS shows that cost would equate to a 50% increase in BPAs wholesale power rates. Based on a general rule that power supply costs represent roughly half of total retail bills, that would equate to a 25% increase in monthly electric bills for the millions of residential and business customers who get their electricity from BPA requirements utilities. The DEIS indicates that the financial cost of MO4 would be even higher than breaching. This cost increase is not affordable to most people in the region, especially in light of the massive job losses mentioned above. Early reports show that the people most affected by job losses related to the COVID-19 pandemic have been lower-wage earners.16 In a best-case scenario, where the unemployed are able to quickly find jobs after COVID-19 related shutdowns are over, it will still take significant time for these	The statement that the cost of replacing the lower Snake River dams' full capability with renewables is up to $1 billion is consistent with the findings of the EIS. See Section 3.7.3.5, at 3-918-924; see also Table 3-166. The statements regarding the power-related regional economic impacts under MO3 and MO4 are consistent with the findings of the EIS. The statistic that wholesale power rates under MO3 would increase up to 50 percent is also consistent. The EIS did not use the rule of thumb described by the comment to calculate end user retail rate effects. Instead, the EIS relied on historical power rate data from the available sources. Further information on the methodology for retail rate effects can be found in Section 3.7.3.1, Methodology, of the EIS. Additional information on the effects of the alternatives on minority populations, low-income populations, or Indian tribes can be found in Sections 3.18 and 7.7.20 (Environmental Justice).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				workers to achieve solid financial footing due to months of lost income. Implementing MO3 or MO4 and thereby substantially raising customer electricity bills would only serve to exacerbate the economic inequalities in the region.	
4510	15	Kurt Miller	Northwest River Partners	Many Traditionally Underserved Communities Are Dependent on Dams It is important to understand that communities across the Northwest have come to depend on dams to sustain their communities. Dams protect them from deadly flooding, provide irrigation for farming and jobs for agricultural workers, and create gathering points for recreation. At a press conference on Monday, March 2, Franklin Public Utility District public relations manager Mike Gonzalez stated that for his community of Pasco, Washington, Keeping the [lower Snake River] dams is a matter of social justice. Gonzalez shared that approximately 70% of Pascos residents identify as Latino/Latina and nearly 30% speak English as a second language. Additionally, Pascos Latino community provides a crucial source of labor for agriculture, and that irrigation from the lower Snake River dams supports the agricultural jobs that many people in his community rely upon for a secure economic future. He stated that if the dams were breached, the expected electric bill increase for Franklin PUDs customers would be as much as 30% and described the potential impact as devastating. Pasco, Washington is just one example of the diverse communities that depend on hydroelectric dams throughout our region. Without Ice Harbor Dam, 48,000 acres of farmland could lose access to irrigation in the Tri-Cities region17. As the DEIS notes, the loss of this irrigation would result in a $458 million loss to social welfare. It would mean the loss of jobs and homes, and it would deprive communities of a necessary economic base to support schools and social welfare programs. It is worth noting that during the COVID-19 pandemic, agricultural workers were deemed essential critical infrastructure workers by the federal and state governments and that agricultural communities have continued to risk their own health safety to ensure that food is available.	In Region C (lower Snake River) and potentially Region D (mainstem Columbia River) around the confluence of the lower Snake River, MO3, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative (as described in Section 3.12), water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams will reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected. Additionally, transportation of farming goods would expect to move off river and on to rail or trucks, as there would be a complete loss of commercial navigation on the lower Snake River and could not be feasibly mitigated. All ports along the Snake River would lose access to the navigation channel. Some ports at the confluence or the Snake and Columbia River could dredge new channels to the Federal channel in the confluence (McNary reservoir) to maintain access. Private or public entities or businesses could take actions and/or build infrastructure to extend pumps or water supply access for water. Ports and farmers can likewise change their transportation modes or connect to the navigation system at a different point on the river. The federal co-lead agencies would not mitigate for these impacts to water users or ports. See Chapter 3 analyzes the social and economic effects of implementing a dam breaching alternative (MO3) and Chapter 5 for mitigation discussion. Additional information on the effects of the alternatives on minority populations, low-income populations, or Indian tribes can be found in Sections 3.18 and 7.7.20 (Environmental Justice).
4510	16	Kurt Miller	Northwest River Partners	The LSRD Are Critical to Our Clean Energy Future We live in a carbon-constrained world due to legitimate concerns over climate change. To address these concerns, in 2019 the State of Washington passed a clean energy law that will mean the end of coal-fueled and natural gas-fueled generation in the state. Other regional government agencies have committed to carbon-free energy goals or are examining similar plans. Additionally, there have been calls for much more penetrating decarbonization goals for the Northwest economy. One such call has been for a requirement for all commercial buildings and new homes to get their heating and appliance-related energy from electricity instead of natural gas. According to a 2018 study, such a shift would likely double the regions peak electricity demand.18 Even without these calls for economy-wide decarbonization, the challenge of achieving the Northwests existing clean energy mandates means that thousands of additional megawatts of wind and solar power will be needed. As you know, in addition to being renewable, wind and solar power share a common trait they are intermittent. This means their electric output fluctuates based on the availability of wind and sunshine. The problem is that if the supply and demand for electricity arent in perfect balance every second, blackouts can occur. As a result, in the regions effort to add new renewables to the grid, hydroelectricity has become even more critical, because dams can store water and release it past hydroturbines to generate electricity when needed. The storage and release of water can be matched perfectly with wind and solar power to safely balance the grid. As the CRSO DEIS indicates, BPA will often carry up to 25% of its hourly reserves on the LSRD19in partto balance renewables on the grid. The CRSO DEIS notes that the LSRD provide roughly 1,100 average megawatts of carbon-free electricity each year, but they can provide over 2,000 megawatts under the right conditions.20 This flexibility makes the LSRD vital as the Northwest moves to a more renewable generation portfolio. The DEIS demonstrates that the LSRD capabilities could be replaced by natural gas-fueled resources, but that these fossil-fuel resources would add 3 million metric tons of carbon to the atmosphere each year, which equates to roughly a 10% increase in the entire Northwest power sector carbon emissions. Clearly, that would be a step in the wrong direction given the existential threat that climate change poses. As a result, it is critical that the Action Agencies do not adopt a plan that diminishes or eliminates the carbon-free capabilities of LSRD.	The comment contains multiple statements about the importance of hydropower for achieving regional clean energy goals and integrating renewables onto the grid. Although it is beyond the scope of the EIS to analyze the role of hydropower in achieving specific clean energy goals, the EIS does find that replacing the hydropower generation of the four lower Snake River dams would increase greenhouse gas emissions from power generation. See draft EIS, Section 3.8.3.5 at pages 3-1009-1010 in the draft EIS. The statements regarding the variability of other renewables and the importance of the four lower Snake River dams for integrating new renewables are consistent with the findings and discussions in the EIS. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907.
4510	17	Kurt Miller	Northwest River Partners	Need for Additional Economic Analysis for MO3 RiverPartners would like to mention one area of specific concern, which is the economic analysis performed for MO3. The DEIS did not evaluate the full amount of lost economic benefit associated with higher transportation from dam breaching (MO3). [graphic included in document: Supply Shock] Economic theory is clear that higher input costs (also known as a Negative Supply Shock) result in a depressed total volume of goods sold at higher prices (see figure to the left). According to the DEIS, breaching the four lower Snake River dams (LSRD) has the potential to greatly increase transportation rates for shippers who currently rely on barging to get their goods to market. For farmers, that means that they will be able sell less product and that the price of the product will be more expensive to buyers. This outcome results in a loss of economic value (price times quantity). This loss is depicted in the figure to the left as the difference between the green-dashed box and the yellow-dashed box. It is very important that the Action Agencies capture this lost value in the EIS analysis. Otherwise, there is a risk of significantly underestimating the costs of MO3.	Generally speaking, the commenter is correct that most products face downward facing demand curves. The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the furthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most negatively impacted. The EIS recognizes that there is no guarantee wheat grown in the Northwest will be competitive now or in the future because there are many factors that influence international commodity markets (e.g., trade agreements, the U.S. dollar, global supply, etc.). However, the analysis finds that the cost to transport wheat to market would continue to be lower than costs paid by other wheat growers in the United States (e.g., the Dakotas and Midwest). Favorable conditions for Northwest wheat growers that help them stay competitive are: (1) the natural environment of the Palouse region (weather, soils) is ideal for growing this type of wheat, which leads to some of the highest yields per acre in the world, and (2) proximity of Northwest export ports.
4510	18	Kurt Miller	Northwest River Partners	SCIENTIFIC REVIEW Hatchery Assumptions BPA provides funding of mitigation projectssuch as hatcheriesin the Snake River Basin. These projects are implemented by local, state, tribal, and federal entities. The funding of many of these programs is directly tied to the operation of the LSRD. Because MO3 would result in the breaching of the LSRD, the DEIS acknowledges continued funding of mitigation efforts for the LSRD may not be required under MO3.21 Birgit Koehler, Policy Lead for Power on the Columbia River System Operations Environmental Impact Statement highlighted this point in her public comments, There would be no line item in BPAs future budgets for Snake River hatcheries and habitat improvement.22 We note that the DEIS acknowledges the huge role that hatcheries play for Snake River salmonid populations. The DEIS states, . . . reductions in hatchery fish could reduce the numbers of juvenile Snake River Chinook by as much as 85%. This reduction in the number of hatchery fish would likely [also] result in a reduction of these predicted survival rates of wild Chinook because of increased predation rates However, the DEIS concedes that, COMPASS and CSS models do not account for this potential major reduction in juvenile fish production. RiverPartners is highly concerned that such a major impact was not quantified in the model runs. We note from having participated in all six of the CRSO DEIS public teleconferences that a great many proponents of MO3 have argued that the only way to save salmon and endangered Southern Resident orcas is to adopt MO3. However, their views might be very different if they were aware of the quantifiable impact that the potential loss of hatchery fish could mean for orcas and for cultural, commercial, and recreational fisheries. As a result, we encourage the Action Agencies to re-run these models to include the reasonable assumption that LSRD mitigation hatcheries could lose their funding as a result of MO3 implementation. The new model runs would give the Action Agency decisionmakers a much more informed basis for determining the best Preferred Alternative for the Columbia River System.	This is correct. Modeling of alternatives for the CRSO EIS did not consider additional mitigation programs such as hatchery production or habitat restoration projects, but existing hatchery production funded by the co-lead agencies is included in the No Action Alternative. Additional mitigation program measures are described in the EIS in Chapter 5. However, it would not be feasible to rerun scenarios of MO3 using NMFS COMPASS and CSS with Snake River hatchery production not included. The COMPASS model relies on the record of hydrosystem survival data estimated with both hatchery and wild tagged Chinook and steelhead. The NMFS Lifecycle model already reports only wild spawner abundance. Likewise, the CSS Chinook lifecycle model in the Grande Ronde/Imnaha also only included wild spawners. For both models, density related effects in downstream locations such as the mainstem, estuary and ocean could only be estimated with hatchery fish present.
4510	19	Kurt Miller	Northwest River Partners	Background on Competing Models We provide this section on modeling as a brief introduction to the following sections on Latent Mortality and TDG levels. As referenced above, two models have been relied on in the region to predict the effects of alternative juvenile salmonid passage methods and their effects on Columbia Basin adult salmonid returns. One model is the Life Cycle Model (LCM) used by the NOAA Fisheries Science Center. The other model is the Comparative Survival Study (CSS) model used by the Fish Passage Center. These two models have been at odds, with the CSS model predicting much higher adult salmon returns associated with increased spill levels and/or dam breaching than the LCM model. One major reason for the disparity between the CSS and LCM model results is that the CSS model depends on a theory referred to as latent mortality in its attempt to predict the rate of returning adult salmonids. The latent mortality theory posits that although juvenile salmon have a very high survival rateapproximately 96-97% averagepast each of the lower Columbia River dams and LSRD, that the act of going through fish bypass passage structures and powerhouses negatively impacts the health of juvenile salmonids and results in lower SARs. This theory suggests that the effects of the dams on salmon are not fully captured by juvenile migration survival rates. Therefore, according to the theory, more spill or dam breaching is needed improve the rate of adult salmon returns, also known as smolt-to-adult returns (SARs).	The co-lead agencies agree with this characterization.
4510	20	Kurt Miller	Northwest River Partners	CSS Model & the Challenge of Correlation Vs. Cause A difficulty for proponents of the latent mortality theory is that it is very hard to scientifically prove. The Action Agencies have acknowledged this challenge in the DEIS with the following statement, The degree to which latent mortality is affecting salmon and steelhead is one of the critical uncertainties in this EIS analysis.25 (emphasis added). The task of proving the existence of latent mortalityor its corollary that more spill is better for adult returnsis difficult because the ecosystems in which salmonids live are highly complex and constantly changing. In terms of in-river survival, SARs can be affected by factors including, but not limited to the number and type of salmonid predators, in-river harvest, river flows, river temperatures, pollution, the type and number of competing organisms, and spill levels. Because salmonids tend to spend most of their lives in the ocean, the model must also contend variables that are even more difficult to track. These variables include but are not limited to the availability of prey, the type and number of predators, the amount of in-ocean harvest, the type and number of competing organisms, pollution, acidity, and ocean temperatures. These challenges are summarized in the following quote from the Independent Scientific Advisory Board (ISAB), It is unlikely that overall changes in SARs [smolt to adult returns] can be isolated to conclude that spill is the causative factor for the system. The CSS approach uses correlations which do not by themselves determine cause and effect. There are many confounding factors and indirect effects of spill on fish survival including predation and other mortality in the reservoirs, deployment of new spillway weirs, delayed mortality, ocean conditions, habitat restoration activities, changes in toxic contaminants and other factors. Additionally, as mathematicians have noted, there is an imbedded challenge to isolating the effect of a particular variable when that variable, itself, is highly correlated with other model variables. This statistical concept is known as	The co-lead agencies acknowledge the many challenges associated with determining the magnitude of latent mortality associated with CRS operations. It it also acknowledged that further evaluation of all the models used in this process will continue over time. Given the challenges of determining and isolating a causal mechanism, the co-lead agencies intend to work with regional experts in salmon biology and quantitative analysis in an effort to develop a robust monitoring plan to reduce as much uncertainty as is possible in this complex situation. The co-lead agencies expect this process to take time to reduce the impact of multi-year variation in local, regional, and larger geographic scales that impact Columbia Basin species.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				multicollinearity, which is defined as, The existence of such a high degree of correlation between supposedly independent variables being used to estimate a dependent variable that the contribution of each independent variable to variation in the dependent variable cannot be determined. In this context, it has been documented by NOAA and others that many of the variables assumed to affect adult salmon returns share a high degree of correlation among themselves. For example, shifts in river temperatures and ocean temperatures tend to be closely related. Also, runoff volume, amount of spill, and speed through the hydroelectric system tend to be closely related. Scientists have also noted a correlation between ocean temperatures, prey availability, and the abundance of salmon predators. In terms of predicting SARs, the challenge that arises is knowing how much each of the highly correlated explanatory variables is associated with changes in adult salmonid returns or if there is a deeper, underlying factor of which the model is not aware. A 2016 paper by NOAA Fisheries captures one example of the issue described above. NOAA writes, One concern for salmon is that unfavorable environmental conditions can impact multiple life stagesLarge-scale climate phenomena such as the PDO were already known to correlate with terrestrial precipitation patterns, but a new study further explores the relationship of these patterns with seasonal indices of the PDO and sea-surface temperature (SST) across the U.S. In support of the statistical difficulties listed above, we site a study written by Dr. John Skalski from the University of Washington School of Aquatic and Fishery Sciences, Over time, numerous investigators have modeled salmonid survival and adult return rates as functions of in-river and/or oceanographic covariatesThe majority of the analyses use basic multiple linear regression techniques and ignore higher-order processes, interactions, and the possibility of optima, thresholds, or spline relationships. The multicollinearity of in-river, ocean, and between in-river and ocean covariates makes identification of driving variables difficult at best We encourage the Action Agencies to consider these significant challenges to proving the veracity of the latent mortality theory as you determine how much credence to give to the CSS model results.	
4510	21	Kurt Miller	Northwest River Partners	CSS Model & Simplifying Assumptions In additions to the shortcomings identified above, the CSS model excludes potentially important variables that could influence its model outcomes. That issue is acknowledged by the ISAB in the following critique of the CSS model, six freshwater and marine variables examined by Haeseker et al. (2012) water transit time (WTT), spill, date of migration, upwelling, sea surface temperature (SST), and Pacific Decadal Oscillation (PDO) had all been identified as important in other studies, so the choice of these variables has support in the literature (Muir et al 2001, Scheuerell and Williams 2005, Schaller and Petrosky 2007, Petrosky and Schaller 2010). Nevertheless, to address alternative hypotheses additional candidate variables need to be evaluated, for example, biological measures of top-down (predation) and bottom-up (primary and secondary productivity) forcing, individual fish (age, growth, and condition), density-dependent effects, and anthropogenic forcing (habitat, harvest, and hatchery). We also note that the CSS models exclusion of juvenile fish size was identified as a problem in the 2019 NOAA Fisheries Science Center study.31 (Discussed in more detail in the subsequent section). Another potentially important explanatory variable exclusion is identified in the ISAB reference above. The CSS model explicitly excludes harvest quantities as a model variable. It tacitly assumes that year-to- year changes in harvest levels are not significant, so the model can exclude this variable and still produce meaningful results. A major problem arises, however, if this tacit assumption isnt accurate. It would mean that the model could conclude a spill regime from a particular year had a more meaningful impact on SARs than was truly the case. To elaborate, the model might see that some years with higher levels of spill corresponded to higher salmonid returns in later years. However, if the reason for the higher return rates was due to a much smaller harvest quantity, then the model could make false or even inverse predictions for future outcomes.	The co-lead agencies concur that model complexity is a critical factor when evaluating and using complex ecological models. This will continue to be an area of emphasis as information is gathered under the actual operating conditions of the Preferred Alternative. Both NMFS and CSS models have undergone and will continue to undergo independent peer review, both through this CRSO EIS process and into the future. Variables mentioned in this comment such as harvest assumptions and fish condition were both raised by the ISAB and through the IEPR process. The co-lead agencies acknowledge the inherent uncertainty that comes from basing decisions on models and will continue to improve and refine all of the models used through this process.
4510	22	Kurt Miller	Northwest River Partners	CSS Model & the Potential for Spurious Results It deserves notice that the Action Agencies are recommending higher levels of spill as part of the Preferred Alternative, due to CSS model predictions. Because the CRSO DEIS Preferred Alternative depends on these predictions, we encourage the Action Agencies to carefully test the reasonableness of the harvest assumption, as well as other simplifying model assumptions for which data is available. If it is scientifically demonstrated that harvest levels represent a substantial and significantly volatile value from year-to-year, such an outcome could invalidate the values produced by the CSS model. There is already good reason to question some of the CSS model assumptions and conclusions. For example, recent peer-reviewed study from NOAA Fisheries Science Center determined that there is little-to-no evidence of dam-related latent mortality. The study found that fish which go past turbines or through fish passage systems experience about the same estuary and ocean mortality levels as fish that travel through spillways.32 The study found that fish bypass structures tend to draw in smaller fish, which inherently have lower survival in the ocean. After controlling for size, these fish survived at about the same rate in the ocean as the fish that go through spillways and turbines. The size of the juvenile fish was the driving factor in ocean survival, not the route of dam passage. 33 Figure 2 (below) is from a separate peer-reviewed paper published in the Proceedings of the National Academy of Sciences. It compares survival of two groups of smolts. One group migrated through the LSRD and the other group migrated from the Yakima River. [graph included in document: Survival of Yakima River and Snake River smolts] The results are consistent with a lack of delayed mortality findings. The smolts from the Yakima River returned as adults at nearly the identical rate of smolts from the lower Snake River. In terms of basing public policy on model-based outcomes, it is critical to note that the CSS model performed very poorly in its predictive capabilities. Similarly, a separate peer-reviewed paper from March 2014 found no evidence of dam-caused latent mortality in salmonids.35 These important findings should encourage the Action Agencies to question assumptions and predictions about the benefits of spill, dam breaching, and the role that the lower Snake River and lower Columbia River dams play in overall salmon mortality. Further, if evidence mounts that the CSS model is producing spurious results, the Action Agencies must be willing to abandon its advice. In preparation for this potential outcome, we urge the Action Agencies to maintain, under adaptive management principles, the ability to reduce or eliminate spill for fish, if the basis for fish-related spill is nullified.	NMFS' Northwest Science Center study referred to in this comment was carried out by coauthors who contribute to the NMFS COMPASS and Life Cycle models (Faulkner et al. 2019). This study investigated selective use of various dam routes as a function of fish size, and by extension, addressed a causal relationship between route of passage and subsequent survival rates. Multiple mechanisms of delayed mortality or 'carryover effects' between experiences in one lifestage influencing survival or physiology in subsequent lifestages (Gosselin et al. 2018). These include transportation related delayed mortality, injuries caused by passing multiple dams via any route, delays caused by reservoir and dam passage, and exposure to toxins. NMFS' Life Cycle model chose to consider the effects of delayed mortality caused by any mechanism by treating it as a sensitivity analysis. Citations: Faulkner, J. R., Bellerud, B. L., Widener, D. L., & Zabel, R. W. (2019). Associations among Fish Length, Dam Passage History, and Survival to Adulthood in Two At Risk Species of Pacific Salmon. Transactions of the American Fisheries Society, 148(6), 1069-1087. Gosselin, J. L., Zabel, R. W., Anderson, J. J., Faulkner, J. R., Baptista, A. M., & Sandford, B. P. (2018). Conservation planning for freshwater-marine carryover effects on Chinook salmon survival. Ecology and evolution, 8(1), 319-332. The co-lead agencies agree with your point on adaptive management: the Preferred Alternative includes an adaptive management plan (Appendix R). This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
4510	23	Kurt Miller	Northwest River Partners	Early Flexible Spill Results Disappointing The higher sustained spill operations pursuant to the implementation of the Flexible Spill Agreement in 2019 represented uncharted territory. While there have been periods throughout history with high levels of uncontrolled TDGs, 2019 was the first time in the operation of the Federal Columbia River Power System where TDGs were maintained at levels as high as 120% on a planned and sustained basis for the entire spring spill period. It will take years before most of the surviving 2019 juvenile migrants return, but the earliest signs point to poor results for both juvenile salmonids and returning adults. As an example, according to a NOAA Fisheries Science Center memo from September 19th, 2019 on juvenile survival for the 2019 migration season, The combined yearling Chinook salmon survival estimate from the Snake River trap to Bonneville Dam tailrace was 41.3% (33.8-48.9%), which was below the long-term average of 48.9%.36 The memo goes on to note that, The combined Snake River steelhead survival estimate from the Snake River trap to Bonneville Dam tailrace was 41.2% (26.1-56.3%), which was below the long-term average of 45.7%.37 We also note that in 2019, adult salmon were stalled repeatedly in their efforts to make it upstream past Little Goose Dam, due to increased spill levels. Correspondingly, Claire McGrath at NOAA presented the attached report to the U.S. Army Corps of Engineers Technical Management Team Meeting on 7/10/2019. According to the TMT meeting minutes, Ms. McGrath concluded, that despite varying results from the data tools, all of the indicators did consistently point to lower than expected conversion rates and slower travel times in the Lower Monumental to Little Goose reach. The 2019 YTD (as of 7/10) conversion of PIT-tagged adult Chinook from Lower Monumental to Little Goose was 96.2%, whereas the historical average for EOY conversion is 98.3%. Given that adult spring Chinook are a culturally prized fish with the greatest biological value, and near their spawning grounds in this scenario, this lower conversion rate could represent a significant reduction in survival.	The benefit of the Preferred Alternative's flexible spill to salmon and steelhead relies largely on reduction in PITPH, which is projected to result in increased SARs. Therefore, in-river survival doesn't tell the whole story. The commenter is correct in that it will take years to understand the true effect because adult returns are needed to measure the key effect, Smolt-to-Adult return rates. One year of in-river data to assess the benefits of flex spill is not adequate. The Preferred Alternative includes working with regional sovereigns to develop a study that will assess the effectiveness of increased spill regime on adult returns as well as assessment and adaptive management in order to address negative unintended consequences, such as long delays of adult migrants, or TDG-related impact on juvenile migrants.
4510	24	Kurt Miller	Northwest River Partners	Higher Spill Levels Based on Linear Assumptions As mentioned previously, the basis for the Action Agencies adopting spill levels in excess of 115% TDG is predicated on CSS model results showing higher adult salmonid return rates. We have already detailed good reasons to doubt the veracity of the CSS model conclusions. However, there is an additional reason to question the models output when it comes to spill levels of 120% TDG or higher. A known shortcoming of multiple linear regression models, like the CSS model, is that they need a straight line or linear relationship between the independent variables and the dependent variable. Once that linear relationship breaks down and becomes curvilinear, the models can lose their ability to accurately predict outcomes.39 In the case of spill levels with TDG in excess of 115%, we have a perfect storm which could lead to errant results from the CSS model. To elaborate, while spill levels have occasionally reached or exceeded 125% TDGthe recommended level in the Preferred Alternativethey have never been managed to achieve that level continuously over the entire spring period at all eight lower river dams. This deficiency of experience means that the CSS model lacks the data to appropriately interpret the relationship between spill and adult salmon returns under this new spill regime. In short, the CSS will assume that the linear relationship for lower levels of spill in its database will hold constant for higher levels of spill beyond the models experience. However, we note that the Washington State Department of Ecology (Ecology) found that spill levels in excess of 115% TDG are known to cause harm to aquatic life. Ecology states, The weight of all the evidence from available scientific studies clearly points to detrimental effects on aquatic life near the surface when TDG approaches 120%. The detrimental effects ranged from behavior changes to high levels of mortality after a few days. There were fewer effects on aquatic life at 115% TDG. Ecology strongly encourages implementing actions that increase salmonid survival without further increasing total dissolved gas. This finding tells us there is a significant risk that the CSS models linear understanding between spill and adult salmon returns may break down in this uncharted territory.	The commenter is correct. Some measures included in the alternatives have not been implemented with modern monitoring techniques in place such as PIT-based survival and travel time estimates or fish condition monitoring. Models and qualitative evaluations developed for the CRSO EIS drew upon a combination of scientific literature developed at locations outside of the CRS, and short-term observations within the CRS. For example, some data is available indicating dam routes and survival during within-season periods with high TDG have occurred during high flow conditions in 2011, 2017-2018. For lower Snake River dam breach conditions, modelers could draw on the lower Snake River dam drawdown experiment conducted in 1992 (Dauble and Geist), or use fish survival and travel time data from reaches just downstream or upstream of reservoirs in the CRS, for example. Eder et al. (2009). To address this uncertainty and minimize risk, the Preferred Alternative includes an adaptive management plan (Appendix R). This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts on juvenile migrants. TDG levels are regulated under the Federal Clean Water Act, and administered by the States. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a 5-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. There is considerable uncertainty in the effects; and therefore, monitoring was required by the states and EPA to ensure any adverse effects are detected and allow for adaptive management. Migrating salmon and steelhead may spend sufficient time at depths that will compensate for the high gas levels. However, fish and other organisms that spend extended times in less than a few meters of depth are at high risk. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. Please see Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. 4510	25	Kurt Miller	Northwest River Partners	Call for Explicit Direct Tests If the Action Agencies proceed with spill levels in excess of 115%, we call for explicit direct tests of the effect of high TDG levels on smolt survival in the river and, ideally, in the early marine phase after the smolts leave the river, where predators are abundant. The tests should be conducted with test and control groups. Such a test would be the most scientifically valid way to determine the effect of higher spills levels on SARs. There is some published observational evidence that smolts exposed to high TDG levels may suffer high sublethal effects not captured in laboratory experiments, possibly because high TDG levels physically impairs smolts and makes them more vulnerable to predators.41 However, the reported results are purely observational. We believe that, given the importance of the issue, an explicit scientific experiment testing in-river and nearshore coastal ocean survival of smolt groups exposed to varying levels of TDG is called for. A test focusing on relative smolt survival would directly examine the key issue and also reduce the number of years required for a meaningful analysis. We also encourage the Action Agencies to include clear language in the Final EIS that allows for adaptive management, should those high spill levels be shown, on a large scale, to be detrimental to either adult or juvenile resident or anadromous fish. Among the possible detriments, the Action Agencies should specifically consider delayed travel times for migrating adults. The language should make clear that spill levels will be reduced to 115% TDG on a permanent basis, should large-scale negative impacts on resident or anadromous fish be discovered.	Tests as described by the commenter have been deemed as not necessary by the water quality agencies in the region. TDG levels are regulated under the Federal Clean Water Act, and administered by the States. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a 5-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. There is considerable uncertainty in the effects; and therefore, monitoring was required by the states and EPA to ensure any adverse effects are detected and allow for adaptive management. Migrating salmon and steelhead may spend sufficient time at depths that will compensate for the high gas levels. However, fish and other organisms that spend extended times in less than a few meters of depth are at high risk. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. Please see Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
4510	26	Kurt Miller	Northwest River Partners	Mixed Science on Dam-Related River Temperatures Several public comments from the CRSO DEIS public teleconferences advocated for MO3 in response to high temperatures in lower Snake River reservoirs. It is important for the Action Agencies to recognize that damaging water temperatures are not unique to impounded rivers. While it was widely reported in 2015 that 250,000 returning adult Snake River sockeye perished during an exceptionally dry and hot summer, mass die-offs have been observed in undammed rivers as well. For example, in 1994, due to record high water temperatures, approximately 466,000 adult fish perished in the undammed Fraser River before reaching their spawning grounds.42 More recently, record breaking temperatures in Alaska led to die-offs in several undammed rivers. One event in particular, originally reported by NPR, highlighted the problem. An official estimate was not released, but biologists believe as many as 200,000 to 300,000 fish were in the river during the extreme heat event. In terms of studies on the direct effect that Columbia Basin dams have on river temperatures, the results are mixed. A 2003 EPA study indicated that dams may exacerbate temperature issues on the rivers, but a 2002 peer-reviewed study performed by Pacific Northwest National Laboratory showed that dams within the Columbia and Snake river basins moderate extreme water temperatures. the reservoirs decrease the water temperature variability. The reservoirs also create a thermal inertia effect that tends to keep water cooler later into the spring and warmer later into the fall compared to the un-impounded river condition. Also, in 2002, a team of researchers conducted a water temperature study on behalf of the U.S. Army Corps of Engineers. The team compared pre-LSRD measurements of water temperature from 1955-1958 to measurements taken after the LSRD were constructed. They found no evidence that river temperatures had increased as a result of the dams, and instead appeared to have remained unchanged or slightly lower. The team identified air temperature and flow levels as the biggest influences on temperatures in the river.45 In fact, air temperatures have trended upward significantly since 1955. Data available through the University of Washingtons climate change tools show that the average air temperature recorded near Kennewick, Washington, has increased at a rate of 0.37 degrees Fahrenheit per decade. These conditions would suggest higher water temperatures in the river over time, but as noted above the river temperatures have remained unchanged or slightly lower. There have been occurrences of spikes in temperature due to soaring air temperatures during heat waves, but these events are outliers, not the norm. Appendix 2 of this document includes a graph provided through the University of Washingtons Pacific Northwest Temperature, Precipitation, and Snow Water Equivalent Trend Analysis Tool. ased on this evidence, the LSRDs are highly unlikely to cause high water temperatures capable of harming salmonids. Rather, their impoundment effect may actually help buffer against extreme temperatures because larger water volumes are more difficult to heat. We ask that you consider the weight of this research in continuing to reject MO3 and MO4.	The co-lead agencies agree with the commenter's concern relating to water temperatures in the Columbia and Snake rivers and that is why the agencies have used current high quality data and resources available to model and evaluate impacts from operations described in each of the alternatives on water temperatures. It is well understood that the CRS dams have an impact on natural riverine processes as well as anadromous fish migration. This is discussed throughout the EIS document. A system water quality model was developed to look water temperature and TDG effects throughout the Columbia and Snake River system for this EIS. Breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges.
4510	27	Kurt Miller	Northwest River Partners	redation in The Columbia River Basin Avian An 11-year study conducted by regional biologists on upper Columbia steelhead smolts found that birds were responsible for between 31% and 53% of juvenile mortality in the river, and for steelhead, avian predation accounted for more mortality than all other sources combined.46 Comparatively, a study of lower Snake River steelhead populations produced similar results. To quote from the study, Avian predation was a major source of mortality in a 6-year study of ESA-listed Snake River steelhead.47 This high rate of predation carries on into the lower Columbia River as well. As noted by the ISAB, Smolt predation by Caspian terns and double-crested cormorants downstream of Bonneville Dam were also substantial and ranged from 14% to 28% of upper Columbia River steelhead smolts in the Columbia River estuary. Recently, presenters to the ISAB (Quinn Payton and Allen Evans, RTR, March 1, 2019) demonstrated results from their Joint Mortality and Survival (JMS) model. Using the 10-year dataset and partitioning sources of juvenile mortality, the model (Figure 11) estimated that in the absence of Caspian tern predation, UCR steelhead SARs would have been one (SARs 95% CRI of SARs = 0%-2%) to five percentage points higher (SARs 95% CRI = 3%-8%). In a presentation to the ISAB, Dr. Evans and Dr. Payton estimated that SARs, in the absence of terns would be, 3.2 times higher than observed averages for upper Columbia River steelhead.49 From these numbers it is clear that addressing avian predation of salmonids is foundational to healthy ESA-listed fish populations in the Columbia River Basin. We appreciate the efforts of the co-lead agencies to address avian predator disruption in the Preferred Alternative by including modification of the John Day Reservoir. Specifically, allowing The U.S. Army Corps of Engineers to raise John Day Dam Reservoir levels to decrease avian predation on ESA-listed juvenile salmon and steelhead in the lower Columbia River. However, much more must be done to control the fish-eating birds that significantly and adversely impact ESA-listed salmon and steelhead in the Northwest. Chapter 5 of the DEIS lacks a suitable level of specificity. We encourage the Action Agencies, in the Final EIS, to include a thorough and detailed plan so that regional stakeholders can have confidence in your solution. In terms of specific measures, we reference the Inland Avian Protection Management Plan (IAPMP) which was included as part of the 2008 Biological Opinion and intended to govern Columbia River System operations through 2018.50 The IAPMP was developed by the US Army Corps of Engineers and calls for management actions at Goose Island (Potholes Reservoir in Grant County, Wash.) and Crescent Island (McNary Reservoir on the Columbia River in Walla Walla County, Wash.) to dissuade Caspian terns from nesting at these locations. 51 The 2019 Biological Opinion proposed the continuation of IAPMP implementation to reduce the negative impact of avian predators on ESA-listed salmon and steelhead.52 However, as noted in the July 29, 2019 letter from the Priest Rapids Coordinating Committee (PRCC) to NOAA Fisheries Branch Chief Ritchie Graves in Appendix 3 of this document, the IAPMP requirements have not been fulfilled by the Action Agencies. As a specific example, the PRCC letter notes, In the 2019 BiOp, the U.S. BOR proposes to maintain the ropes and flagging and to monitor for tern presence on Goose Island throughout the Caspian tern nesting and salmonid smolt outmigration seasons of 2019 and 2020, until the proposed new BiOp is issued in September of 2020. However, the U.S. BORs proposed action and responsibility to the 2019 BiOp was not fulfilled in 2019. We note, for the 2020 season, that the Bureau of Reclamations budget for its Goose Island plan-of-action is only about 20% of what it had been for 2015-2018. The data demonstrate full funding for the full implementation of the actions & obligations of the IAPMP should be a top priority for the Action Agencies. We also adjure the Action Agencies to make the IAPMP more comprehensive. The plan should not be site-specific, but rather comprehensive in scope, since avian predators have demonstrated their ability to quickly move from one nesting site to another. The plan should also address other bird predators, such as cormorants, gulls, and pelicans.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative, which includes measures to reduce predation by avian predators, would provide benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The primary driver for these benefits to anadromous fish is increased spill during the juvenile fish migration. The Inland Avian Predation Management Plan (IAPMP) has been focused on reducing predation by Caspian terns with initial efforts being implemented at Goose Island (Potholes Reservoir near Othello, WA) and Crescent Island (McNary Reservoir near Burbank, WA). The objectives of the IAPMP have been met at these two locations in recent years and as of 2019, there has been a 49% reduction in the total number of Caspian terns nesting on the Columbia plateau region since implementation of the IAPMP begun (Collis et al. 2020; http://www.birdresearchnw.org/2019%20GPUD%20Final%20Report.pdf). Adaptive management efforts to dissuade incipient colonies that have formed following implementation of the IAPMP have been implemented where the co-lead agencies have authority and management responsibilities which includes Potholes Reservoir including at the NW Rocks starting in 2014 and at small islands in the northern portions of Potholes Reservoir starting in 2015. The co-lead agencies continue to monitor and adaptively manage all of Potholes Reservoir to dissuade terns from nesting on co-lead agency managed lands in the area and this is anticipated to continue as described in the Draft EIS. However, the co-lead agencies recognize that some Caspian terns have moved to other locations and that some of these locations are managed by other entities outside of the co-lead agencies current management abilities. The co-lead agencies will continue to work closely with these other entities in the region who have authorities and obligations to mitigate the impacts from avian predators to benefit ESA-listed salmonids as well as implement a new reservoir management operation for the John Day reservoir to dissuade nesting Caspian tern as described in the Draft EIS. The IAPMP was developed with the best information available at the time and gulls were not identified as warranting directed management efforts at nesting colony locations by the co-lead agencies at agency-managed properties at that time. The co-lead agencies propose to continue, under the Preferred Alternative, predation reduction measures such as hazing at the agencies' CRS facilities as described in the Draft EIS to ensure the operation of the CRS does not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The co-lead agencies can only address certain types of predation by gulls, such as when they are foraging within the direct footprint of the co-lead agencies' CRS facilities where the agencies have management abilities. Other entities in the region have authorities and obligations to mitigate the impacts from avian predators as well and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Management of gulls at Miller Rocks just upstream of Miller Island is not feasible by the co-lead agencies as they do not own or manage this property and therefore do not have the authority or abilities to manage avian predation at this location. The Bureau of Reclamation has been engaged with and funding actions associated with management of piscivorous waterbirds on the Columbia River plateau including at Potholes Reservoir since 2010. Starting in 2014 when the implementation of the IAPMP begun, BOR began funding their respective commitments associated with implementation of the IAPMP in coordination with the other co-lead agencies. While the Priest Rapids Coordinating Committee has funded additional avian predation efforts in the region, and agreed to fund all 2019 activities at Potholes Reservoir, the Bureau of Reclamation intends to continue implementing and funding future actions necessary to implement the IAPMP where they are the responsible agency.
4510	28	Kurt Miller	Northwest River Partners	Piscivorous Fish It is notable that both native and non-native piscivorous fish play a significant role in the mortality of juvenile salmonids. For piscivorous fish, and specifically, for Northern Pike, the opportunity exists to recommend that Chapter 5 (Mitigation) and Chapter 7 (Preferred Alternative) of the DEIS focus not only on ongoing-existing predation actions/programs but outline specific new mitigation actions. New mitigation/measures/actions (above those already being implemented) would include: Increase Northern Pike suppression efforts in areas above Chief Joseph Dam Develop a comprehensive Rapid Response Plan that would be implemented if/when Northern Pike are detected below Chief Joseph Dam. Increase early detection measures for Northern Pike in areas below Grand Coulee Dam. Reduce the opportunity for Northern Pike to emigrate out of areas above Albeni Falls Dam. This could be accomplished through increased Northern Pike management by the appropriate state and federal regulatory agencies. **Relevant Northern Pike/Predation Sections of the DEIS: 5.2.1.1 Bonneville Power Administration Fish and Wildlife Program-Predation section 5.2.1.7 Predation Management 5.4 Potential Mitigation for Alternatives- New Mitigation Actions Chapter 7 (Preferred Alternative)-Other Fish- line 3851	For habitat improvements as described in Chapters 2 and 5, Bonneville works with states, Tribes, and watershed groups to protect, mitigate, and enhance spawning and rearing habitat, targeting factors that limit fish survival throughout the Columbia River Basin. Bonneville has funded hundreds of projects across the basin to restore natural stream channels, reconnect estuarine tidal channels, enhance flow volume and timing, and expand cold water refuges and open access to habitat (www.cbfish.org). These habitat improvement actions provide both near-term and long-term benefits to anadromous and resident species, including bull trout and westslope cutthroat, including those that will help address the effects of climate change. Actions that improve connectivity and streamflow will provide a buffer against the effects of climate change. In addition to habitat improvement actions, Bonneville works with willing landowners to protect land by putting it under permanent conservation easement to further support habitat and fish conservation in the short and long term. The co-lead agencies recognize the ongoing threat of downstream invasion of northern pike under the No Action Alternative and there would be a minor decrease in boat suppression efforts under the Preferred Alternative. The analyses showed there would be a minor effect (up to one week of boat ramp access impeded) in wet years only, and the resulting overall effect to the invasion of northern pike would be minor. The co-lead agencies recognize and appreciate the importance of northern pike invasion as a regional issue, but, in this EIS process, the co-lead agencies developed mitigation for moderate to major effects of the multiple purpose alternatives as compared to the No Action Alternative. Because the impact to northern pike was minor, mitigation was not appropriate for this effect.
4510	29	Kurt Miller	Northwest River Partners	Pinniped The up-river migration of California and Stellar sea lions have increased pressure on adult salmonids as well. New federal laws have granted state and tribal agencies, including Oregon and Washingtons fish and wildlife departments, to conduct removal efforts andin the case of the most problematic individualshumanely euthanize a limited number of the sea lions.53 We point to the successful paradigm that the Columbia River Inter-Tribal Fish Commission (CRITFC) established in working with regional stakeholders and elected officials to amend the Marine Mammal Protection Act. It seems likely that the result of that work was the rebound of Willamette River steelhead seen this year from critically low numbers of recent years.54 We encourage the Action Agencies to follow CRITFCs path in addressing other sources of predation noted above.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Sea lion management decisions at Bonneville Dam rely on input from the Sea Lion Management Working Group. This Working Group is a collaborative effort with NOAA, USFWS, various Tribes, and the co-lead agencies. The co-lead agencies works to minimize the effects of sea lions on salmon by implementing Best Management Practices specified in the NOAA Biological Opinion and by implementing recommendations developed by the Working Group. The co-lead agencies will continue to use this process to minimize the effects of sea lions on salmon within their authorities. The EIS discusses the Working Group and sea lion management in Section 3.5, 3.6 and Chapters 5 and 7. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.

4510	30	Kurt Miller	Northwest River Partners	Salmon Recovery Hinges on Ocean Conditions Northwest RiverPartners has historically advocated for an All-H approach (hydro, habitat, hatchery, harvest) to salmon recovery. These principles still hold true, but we also note that too often, the habitat that gets policy makers attention is in-river habitat. Scientific research shows that the ocean deserves more attention. Studies have found that the oceans absorb as much as 30% of the climates excess carbon55 and 90% of its excess heat.56 This absorption leads to warmer waters with higher levels of acidity and lower levels of oxygen. The Intergovernmental Panel on Climate Change issued a 2019 report that warned of the highly negative impacts of carbon and heat absorption on marine life and fish populations. The report states, Projected ocean warming and changes in net primary production alter biomass, production and community structure of marine ecosystems. The global-scale biomass of marine animals across the foodweb is projected to decrease by 15.0 5.9% (very likely range) and the maximum catch potential of fisheries by 20.524.1% by the end of the 21st century relative to 19862005 under RCP8.5 (medium confidence). These changes are projected to be very likely three to four times larger under RCP8.5 than RCP2.6. This warning comes at a time when were already seeing the oceans depleted of critical prey that salmon rely on. As an example, Pacific herring are an important prey species for adult salmon in the ocean. The Washington Department of Fish and Wildlife is studying the decline of Pacific herring in the Salish Sea, which has been trending downward since the 1970s.58 They, too, are susceptible to poor ocean conditions and have been heavily harvested. Some Pacific herring stocks have declined by as much as 97%, and there has been a renewed discussion to potentially list these fish as threatened or endangered under the Endangered Species Act.59 Given this information, it is not surprising that NOAA Fisheries researcher Lisa Crosier recently stated that scientists worldwide have been documenting, almost synchronous declines in salmon populations, due to climate change.60 News articles this past year confirm the fact that the number of returning adult salmon to rivers from southern Oregon to southeastern Alaska have suffered from hostile ocean conditions.61 Most of these rivers do not have dams, which points to larger causes driving the declines. These dire results underscore the fact that climate change must be addressed to restore healthy salmonid populations. The pressure is further increased by warnings that suggest that our oceans may be approaching their threshold for carbon and heat absorption, which could lead to warming as monumental as the event that ended the last ice age.62 Given the serious implications of climate change for both marine and non-marine species, removing or diminishing carbon-free resources is a step in the wrong direction. This statement is especially true for the LSRD. As noted above, the ability of the LSRD to store and release water past hydroturbines is needed as we work to safely add intermittent renewables, like wind and solar power, to the grid.	While none of the alternatives would affect ocean conditions, the co-lead agencies recognize that these conditions are a major driver for adult fish returns and that numerous studies have shown the importance of this environment in the return of adult salmon and steelhead (Peterson et al. 2019). As such two of the models used in these analyses, NMFS Lifecycle and CSS models, use metrics of ocean productivity to predict adult returns.
4510	31	Kurt Miller	Northwest River Partners	The Role of the LSRD NOAA Fisheries has determined that Snake River salmon are not the limiting factor for SRKW populations. According to NOAA Fisheries, Since they feed on many different salmon stocks at different times, though, no one salmon recovery action on a single river, such as breaching dams on the Snake, would itself bring about the recovery of Southern Resident killer whales. In addition, the relative size of the Snake River salmon stocks compared to others on the West Coast means that increases in their numbers, whether from breaching dams or otherwise, would result in only a marginal change in the total salmon available to the killer whales. NOAA Fisheries also found that the hatchery Chinook in the Columbia and Snake river basins more than compensate for fish lost as a result of dams in terms of availability for orca whales.65 A joint 2018 report by the Washington State Department of Fish & Wildlife and NOAA Fisheries determined that Snake River Chinook salmon were only the 9th most important food source for SRKW. Unsurprisingly, the top priority SRKW food stocks came from the Puget Sound.66 In 2018 NOAA Fisheries noted that Puget Sound Chinook salmon populations hadnt seen the improvement experienced by other West Coast Chinook salmon populations in the last decade. The abundance of Chinook salmon returning to Puget Sound rivers has scarcely changed in recent decades, in large part because much of their habitat has been lost entirely or degraded so it cannot support healthy runs as it once did. In addition, many juvenile Puget Sound salmon and steelhead do not make it through their first few months at sea. NOAA Fisheries researchers have further found that young Puget Sound Chinook salmon carry high levels of contaminants of emerging concern such as prescription drugs and antibacterial compounds, likely from local wastewater, at levels high enough to adversely affect their growth, reproduction, and behavior. It is critical that more of the regions efforts are focused on restoring Puget Sound Chinook salmon populations, given their importance to the SRKW diet.	The co-lead agencies agree with these findings and the CRSO EIS reflects these findings. Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the analysis in the CRSO EIS, which analyzes the effects of the operation, maintenance, and configuration of the CRS projects. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
4510	32	Kurt Miller	Northwest River Partners	The Role of Competition with Other Marine Mammals Since receiving federal protections, the population of seals and sea lions in the Northwest has exploded. A group of regional scientists estimate that these marine mammals have increased their consumption of salmon by up to nine times the historical amount.68 The increased competition from other marine mammals could potentially limit the availability of salmon for SRKW. Further, scientists found that Northern Resident killer whales, whose population is growing, may be directly outcompeting SRKW.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613.
4510	33	Kurt Miller	Northwest River Partners	he Role of Competition with Other Marine Mammals Since receiving federal protections, the population of seals and sea lions in the Northwest has exploded. A group of regional scientists estimate that these marine mammals have increased their consumption of salmon by up to nine times the historical amount.68 The increased competition from other marine mammals could potentially limit the availability of salmon for SRKW. Further, scientists found that Northern Resident killer whales, whose population is growing, may be directly outcompeting SRKW. The Role of Toxicity and Exposure to Pollution Human activity and development have had a direct and severe impact on the health of the Salish Sea and coastal waters of the Northwest. As a result, marine life has been negatively affected by pollution, toxic chemicals, and waste. Many of these pollutants and chemicals cannot be broken down or digested. Instead, they build up over time inside the living creatures that consume them. Through bioaccumulation, predators at the top of the food chain wind up with the most chemicals. One study found that salmon sampled from the Puget Sound contained 81 drugs and personal care products that included Prozac, Advil, Lipitor, and even cocaine.70 Additionally, the same study found high levels of contamination from human waste. A number of these toxic chemicals and pollutants are fat soluble, which means that they are stored in the fat cells. The SRKW population feeds almost entirely on fatty Chinook salmon, targeting the largest fish as referenced above. This means that SRKWs tend to accumulate extremely high levels of toxic chemicals and pollutants. Though the effects are not fully understood, there are two primary and widely accepted concerns: First, toxic chemicals and pollutants are passed to orca calves during their growth in the womb and after birth when they consume milk from their mother. Second, it is known that when food becomes scarce and orcas begin to burn fat, so the stored-up chemicals are released into their bloodstream. RiverPamters would like to summarize by saying that Southern Resident orcas desperately need and deserve the regions help. That said, the link between orca health and the existence of the LSRD is tenuous at best. A commonsense approach to improving orca health is to focus the regions efforts on improving the environment where the orcas spend the majority of their timein the Puget Sound and Salish Sea.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. 4510	34	Kurt Miller	Northwest River Partners	RESPONSES TO PRO-BREACHING REPORTS EnergyGPS Review of NWEC LSRD Replacement Study In 2018, the Northwest Energy Coalition (NWEC) released a theoretical studyproduced by Energy Strategiesthat indicated the LSRD could be cost-effectively and easily replaced, primarily by wind generation in Montana.72 The report relied largely on power supply assumptions from 2016. As mentioned above, since that time, the Northwest	The comment contains various concerns with the Northwest Energy Coalition (NWEC) lower Snake River dams power replacement study. The concerns voiced by this comment are largely consistent with the findings of the EIS. The EIS considered the NWEC study cited by the commenter, but finds that is not directly comparable with the EIS. This is for several reasons including that the EIS has a broader scope and relies on more recent regional load and resource availability and costs data, some of which is noted in the comment. See draft EIS, Section 3.7.3.1, Step 3 at page 3-820; Section 3.7.3.5, Related Study at page 3-913; and Appendix H, Power and Transmission, Section 2.4.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Power & Conservation Council, the Northwest Power Pool, and E3 have issued serious warnings over the possibility of regional blackouts. It is also noteworthy that Energy Strategies has updated many of its assumptions in a more recent analysis performed on behalf of Oregon, Washington, and several clean energy providers. In this updated analysis, Energy Strategies predicts an electricity capacity shortfall for the Northwest, even with the LSRD remaining in place.73 Despite the availability of updated information around coal plant retirements, people have continued to point to the NWEC study as proof that the LSRD arent necessary to the regions clean energy future. We believe it is potentially dangerous to rely on the NWEC-commissioned study determine the regions energy future, so we commissioned EnergyGPS, a leading energy consulting firm, to provide an analysis of NWECs 2018 report. The EnergyGPS critique demonstrates that the NWEC study was thorough but is based on questionable and dated assumptions that cast serious doubts on its conclusions. One example of a questionable assumption is that the studyin essencedouble counts the available transmission capacity freed up by coal plant retirements. The study assumes that the freed-up transmission will be used to import power to replace the LSRD. The study doesnt consider that the region will likely need those lines to replace the lost coal generation. This oversight means that incremental transmission would be needed to replace the energy from the dams. Transmission projects are both expensive and very difficult to site, which calls into question the viability of that plan. Importantly, the EnergyGPS analysis appropriately points out that we now live in a carbon-constrained world. The implication is thatgiven the legislative and political trends away from fossil fuelsit is likely not practicable to use coal or natural gas-fired power plants to replace the LSRD. Instead, if breached, the LSRD will have to be replaced by a carbon-free portfolio. Energy GPS forecasted that the least expensive combination of renewable generation and batteries would result in almost $1 billion in additional costs annually, which is very similar to the DEIS finding. Appendix 1 of this document includes the full EnergyGPS analysis of the NWEC study.	In addition, the EIS acknowledges the EnergyGPS study cited by the commenter in Appendix H, Section 2.4.5. The comparison of potential replacement costs up to $1 billion is also consistent with the findings of the EIS.
4510	35	Kurt Miller	Northwest River Partners	ECONorthwest Critique In 2019, Vulcan Inc. released the results of a report produced by ECONorthwest. The report indicated that the Northwest would receive economic gains by breaching the LSRD. Northwest RiverPartners reviewed the ECONorthwest report in-depth upon its release. We found that the report relied heavily on non-use value (i.e., a theoretical willingness of survey takers to pay) to reach its conclusion that breaching would provide an economic benefit to the region.74 The valuation was determined using a small survey, conducted by a dam breaching advocacy group. The survey question included language that guaranteed the restoration of wild salmon stocks if the dams were breached.75 It then asked how much the respondents would be willing to pay for that outcome. ECONorthwest took the average value provided by the respondents and multiplied across the populations of Northern California, Idaho, Montana, Oregon, and Washington to determine the theoretical non-use benefit. Despite its pro-breaching conclusion, the ECONorthwest report refers to extreme uncertainty around the potential benefits of dam breaching for salmon.76 This finding is a direct contradiction to the promise of guaranteed salmon restoration presented to the survey participants whose answers were used to calculate the non-use value. We believe that this contradiction, itself, invalidates the ECONorthwest analysis. The ECONorthwest analysis also notes that the population most likely to see a real benefit would be Snake River fall Chinooka species that is already a candidate for de-listing under the Endangered Species Act. Without the inclusion of non-use value, the report clearly shows a loss of around $2 billion dollars from breaching. Further, the report may have significantly overvalued its numbers on the recreational benefits of breaching by relying on studies with extremely limited sample sizes.79 Finally, in this section, we point to a separate study commissioned by the Pacific Northwest Waterways Association (PNWA). The PNWA study estimates an approximate net present value of $2 billion in harm to the region, just from the loss of barging, if the LSRD were breached.80 The study did not attempt to capture the costs of other impacts, such as the loss of hydroelectricity and irrigation.	Section 3.15.2.2 of the EIS describes the ECONorthwest study, highlighting the objective and approach to estimating willingness-to-pay for salmon restoration. Consistent with this comment, the EIS describes that the results of the study are designed to reflect the value people hold for restoring salmon populations, and therefore, have limited applicability to the benefits of the CRSO EIS alternatives. The Preferred Alternative provides substantial benefits to ESA-listed salmon and steelhead, which can make progress towards restoration or recovery; however, recovery targets are the responsibility of more entities than the co-lead agencies.
4510	36	Kurt Miller	Northwest River Partners	We caution the Action Agencies against adopting an alternative that increases spill beyond 115% TDG. We issue this caution due to the lack of solid scientific evidence showing higher spill levels lead to higher returns of adult salmonids. On the other hand, we note that scientific evidence does exist which shows spill levels which exceed 115% TDG can cause harm to both anadromous and resident fish. On this topic, we urge the Action Agencies to conduct explicit direct tests of the effect of high TDG levels on smolt survival in the river and, ideally, in the early marine phase after the smolts leave the river, where predators are abundant. The tests should be conducted with test and control groups. Such a test would be the most scientifically valid way to determine the effect of higher spills levels on SARs. Additionally, contingencies should be put in place to ensure that if higher spill results in negative impacts on salmonids or other native species of fish, that spill is decreased. The amount of the reduction should be determined based on further research into safe levels of TDG for the Columbia River System.	Tests as described by the commenter have been deemed as not necessary by the water quality agencies in the region. TDG levels are regulated under the Federal Clean Water Act, and administered by the States. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a 5-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. There is considerable uncertainty in the effects; and therefore, monitoring was required by the states and EPA to ensure any adverse effects are detected and allow for adaptive management. Migrating salmon and steelhead may spend sufficient time at depths that will compensate for the high gas levels. However, fish and other organisms that spend extended times in less than a few meters of depth are at high risk. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. Please see Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
4510	37	Kurt Miller	Northwest River Partners	Lastly, we encourage the action agencies to take additional steps to address the critical issue of avian predation. Such actions could have the greatest near-term improvements for struggling salmonid populations.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The Preferred Alternative includes a large suite of predation mitigation measures, some of which include maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative, which includes measures to reduce predation by avian predators, would provide benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The primary driver for these benefits to anadromous fish is increased spill during the juvenile fish migration.
4512	1	mayfair9897@gmail.com	N/A	First, as you well know, the Snake River Basin probably has the greatest potential for wild fish recovery of any watershed in the Columbia Basin. Due to having the coldest, most undisturbed stream habitat in the Basin, many scientists predict it will continue to hold the majority of cold water habitat as the climate warms. As a result, we need to open this premier spawning habitat to more wild salmon and steelhead, not continue to deny access, as has been the case for two generations.	The lower Snake River and lower Columiba River dams provide upstream passage. Chapters 4 and 7 include analysis of the climate effects to resources affected by Columbia River Systems (CRS) operations, maintenance and configuration. Sections 3.4 and 7.7.3 discuss water quality impacts in the lower Snake and lower Columbia rivers. Both human-caused and natural factors that are outside the responsibility and control of the co-lead agencies, also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat (see Chapters 6 and 7 for additional information). Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. The co-lead agencies acknowledge there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service website at: https://www.nwfsc.noaa.gov/research/index.cfm.
4512	2	mayfair9897@gmail.com	N/A	Second, decades of scientific research and study has consistently supported removing all four Lower Snake River dams to allow better and more access to pristine spawning habitat as the best and most important requirement to recover robust populations of wild salmon and steelhead in the Snake River basin. Recovery in the Snake River system will also enhance total salmon and steelhead stock in the Columbia River.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets certain objectives of the EIS for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend the measure to breach the four lower Snake River dams because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
4512	3	mayfair9897@gmail.com	N/A	Third, as with some previous versions of the DEIS, this one also makes the clear point that removing the lower Snake River dams is the best option for Snake River salmon and steelhead recovery. However, it appears that his DEIS woefully underestimates and downplays the benefits of removing the dams. In other words, the DEIS rightly and correctly concludes that removing the four Lower Snake River dams is the best alternative, it downplays that conclusion so that the DEIS can propose a worst alternative as being its "preferred" alternative. This is scientifically wrong. Next, having choses another inadequate plan as its "preferred alternative," this DEIS fails to adequately and scientifically document how this "preferred alternative" will either ensure increased numbers and quality of Snake River salmon and steelhead, this DEIS option fails to provide any reasonable assurance that its "preferred alternative" will even avoid extinction of some--or all!--Snake River salmon and steelhead. As a result, this DEIS will probably fail to meet the requirements of the Endangered Species Act, thus result in everyone going back in court to start yet another cycle of litigation for years to come.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative (PA) is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the PA also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the PA is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to salmon and steelhead impacts under the PA, the CSS model predicts that average Smolt-to-Adult return rates (SAR) will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the PA (increasing from 2.0% to 2.7% for Chinook, a 35% relative increase). Additionally, NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address the uncertainty due to the different model results, the PA includes working with regional sovereigns to develop a study that assesses the effectiveness of increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, and Total Dissolved Gas-related mortality of juvenile migrants.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The co-lead agencies invited a number of entities (including Tribes, states, and local agencies) from across the region to participate in the EIS process as cooperating agencies, and more than 30 of those invited agreed to participate. Staff from the cooperating agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation and configuration of the dams in the Columbia River Systerm (CRS). The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The draft EIS was subjected to two internal agency reviews by the Corps of Engineers experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available.
4512	4	mayfair9897@gmail.com	N/A	Also, for those who fail to see dam removal as a proven method to restore fish populations, look to recent success stories from Maine to the Olympic Peninsula of Washington State. The next dam removals will soon occur in the Klamath River basin, but we the people need action in the Snake River now.	Recent examples of successful dam removals are encouraging. However, these examples have little relevance to the lower Snake River Dams. For example, the Elwha dam had no fish passage. By contrast, the lower Snake River dams have up and downstream fish passage and provide economic benefits to the region by producing power; and providing for navigation and recreation. The four lower Snake River dams produce upwards of 1,000 aMW of power, which is approximately 12 percent of the average power produced by the Federal Columbia River Power System (FCRPS). See Draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. Losing this amount of power is equivalent to losing power capable of serving 730,000 homes in the Northwest. See Draft EIS, Section 3.7.3.5, Summary of Effect, page 9-935. The EIS finds that under the dam breach measure evaluated in MO3, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. Section 3.10 of the Draft EIS provides an evaluation of the Columbia Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, low air emissions relative to other transportation modes, potential regional economic, and other social effects that could occur under MO3. The lower Snake River projects currently support 2.6 million visitors and $24.5 million in social welfare value annually. Breaching the four lower Snake River dams would have both beneficial and adverse effects on recreation. Dam breach would preclude reservoir recreation during and shortly after the breach, eliminating reservoir recreation; over time, and as recreation areas and access are redeveloped by others, long-term beneficial effects to river recreation, including angling, are anticipated. Section 3.11 of the EIS describes that the visitation in the long-term in the lower Snake River would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), although not as much as MO3. However, the Preferred Alternative also meets certain objectives of the EIS for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not identify MO3 as the Preferred Alternative.
4518	1	Ellen_L_Saunders@me.com	N/A	The EIS is not taking into consideration the warming waters due to climate change.	The climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at the required resolution available at this time (river scale vs global or regional scale). Therefore, it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature and anadromous fish in Section 4.2.3 and 7.8.
4522	1	robert.zabrowski@jacobs.com	N/A	On October 22, 2019, a group of 55 leading scientists wrote a letter to policymakers in Washington, Idaho, and Oregon. The letter was titled: "Science-based solutions are needed to address increasingly lethal water temperatures in the lower Snake River." In this letter, our nation's experts on fisheries biology and water quality stated the issue very plainly: "Restoring the lower Snake River by removing its four federal dams will significantly reduce mainstem water temperatures on a long-term basis, and is likely the only action that can do so, substantially lowering the risk for salmon and steelhead here." This letter is just one of many, many examples of the state of the science-THE CONSENSUS- among our nation's experts on fisheries and water quality that the reomval of the four Lower Snake River dams is NECESSARY to recover robust and fishable populations of salmon and steelhead in the Snake River basin.	As required by NEPAs implementing regulations, the co-lead agencies used high quality information in the analysis of the CRSO EIS. In addition, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative (PA) is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the PA also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the PA is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase, Smolt-to-Adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River spring/summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SARs increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict that MO3 which includes the measure to breach the four lower Snake River dams is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The draft EIS was subjected to two internal agency reviews by the Corps of Engineers experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available.
4522	2	robert.zabrowski@jacobs.com	N/A	In reading through the draft CRSO EIS document (DEIS), it is abundantly clear that your (USACE, USBR, BPA) own analysis agrees that removing the 4 lower Snake dams, specifically Multiple Objective Alternative 3 (MO3), is far and away the best option for Snake River salmon and steelhead, not to mention the only alternative that includes meaningful reparations for the native people of this region. These four dams have contributed to abhorent devastation of social values, cultural values, and the food sovereignty of these tribes. The importance of the Snake River basin's anadromuos fisheries- from an ecological, social, cultural, and economic standpoint- cannot be understated. This leads me to one of the most frustrating aspects of the DEIS: it substantially underestimates the level of benefit from the removal of the 4 lower Snake River dams. From an Idahoan perspective, the economic analysis is embarassingly lacking. I urge you to review the analysis performed by the independent economic consulting firm ECONorthwest in 2019- "Lower Snake River Dams, Economic Tradeoffs of Removal" to see why the DEIS economic analysis of dam removal is unacceptable. To quote their executive summary: "The results of the analysis suggest that society will incur some costs from dam removal due to lost barge transportaiton and effects on grid services, but the public benefits relative to costs strongly justify removing the Lower Snake River Dams. In other words, the benefits of dam removal are large enough to fully compensate individuals or industries that could experience costs if the dams are removed." And what's so frustrating about the DEIS preferred alternative: it doesn't even provide reasonable assurance that it will avoid extinction, let alone recover our salmon and steelhead to abundant, harvestable levels. As a resident of the region, this in simply unacceptable. As a society, we've spent BILLIONS of dollars trying to recover these species over the past several decades without any significant results. Dam removal has proven to be the best method to restore fish populations.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies, also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. Section 3.15.2.2 of the EIS summarizes existing research regarding the publics willingness-to-pay for salmon conservation and restoration. This section specifically describes the ECONorthwest study referenced in this comment, highlighting the objective of the study and the approach to surveying rate payers to estimate willingness-to-pay for salmon restoration. The ECONorthwest analysis and the EIS employ different analytical frameworks and rely on different findings with respect to the outcomes of breaching the four lower Snake River dams. The findings of the ECONorthwest report that the benefits (of salmon restoration) outweigh the costs (increased power rates) of breaching the dams, rely on the implicit assumption that breaching will result in restoration of salmon populations. However, the fish effects analysis in Section 3.5 of the EIS does not find that MO3 would result in recovery of salmon or steelhead populations or restoring the populations to historical levels. Thus, the values presented in the ECONorthwest report should not be considered as representative of the benefits of MO3. The commenters suggestion that billions in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at Federal Columbia River Power System (FCRPS) projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act FCRPS 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
4523	1	bricehattel@gmail.com	N/A	The Draft EIS appropriately and correctly rejects alternative MO-3 which evaluated breaching of the Lower Snake River Dams and MO-4 which evaluated spill up to 125% TDG. Both of these alternatives would have extremely negative impacts on the hydropower system. MO-3 would more than double blackout risk in the region which is absolutely unacceptable. At this time of national emergency it is very difficult to imagine our customers trying to cope with a public health crisis with no power. An affordable and reliable power system is central to public health and welfare. Reducing power generation by 1,100 aMW of energy and elimination of over 2,000 MW of capacity under MO-3 is bad public policy and these extreme measures are not appropriate tools to assist salmon recovery. MO-4 is even worse with 1,300 aMW of lost generation coupled with 25% rate increases. As the economy slips into recession, these are unacceptable impacts on Montana ratepayers.	These comments are consistent with the EIS findings. See Draft EIS, Section 3.7.3.5 (MO3), Section 3.3.7.6 (MO4). Chapter 5 and Exhibit 1 of Appendix H, Power and Transmission provide additional details on potential rate increases by county as well as for urban and rural utility customers. The lost hydropower values cited are also consistent with the findings of the EIS with 1,100 aMW of hydropower generation and over 2,000 MW of sustained capacity lost under Multiple Objective alternative 3 (about 1,000 aMW attributed to breaching the four lower Snake River dams). For Multiple Objective alternative 4, the comment is consistent with the EIS findings that the reduction in system energy would be approximately 1,300 aMW and upwards of 25 percent of rate pressure. See Draft EIS, Section 3.7.3.6, Table 3-180, Table 3-182. The increased risk of power shortages, however, would only appear until adequate replacement resources are acquired. The cost of these replacement resources lead to the estimates of upward rate pressure.
4523	2	bricehattel@gmail.com	N/A	This leaves us with the Preferred Alternative which identified lamprey passage improvements plus adoption of a flexible spill program that would allow spill up to 125% TDG. We have very serious concerns about this operation which were identified directly in the Draft EIS. The Draft EIS acknowledges that this operation may actually reduce salmon survival by 7.5%! The loss of 160 aMW of generation on average while losing 300 aMW during low-water conditions does not represent an appropriate balancing of impacts for an operation that may end up killing more of the fish that it is intended to protect than the No-Action alternative. We have already seen a flexible spill operation in 2019 with spill up to 120% TDG that showed little benefit to fish with some evidence suggesting that survival was reduced.	The co-lead agencies used the current, high quality information in the analysis of the Draft EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model, which includes latent mortality effects, predicts that median Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address the uncertainty due to the different model results, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, and Total Dissolved Gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
4523	3	bricehattel@gmail.com	N/A	We do acknowledge that salmon and steelhead runs need support and assistance as these runs struggle to recover and tribes, sport and commercial fisherman and communities dependent upon salmon struggle, but the solution does not lie in destruction of the clean energy infrastructure of the Federal Columbia River Power System. The solutions lie in recognition that this is a Northwest-wide problem requiring significant change across the salmon life-cycle. People concerned about salmon are likely expecting far too much from an EIS limited to examination of operational changes for the federal hydrosystem when a comprehensive effort addressing Harvest, Hatcheries, Habitat and Hydro is required.	The co-lead agencies agree that salmon and steelhead are important resources in the Northwest and have invested substantial time and resources at the projects covered by this EIS to improve survival and adult returns. The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries website at: https://www.nwfsc.noaa.gov/research/index.cfm.
4524	1	N/A	N/A	I oppose breaching the Snake River damns because that action would eliminate an essential component of the Northwest's supply of clean hydroelectric power and increase the regions power costs by $1 billion annually and raise residential utility bills by 25 percent or more. This is in comparison to the estimated rate increase of 2.5 percent associated with increased spills for fish.	The comment about potential increases in electricity costs under Multiple Objective alternative 3, which includes the measure to breach the four lower Snake River dams, is consistent with the findings of the EIS. See Draft EIS, Section 3.7.3.5, Table 3-166.
4524	2	N/A	N/A	It will also place additional demands on existing road and rail infrastructure as well as at barging facilities near the Tri-Cities, thereby increasing CO2 emissions by 17 percent. And cost the U.S. $4 billion over the next 30 years due to the loss of barging. It will also drive up production costs associated with higher transportation costs for upriver movements (i.e., fertilizer, crops) thus imposing a greater financial burden on Washington's farmer's who are cost takers and have no way to pass the expense on.	The EIS assesses potential increases in CO2 emissions as well as increases in transportation costs in Section 3.10.3.5 of the EIS.
4526	1	stevenandlinda@msn.com	N/A	As your preliminary draft found, there is no real evidence that removal would improve the number of fish returning up the river. I believe it would do more harm than good. For example, the evidence regarding removal of the Elwah dam show very few fish have returned. I and many others believe that there is strong that the reason they have not many years returned is the release of silt from behind the dam. There is much more silt behind the four Snake river dams. That silt has many toxins that when released would cause much worse damage than was caused by the Elwah dam to the Elwah river.	Water quality effects from MO3, which includes breaching the four lower Snake River dams, are described in Section 3.4.3.6 of the Draft EIS, and sediment dynamics are analyzed in Section 3.3.3.5 (River Mechanics) of the Draft EIS. The EIS concluded MO3 would have greater improvement to certain salmon species in the lower Snake River. It did not conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Under the National Marine Fisheries Service (NMFS) COMPASS model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6 percent due to dam breach, which is a 19 percent relative increase over the No Action Alternative. The NMFS Lifecycle model predicts an increase in adult returns of 13.6 percent for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88 percent to 1 percent). Results for Snake River steelhead are similar (10 percent absolute improvement, or 23 percent relative juvenile survival increase; Smolt-to-Adult return rates (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River Spring/Summer Chinook is predicted to improve by 10.4 percent due to dam breach, which is an 18 percent relative increase over the No Action Alternative, while SARs would increase by 115 percent (from 2 percent to 4.2 percent). The CSS model also predicts that SARs increase by 177 percent (from 1.8 percent to 5 percent). Though differing in predictions, both models predict MO3 is the best CRSO EIS alternative for salmon and steelhead. Based on the EIS analysis the Preferred Alternative would make a substantial contribution to improving Snake River anadromous fish runs. With respect to the Preferred Alternative, the CSS model predicts that average SARs would increase for both Snake River spring Chinook and steelhead and would average above 2 percent (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the CRSO EIS for additional information.
4527	1	boyohboy41@aol.com	N/A	All of these states receive electricity that is generated by these dams. These dams have prevent flooding which was a major factor before the dams were built. Central Washington State relies upon the irrigation water for agriculture--this part of Washington State is the only true desert in the state and the water has made irrigated farm products an extremely important form of economic income for the state. These dams allow ships/barges/water craft to navigate the entire distance from the Pacific Ocean to Lewiston Idaho/Clarkston Washington. The farm commodities are shipped on this system of rivers to ports closer to the Pacific Ocean to be shipped to our international partner countries. This form of transportation is much less expensive than using rail service or trucks. People who advocate the removal of these dams are totally ignorant of the economic importance of these dams. They are obviously unaware of the negative effects that would happen should these dams be removed from the rivers. There is NO WAY to provide the amount of irrigation water that is provided by the these dams. There is no economically feasible way to provide the electric power that is generated by these dams should they be removed. It is totally obvious that those who are promoting the removal of the dams have NO knowledge of the history of the states in the Pacific Northwest. They also have NO knowledge of the geography of the Pacific Northwest. One example is that the aluminum industry located in Washington State during the Second World War because the low cost electric energy was available for their factories and they were able to use the aluminum for airplanes needed during the war effort. Any plan to remove the dams on the Snake and Columbia Rivers would have a horribly negative effect on the economy of the Pacific Northwest.	As described in Section 3.10.3.5, Navigation and Transportation analysis for MO3, the EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are double, depending on their specific location and other conditions. As described in Section 3.12.3, Environmental Consequences for Water Supply, engineering solutions, such as pipeline extensions and/or modifying existing pump system would be cost prohibitive. Additional details are provided in Appendix N. In Region C under MO3, this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres, as discussed in Section 3.12.3.
4529	1	N/A	N/A	I would implore you to seek the preferred alternative that does not include breaching the critically important hydroelectric & navigation structure on this river system. Additionally, I would ask you to not seek additional spills as an option, with the many realized costs this would originate. Higher spill rates are counter to the intent of the proposal for fish survival rates. Higher nitrogen rates due to higher spill rates will instead cause higher mortality rates in the very fish populations we are trying to see stabilized growth in.	The co-lead agencies did not recommend the measure to breach the four lower Snake River dams that is included in MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies used high quality information in the analysis of the EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model, which includes latent mortality effects, predicts that median Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of the Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be for increasing salmon and steelhead returns to the Columbia Basin. This monitoring program will include substantial monitoring efforts to track the effects of dissolved gas levels on juvenile and adult fish. To address the uncertainty due to the different model results, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, and Total Dissolved Gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
4529	2	N/A	N/A	Additionally, higher spill rates are expensive in flushing thousands of dollars of potential energy stores downstream without retrieving any transfer of energy from them in the process. This would dramatically increase electricity rates in the Northwest and have a devastating impact on business, from small business owners all the way up to corporations who need the less-expensive power rates to bring raw and polished goods to market at a competitive price.	The comment that higher spill would increase regional electricity rate pressure is consistent with findings of the EIS. The Environmental Justice analysis in Section 3.18.3 of the EIS provides further detail on potential disproportionate effects to tribal, low-income and minority populations.
4551	1	bicycle81@yahoo.com	N/A	1) The Draft EIS must profoundly consider the long-term probable effects of climate change on river temperatures, flow, water quality, and salmon.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia Basin in still under development and was not available for this EIS. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, there are not reliable models at the resolution required (river-scale vs. global or regional scale) at this time. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapters 4 and 7).
4551	2	bicycle81@yahoo.com	N/A	2) Steelhead have come back extraordinarily strongly after dam removal in the Elwha River. Dam breaching very likely offers the best chance to save steelhead based on Elwha experience, and may do the same for salmon.	The EIS studied breaching the four lower Snake River dams as part of MO3. Many dam removal projects that have occurred across the United States have very different circumstances than what is contemplated in MO3. The commenter is correct regarding Elwha dam in Washington State; however, this example has little relevance to the lower Snake River dams. The Elwha dam had no fish passage and provided no economic benefits. In contrast, the four lower Snake River dams provide upstream and downstream fish passage, produce power, and provide navigation and recreation opportunities. For power, the four lower Snake River dams produce upwards of 1,000 aMW of power, which is approximately 12 percent of the average power produced by the Federal Columbia River Power System. See Draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. Losing this amount of power is equivalent to losing power capable of serving 730,000 homes in the Northwest. See Draft EIS, Section 3.7.3.5, Summary of Effects, page 9-935. The four lower Snake River dams would still have regulated flows due to the dams located upstream.
4551	3	bicycle81@yahoo.com	N/A	3) A free flowing Snake River will supercharge the existing recreational mecca, benefitting struggling rural economies along the river. The agencies must evaluate local economic benefits in the Final EIS.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
4551	4	bicycle81@yahoo.com	N/A	5) The impacts of future irrigation withdrawals from the lower Snake are likely to feel pressure to increase due to climate change. The Klamath River had environmental struggles between fish and irrigation. This clouds the future of the Snake under the draft EIS incompleteness.	Warming temperatures could lead to increased evapotranspiration, which could increase irrigators need for water. Section 6.3.1.12 describes the potential cumulative effects of continued water withdrawals. The EIS did not identify any specific reasonably foreseeable additional future withdrawals to analyze.
4551	5	bicycle81@yahoo.com	N/A	6) The Final EIS must include consideration of fish passage and reintroduction above Grand Coulee and Chief Joseph dams to support tribal fishery restoration goals in the Upper Columbia.	Measures to reintroduce salmon above Grand Coulee and Chief Joseph were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, Federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the Columbia River System, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps.
4551	6	bicycle81@yahoo.com	N/A	7) The Final EIS must consider the proper context for addressing the benefits and costs of the Columbia-Snake hydropower system, which means properly addressing the enormous costs - past, present, and future - to the tribes within the basin from the loss and eventual extinction of salmon and steelhead.	The EIS recognizes the economic and cultural importance of salmon to tribes in a number of sections throughout the document. The Fisheries Section 3.15 as well as Section 3.17, in particular, include discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries Section 3.15.2.1, which includes sub-sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries. Section 6.3.1.5 examines the cumulative effects to fisheries resources.
4552	1	N/A	N/A	*The Draft EIS is deeply flawed because it did not complete the analysis of the effects of climate change on river temperatures and salmon.	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia River Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology would affect reservoir operations in the Columbia Basin in still under development and was not available for use in this EIS. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, there are not reliable models at the required resolution (river-scale vs. global or regional scale) at this time. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitative assess potential effects to resources (described in Chapters 4 and 7).
4552	2	N/A	N/A	*Dam breaching offers the best chance to save salmon and steelhead. *Breaching and restoring the lower Snake to a free flowing recreational mecca will provide enormous economic activity for struggling rural economies.The agencies must evaluate these benefits in the Final EIS.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. The EIS evaluates the performance of the CRSO EIS alternatives with respect to multiple stated objectives, for example related to improving fish passage and survival, providing reliable power generation, and minimizing greenhouse gas emissions. The measures in the Preferred Alternative were determined to meet the Purpose and Need Statement of the project while also minimizing environmental, economic, and social impacts (see Table 7-1 in the Draft EIS). For example, the EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which are described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region.
4552	3	N/A	N/A	*The Final EIS must include a basin-wide review of flood risk management and how the 2024 expiration of the coordinated flood control operations under the U.S.-Canada Columbia River Treaty will impact storage and flows in the Columbia and Snake.	Section 3.9 of the EIS analyzes flood risk management effects from each of the Multiple Objective alternatives. The effects of the Preferred Alternative on flood risk management are described in Section 7.7.11. Section 2.4, Range of Alternatives, provides a brief discussion of the Columbia River Treaty. The 2016 Treaty-related operations, were applied in the EIS analysis, as the best-available information. No significant changes from the 2016 Treaty-related operations occured during this EIS so no changes were included in the Final EIS.
4552	4	N/A	N/A	*The Final EIS must consider the impacts of future irrigation withdrawals, from the lower Snake, which are likely to increase due to climate change.	Warming temperatures could lead to increased evapotranspiration, which could increase irrigators need for water. Section 6.3.1.12 describes the potential cumulative effects of continued water withdrawals. The EIS did not identify any specific reasonably foreseeable additional future withdrawals to analyze.
4552	5	N/A	N/A	*The Final EIS must include consideration of fish passage and reintroduction above Grand Coulee and Chief Joseph dams to support tribal fishery restoration goals in the Upper Columbia.	Measures to reintroduce salmon above Grand Coulee and Chief Joseph were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, Federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the Columbia River System, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps.
4552	6	N/A	N/A	*The Final EIS must consider the proper context for addressing the benefits and costs of the Columbia-Snake hydropower system, which means properly addressing the enormous costs - past, present, and future - to the tribes within the basin from the loss and eventual extinction of salmon and steelhead. I	The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The Fisheries Section 3.15 as well as Section 3.17, in particular, include discussion of reductions in anadromous species catch and associated adverse social effects that have occurred in tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries Section 3.15.2.1, which includes sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries. Section 6.3.1.5 of Chapter 6 and Section 7.9.18 of Chapter 7 examines the cumulative effects to fisheries, and Section 7.7.17 describes the effects of the Preferred Alternative on fisheries.
4555	1	N/A	N/A	Furthermore, as trustee for a 68,000 plus member cooperative AND as a landlord with tenants in a lower wage earners area, access and cost of wholesale energy and therefore cost of retail electricity is an absolutely critical aspect of this necessary commodity. Recent growth and spiking housing costs in this area have put many on the edge of affording housing. Indeed, the additional cost of electricity makes purchasing or renting a home daunting challenge. Unfortunately, some, or even many, are homeless in my area and since all housing includes an electric bill above the actual rental bill that cost is critical. Therefore, cost, availability and reliability of electricity is of critical importance to all. I can mention further, even more so in Montana winters. It was in Montana that the lowest recorded temperature in the continental 48 United States was recorded at 69* below zero. That recording was made at Rogers Pass, Montana, in winter of 1953-54. So cold was that temperature, the thermometer was sent to D.C. to be tested. It was found to be accurate. Lower temperatures and a failed electrical supply or grid along the I-5 corridor is indeed an unfortunate and inconvenient issue, but in the aforementioned Montana temperatures, it can easily be life or death. Perhaps even more so today than in 1954, because today, your modern efficient gas furnace will not fire without first the purge cycle evacuating possible latent gas, nor will the piezoelectric igniter spark to ignite the heat producing burning gas. A long mid- winter reliability issue is not an inconvenience, it can be a broad life-threatening experience for both gas and electrically heated homes which heats most Montana homes. Affordable, accessible, and reliable electricity is not a luxury, it is an absolute modern necessity. Furthermore, though reliability issues can occur randomly, the probability of a reliability issue increases exponentially in these times of higher usage and system stresses. I mention this in support of the necessity of keeping and maintaining the operation of the four Lower Snake River Dams (LSRD). These dams are critical today- and in a world of disappearing coal plants, the social undesirability of NEW Nuclear plants, emerging carbon emission legislation in our Northwest region, and frankly, the frightening emerging future reliability figures being seen, coupled with the possible cost aspects of having reliable electricity available in forward years make these LSRD far more critical in our future years. Everybody needs access to affordable reliable electricity. One can state the issue is even more insistent due to our past years of real efforts in efficiency and conservation practices in our region. Having done so much of that in our recent past will make it much more difficult and to accomplish those same goals in our future as the easier methods are done first and the difficult done last.	As explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are connected to Automatic Generating Control (AGC), making them among the few projects that are capable of providing balancing reserves. See Draft EIS, Section 3.7.3.5, Value of Lower Snake River Dam Ramping Capability. The four lower Snake River dams currently carry approximately 20 percent of upward flexibility and 8 percent of the downward flexibility held by the Federal Columbia River Power System for balancing reserves. Replacing hydropower with solar and wind does not replace the dispatchable characteristics of the four lower Snake River dams. Indeed, the EIS found that the demand for the dispatchable capability of the four lower Snake River dams would increase as the need for balancing reserves grows to integrate additional wind and solar in the region. See Draft EIS, Section 3.7.3.5, Integration Services, page 3-832.
4555	2	N/A	N/A	These Lower Snake River Dams (LSRDs) with their 2000 MGW of quick response continuous load following availability are needed today and will be more sorely needed in our carbon restrained future of disappearing out of vogue resources. Some of our own co-operative members have spoken with me about emerging renewables. To each of them I have responded, in truth, how renewables have a great role to play today and in our future. But, when you have to have that electricity, like on a calm cold well below Zero winters night, after the storm has passed and the cold below zero temperature air mass has settled in for however many days to come, you are now stuck with a stark reality of intermittent resourced electricity as your depending supplier. Because the wind does not blow after the cold air mass has settled in. Also, the sun is not shining on that cold winters night, nor can it dependably shine enough of those few hours of sun the next day to reliably carry you through. At those times of future real reliability deficits, null or	The EIS describes how this dispatchability is essential to providing balancing reserves, which is used to meet system uncertainty and to integrate renewable resources, such as wind and solar. See Draft EIS, Section 3.7.2.2, Meeting System Uncertainty with Generation Balancing Reserves, Dispatchable Resources, and Ramping Capability. The Preferred Alternative does not include the measure to breach the four lower Snake River dams that was analyzed in Multiple Objective alternative 3.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				low capacity renewables may not only fail to provide, but actually exacerbate the problem because of no production at those most critical times. However, if we have unfreezable water from deep reservoirs behind a Hydroelectric dam we in essence already have the longest lived most dependable battery to get us through. Deepwater hydroelectric dams are truly the largest, continuously charged, long duration huge battery bank you can or will find for long time coming. AND, unbelievably, reliable and affordable enough even our low wage-earning fellow citizens can purchase that electricity. We all see the ubiquitous use of electricity around us. The rank and file of us who take it for granted, those who struggle in their need to keep the lights and, probably more importantly, also the heat on, and even seeing the summer irrigation producing the more copious and therefore more affordable foods we purchase. And, yes, all battery and renewable technology have a place. As such, hydroelectric dams are just the best batteries society has and they are the epitome of renewal and reliable. It would be folly to abandon them in such a future of questionable reliability.	
4555	3	N/A	N/A	That said, I do also consider the aquatic species survival aspect of these rivers as important. However, I do believe it could be a hugely complex and open question whether these Hydro-electric dams are causal in issues of inability of getting historic fish runs. I do also hear the survival rate of salmon in the FCRPS is very similar to dam free rivers. Meanwhile to expect historic fish runs might be unrealistic. Or certainly blaming the dams specifically is truly a myopic response. How many other factors are causal? How many millions of acres of suburban sprawl replete with manicured lawns with continued applications of herbicides and pesticides and unshaded or lost spawning streams have a possibly greater impact? Is it not possible these and the other multitude(s) of factors so complex with the modern complexities of current vast populations of humans with human needs juxtaposed to an earlier era vastly different are our issue. That seems an unsolvable conundrum to me. Much easier to point to a large concrete structure, but certainly far from the real historic runs truth. Looking through aspects of the CRSO DEIS, I do believe it was correct to negate the LSRD breeching studies as too societally costly and with little improvement for the aquatic specie(s) aspect. I believe that was the given charge of the CRSO: to weigh in a reasoned fashion the impact of these dams and how to best serve the modern needs which have evolved in todays world for the best benefit of all species-humans included.	The scope of the Draft EIS focuses on the area affected by the alternatives presented for operation, maintenance and configuration of the Columbia River System projects. There are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service website at: https://www.nwfsc.noaa.gov/research/index.cfm. Section 3.5 of the EIS provides the analysis of the effects to fish under each of the Multiple Objective alternatives and Chapter 7 describes the impacts to fish under the Preferred Alternative.
4555	4	N/A	N/A	I do support the Preferred Alternative, but with a caveat of following tracking to determine if the the higher 125% TDG aspect of this approach might be harmful than helpful to in river salmon and steelhead. If it does appear more harmful than helpful, I would support a lower spill regime with lower TDG levels as a better approach for both fish and power cost and increased reliability purposes.	The Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, and Total Dissolved Gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
4571	1	N/A	N/A	The lakes the dams create preserve fire fighting capability for mega fires that can happen in the region. California had huge fires in 2019 and could not begin to control them. Its not the 1800s anymore. We will need bigger solutions to bigger problems. Its only a matter of time. What will populations be in 2100? What will fire issues be like?	Section 3.10 in the EIS has been revised to acknowledge that the reservoirs are used, or are capable of being used, for firefighting purposes. It is acknowledged that this use would be made more difficult following the breach of the four lower Snake River dams under MO3 due to reduced water depths and area.
4571	2	N/A	N/A	Increase pumping costs that would result in lower net farm income across the region, which translates to farm households having less money to spend within the regional economy as well as put pressures on other resources.	The effects of the increased pumping costs are included in the economic analysis described in Section 3.12.
4571	3	N/A	N/A	FURTHER IT WILL REQUIRE OTHER METHODS OF TRANSPORTATION THAT ARE LESS CLEAN. It will over burden roads and cost more dollars in other places to deal with NEW PROBLEMS. Residential drivers don't need more truck traffic.	The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. There would need to be investments in infrastructure if dams are breached, both public and private sector investment in the absence of river navigation. These infrastructure improvements are discussed in section 3.10 of the EIS.
4571	4	N/A	N/A	HISTORY: The "Great Flood of 1894" was the highest-recorded flood along the Columbia of all time. Rainfall was heavy during the winter of 1893-94 resulting in a heavy snowpack. A dry and warm spring resulted in massive snowmelt. Peaks reached nearly 35 feet at Umatilla, Oregon, and Longview, Washington hit a record 24.0 feet (12 feet over flood stage). A measured peak at The Dalles was 1,240,000 cubic feet per second (enough flow to cover a standard-size football field with water 1,500 feet deep in just one minute) while flood stage on the Willamette River at Portland, Oregon was measured at 33.0 feet. The town of Cascades, located near the location of today's Bonneville Dam, was wiped out. That is not even a 500 year event. REMEMBER HISTORY AS HISTORY CAN REPEAT AND HUMANS WILL SUFFER.	Section 3.9 of the EIS analyzes flood risk management effects from each of the Multiple Objective alternatives within the CRSO study area. The effects of the Preferred Alternative on flood risk management are described in Section 7.7.11
4572	2	alvestadlaw@gmail.com	N/A	And while I make these comments based upon my near 20 year involvement in the industry and concern for PLC's members and the environment, I also am personally concerned that the alternatives do not adequately address shipping and navigation. I fear that carbon based cargo delivery alternatives will contribute even more to the environmental burden and burden on agriculture.	Section 3.10 of the EIS evaluates potential effects of MO3 on emissions due to shifts from use of barge shipping through the lower Snake River dams to road and rail transportation. The analysis does anticipate an increase in truck and rail transportation, and associated CO2 emissions, under MO3 relative to the No Action Alternative. Specifically, MO3 increases CO2 emissions by up to 0.06 MMT CO2.
4572	3	alvestadlaw@gmail.com	N/A	Peninsula Light Company supports the D-EIS Preferred Alternative option proposed by the co-lead agencies	Thank you for your comment.
4579	1	Ryan Poe	Washington Association of Wheat Growers	WAWG represent thousands of farmers across Eastern Washington and farm landowners throughout the region. We strongly support the Congressionally mandated multi-use functions of the Columbia-Snake River System and the preferred alternative brought forth in the EIS that rejects dam breaching measures as part of Multiple Objective Alternative 3.	Thank you for your comment.
4579	2	Ryan Poe	Washington Association of Wheat Growers	Without barging, the EIS estimates a 33% transportation cost increase. But with many factors at play, such as additional truck purchases that might be required in order to move grain further; freight rate increases; fuel, rail and road improvement expenses; and more that will assuredly be passed on to the farmer, we contend the increased cost to be much higher and request that the final EIS be updated to include these specific costs, including transition costs, that would be associated with no navigation on the lower Snake River.	The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. The EIS finds that those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted.
4579	3	Ryan Poe	Washington Association of Wheat Growers	Even though I move most of my wheat on the rails, not on the river, the loss of barging as a transportation option will still impact my bottom line. Without the competition, rail rates are likely to rise, making it more expensive for me to ship my wheat. And as more wheat is pushed onto the rails, availability may become an issue, leaving me with no way to ship my wheat or having to deal with significant shipping delays, which will incur additional storage expenses	The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted. The EIS recognizes that there is no guarantee wheat grown in the Northwest would be competitive now or in the future because there are many factors that influence international commodity markets (e.g., trade agreements, the U.S. dollar, global supply, etc.). However, the analysis finds that the cost to transport wheat to market would continue to be lower than costs paid by other wheat growers in the United States (e.g., the Dakotas and Midwest). Favorable conditions for Northwest wheat growers that help them stay competitive are: (1) the natural environment of the Palouse region (weather, soils) is ideal for growing this type of wheat, which leads to some of the highest yields per acre in the world, and (2) proximity of Northwest export ports. Currently, the cost to transport wheat to market is quite low relative to other parts of the United States and world. Environmental and human health impacts associated with increased emissions to shipping goods by rail or truck (or both) are evaluated and described in Section 3.8 Air Quality, and increased health and safety concerns due to increased truck traffic on roadways and potential for increased accidents are described in the Navigation and Transportation Section for other social effects (Section 3.10.3.5).
4579	4	Ryan Poe	Washington Association of Wheat Growers	In the case of transportation, the river truly does flow in two directions. We request that the final EIS include the costs of lost barge service on all of the freight moving on the river, not just wheat moving downriver. At the same time, it must be recognized and accounted for in the final EIS, that rail rates throughout the Northwest for all commodities will rise as capacity is constrained.	In 2018, 72 percent of overall freight volume on the lower Snake River system traveled downriver, the majority of which (87 percent) was wheat and barley. As discussed in Section 3.10.2.1 of the Draft EIS, 28 percent of overall freight traveled upriver. In 2018, 25 percent of overall freight on the lower Snake River was petroleum products that terminated below Ice Harbor Dam. These shipments that do not utilize the Snake River locks would not be directly affected by dam breach under MO3. Other commodities that utilize the Snake River system include pulp and paper products (4 percent) as well as chemicals and iron/steel commodities (8.5 percent), some of which also terminate below Ice Harbor Dam. To the extent that these shipments utilize the Snake River locks and dams, they would be affected under MO3 by increased transportation costs. These potential effects are discussed qualitatively in Section 3.10.3.5. MO3 was not identified as the Preferred Alternative.
4582	1	N/A	N/A	Finally, regarding the consideration of the various replacement portfolios in the context of this EIS. It is unclear whether the co-lead agencies have the authority to acquire replacement resources under an MO3 Alternative (or any other MO that may require resource acquisition). We recommend further study of this issue between the Draft EIS and the final Record of Decision.	The EIS acknowledges that any acquisition of resources would require additional site specific environmental compliance, including NEPA analyses, permitting and a potential statutory process to allow Bonneville to acquire resources. Section 3(1) of the Northwest Power Act states that the Bonneville Administrator is not authorized to construct, or have ownership of, any electric generating facility. Section 3.7.3.1 Methodology, Step 3: Determine Need for Potential Replacement Resources in the draft EIS provides additional detail. Bonneville may acquire the output of a major resource, provided that such acquisitions follow certain statutory requirements as set forth in Section 6 of the Northwest Power Act. Appendix H, Section 2.2.4 in the Final EIS discusses the process for potentially acquiring new resources.
4582	2	N/A	N/A	one of our concerns with the Draft EISs analysis under all of the Multiple Objective Alternatives, not just MO3, is the vastly divergent range of scientific results between the federal governments National Marine Fisheries Service (NMFS) in its Life Cycle Model (LCM), and the Fish Passage Centers Comparative Survival Study (CSS) model. The disparate range of outcomes between the two bodies of science is particularly apparent when it comes to latent mortality, the delayed death of salmon following passage through the Columbia River System. Indeed, the co-leads analysis concluded that, The degree to which latent mortality is affecting salmon and steelhead is one of the critical uncertainties in this EIS analysis (ES, Page 25). This is a significant concern that we fear will continue to be a roadblock to durable consensus around Columbia River System Operations. We understand the significant challenges associated with resolving the divergent bodies of science presented in the Draft EIS, but encourage the co-lead agencies to work toward identifying additional sources of scientific expertise that can provide independent, objective advice such as the National Academy of Sciences.	The NMFS COMPASS and Life Cycle models and the CSS models use different statistical approaches and input variables. Both are able to provide a good fit to recent survival, and travel time estimates, but the models do have substantially contrasting forecasts for these metrics under hypothetical scenarios of CRS operation with respect to flow and spill. The Fish Technical Teams for the CRSO EIS made the decision to present results from both sets of models for the final evaluation, along with descriptions of methods. Many aspects of the Draft EIS analysis, including the Life Cycle model and CSS models, will undergo an independent external peer review before being finalized. The framework for the adaptive management process is detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, tribal, and federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. The Preferred Alternative will require a robust monitoring plan for salmon and steelhead to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin.
4582	3	N/A	N/A	From a reliability perspective, under MO4, the increase in spill (i.e. 125% TDG, 7 days a week, 24 hours a day from March 1 to August 31), together with a measure that provides dry-year augmentation of spring flow with water stored in upper basin reservoirs, was found to have the highest probability of power shortages of any of the MOs, with blackouts or emergency conditions in roughly one in three years (ES, Page 30). We know blackouts carry dire socio-economic impacts, and encourage the co-leads to further study the true effects of outage-related disruption.	The statement that the loss of hydropower under MO4 results in the largest reliability effects is consistent with the findings of the EIS. The EIS estimates the costs of replacement power and transmission resources needed to avoid increasing the risk of an outage, rather than estimating the costs of increased outage occurrence. Quantifying both the costs of restoring system reliability and the costs of outage events under the alternatives would risk double counting potential impacts. See Section 3.7.3.1 Methodology and Chapter 2 of Appendix H for additional details on the EIS approach to evaluating power system reliability and potential replacement resources and costs.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
4582	4	N/A	N/A	For BPAs wholesale power rates, MO4 places upward base rate pressure of 23.5 percent to 25.3 percent over the No Action Alternative depending on the type of resources acquired and the source of funding for those resources. Additional rate sensitivities around this base analysis . . . could lead to upward rate pressure as high as 41 percent in the Bonneville wholesale power rate (ES, Page 30). For all of the reasons described previously, our rural cooperative members simply cannot tolerate these rate increases.	Juvenile fish passage spill to 125% Total Dissolved Gas from March through August at the four lower Snake River and four lower Columbia River projects was evaluated in Multiple Objective 4 (MO4) but was not included in the Preferred Alternative identified in the EIS. The rate pressures identified in the comment are consistent with the findings of the MO4 in the EIS. Section 3.7.3.6, Electricity Rate Pressure, at pages 3-945-950, Table 3-182, in the Draft EIS. MO4 did not meet the EIS objective of providing an adequate, economical, efficient and reliable power supply, among others, and was thus not identified as the Preferred Alternative. See Section 7.3.5, Multiple Objective Alternative 4, at pages 7-13-15, in the Draft EIS. For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control.
4582	5	N/A	N/A	PNGC finds that the NWEC analysis, along with similar studies, tends to assume-away transmission limitations on the Northwest grid. The co-leads addressed transmission limitations in the Draft EIS, however as described below, PNGC thinks further analysis is necessary in the final EIS.	The Northwest Energy Coalition analysis is discussed in Section 3.7.3.5, Related Studies. The EIS analysis included multiple transmission models to assess power flows, grid congestion, and to determine transmission costs as described in Section 3.7.3.1, Methodology in the Draft EIS. In order to perform the dynamic stability analysis, site-specific and resource-specific details for each replacement generator (such as manufacturers, control systems, precise placement locations, etc.) would need to be determined. The EIS examined the feasibility of potential replacement resources, but the methods used did not speculate as to the exact details for each resource. It is unnecessary and would be premature to perform a more complete analysis of the replacement resources until those details are known. That information would be evaluated in subsequent planning processes.
4582	6	N/A	N/A	Table 3-6 of Appendix H, summarizes the potential total energy above limit due to congestion on transmission lines if the LSRDs are removed for the Tri-Cities area. It is important to convert this vague language to plain language. This is what the Tri-Cities area can expect in the event of a possible blackout. We do not think the Draft EIS adequately converts technical impacts into real-world, socio-economic impacts. We encourage the federal agencies to perform analysis on this as suggested in our comments below on socio-economic impacts. Our preliminary assessment is that the social cost of these blackouts could be in the tens of millions of dollars per-year based on the total energy above limit figures in Table 3-6 of the Draft EIS.	The EIS analysis evaluates the costs of replacement resource portfolios including the necessary transmission interconnections and reinforcements that would be required to avoid increasing the risk of an outage. Given this, the analysis identifies that the expected outcome of MO3, which includes breaching the four lower Snake River dams, would be an increase in the cost of power and not in the risk of an outage. In the Draft EIS, please see Section 3.7.3.5, at pages 3-918-924; and Table 3-166. In the Draft EIS, Appendix H, Section 3.2.2, Bonneville Network Reinforcement Needs, describes the reinforcement of a 20-mile transmission line costing $94 million in capital costs to address the risks in the Tri-Cities area in Washington. These costs are included in the transmission rate pressures described in Section 4.2 and then factored into the retail rates analyzed in the Social and Economic Effects described in Chapter 5 of Appendix H.
4582	7	N/A	N/A	One of PNGCs most significant concerns about the transmission analysis is related to what has not been performed versus what has actually been performed. Based on the data and results presented in the Draft EIS, it appears that extensive power flow analysis has been performed to identify transmission limitations and impacts of the alternatives. However, it does not appear that dynamic stability analysis has been analyzed to adequately assess whether the replacement resource portfolios will perform adequately during contingency events and transmission outages.	In order to perform the dynamic stability analysis referred to in the comment, site-specific and resource-specific details, including: manufacturers, control systems, and precise placement locations for each replacement generator would need to be determined. The EIS examined the feasibility of potential replacement resources, but the methods used did not speculate as to the exact details for each resource. It is unnecessary and would be premature to perform a more complete analysis of the replacement resources until those details are known. That information would be evaluated in subsequent planning processes.
4582	8	N/A	N/A	Again, it is critical to translate this complex narrative into plain language. What this means is that we are not really sure the replacement resources will perform under system disturbance events, and we could see additional blackouts. Therefore, we encourage the federal agencies to work with organizations such as WECC to perform additional dynamic stability studies to assess how the replacement portfolios perform compared to the hydropower units among the various alternatives considered by the Draft EIS.	The measure to breach the four lower Snake River dams that was evaluated in MO3, was not included in the Preferred Alternative identified in the Draft EIS. The effects of the Preferred Alternative (PA) on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the PA. However, because of the shape of the remaining hydropower generation in the PA, the loss of load probability (LOLP) was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary. The transmission analysis is not an exhaustive examination of all reliability requirements of the system under the assumed replacement resources. Rather, the EIS assessment examined whether the identified set of resources to replace the generation removed under the various Multiple Objective alternatives (MOs) might reasonably be able to restore the LOLP to a comparable level as the No Action. In the Draft EIS, see Section 3.7.3.5, Effects on Power System Reliability, at page 3-903; and Appendix H, Table 2-1. Much more detail and certainty about the replacement resources would be needed to provide the certainty suggested by the commenter and is not necessary for informed decision-making. In order to perform the dynamic stability analysis referred to in the comment, site-specific and resource-specific details, such as manufacturers, control systems, precise placement locations for each replacement generator would need to be determined. The EIS examined the feasibility of potential replacement resources, but the methods used did not speculate as to the exact details for each resource. It is unnecessary and would be premature to perform a more complete analysis of the replacement resources until those details are known. That information would be evaluated in a subsequent planning process.
4582	9	N/A	N/A	While we generally agree with and appreciate the Draft EISs careful and comprehensive review of related studies as well as development of new federal studies and analysis on which the Preferred Alternative was developed, we think the final EIS must address some open and uncertain issues as described above. The Draft EIS does a reasonable job of beginning to capture the full scope and scale of the value of the LSRDs and the federal hydropower system in general in the Northwest in terms of electric system reliability. However, it leaves open or unaddressed the uncertainty and issues created particularly by MO3 and MO4.	The EIS relies on high-quality information regarding replacement resources, transmission system reliability and the Northwest power system from a variety of data and information sources. Although it would be beyond the scope of the EIS to capture all possible sources of uncertainty, some of the uncertainty surrounding replacement resources are addressed either quantitatively or qualitatively in the EIS, particularly surrounding environmental compliance, permitting, location, and the effect of ongoing policy developments and coal power plant closures on replacement resources. In the Draft EIS, see section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, page 3-821.
4582	10	N/A	N/A	With respect to the proposed replacement portfolios studied in MO3 and MO4, it is imperative that the federal agencies further analyze both the potential socio-economic implications of substantial increases in LOLP, as well as the degree of confidence in whether the studied replacement resources perform sufficiently to mitigate the increases in LOLP as well as the transmission issues described above.	The EIS estimates the costs of replacement power resources and transmission infrastructure needed to avoid increasing the risk of an outage, rather than estimating the costs of increased outage occurrence. Section 3.7.3.1, Base Case Methodology, at pages 3-819-21, 3-822-23 in the Draft EIS. Quantifying both the costs of restoring system reliability and the costs of outage events under the alternatives would risk double-counting potential impacts. The EIS uses the Northwest Power and Conservation Council GENESYS model to analyze loss of load probability as well as a variety of industry standard models to assess the performance of potential replacement resource portfolios. See Section 3.7.3.1 Methodology and Chapter 2 of Appendix H of the Draft EIS for additional details on the EIS approach to evaluating power system reliability and potential replacement resources and costs.
4582	11	N/A	N/A	As noted previously, PNGC Power recommends that further analysis is needed before a final EIS is issued to sufficiently quantify the potential socio-economic costs of blackouts.	The EIS estimates the costs of replacement power resources and transmission infrastructure needed to avoid increasing the risk of an outage, rather than estimating the costs of increased outage occurrence. Section 3.7.3.1, Base Case Methodology, at pages 3-819-21, 3-822-23 in the Draft EIS. Quantifying both the costs of restoring system reliability and the costs of outage events under the alternatives would risk double-counting potential impacts. See Section 3.7.3.1, Methodology, and Chapter 2 of Appendix H in the Draft EIS for additional details on the EIS approach to evaluating power system reliability and potential replacement resources and costs.
4582	12	N/A	N/A	The system reliability section (Appendix J p. J-viii) describes Conditional Value at Risk (CVaR), which means the average load not served. Table ES-8 of Appendix J, is a summary of notable CVaR events. Without the underlying studies and data, it is difficult to completely ascertain the impacts on society based on possible blackouts. However, some of the notable CVaR events are breathtaking, and not in a good way. For example, we need to translate 725aMW at 23.8% in August under MO4 in to expected blackouts. 725aMW is about equal to of the load of Seattle. Does this mean that MO4 (prior to mitigation) could result in blackouts equal to of Seattle? If so, for how long is the next key question. What is needed to create a complete socio-economic impact of outages, is to translate and expand the CVaR results to the expected magnitudes and durations of loss of load. In-other-words, how big are the expected blackouts and how long? This analysis would produce the range of Expected Unserved Energy (EUSE) or Energy Not Served (ESN) that the different alternatives produce as an outcome. The magnitude and duration (hours or days) of potential blackouts (i.e. EUSE) is a central question that the Draft EIS does not sufficiently address. Using EUSE or ESN figures would enable the federal agencies to estimate socio-economic impacts of outages and changes in reliability.	The EIS reliability modeling used the Northwest Power and Conservation Councils 2011 loss-of-load probability metric and standard. Neither the Council nor the North American Electric Reliability Council has established metrics or standards for Expected Unserved Energy and Energy Not Served. The EIS estimates the costs of replacement power and transmission resources needed to avoid increasing the risk of an outage, rather than estimating the costs of increased outage occurrences. Quantifying both the costs of restoring system reliability and the costs of outage events under the alternatives would risk double counting potential impacts. See Section 3.7.3.1, Methodology, and Chapter 2 of Appendix H in the Draft EIS for additional details on the EIS approach to evaluating power system reliability and potential replacement resources and costs. However, the CvaR metric does give an indication of the reliability risk if replacement resources were not acquired. For the example cited by the comment, a CvaR of 725 aMW in the first half of August for Multiple Objective Alternative 4 means that in one year out of 20 (average of 308 of the 6160 simulations), the average power shortage would be 725 aMW for the first half of August. Most likely, it would be larger power shortages during the afternoon and early evening and less or potentially no shortages later at night for over two weeks. This is indeed a very large impact. The CvaR metric assesses the impact in the worst 5% of years. There are also smaller impacts in other years. The LOLP for the first half of August, at 23.8 %, means that in nearly one year out of four, there would be power shortages in the first half of August.
4582	13	N/A	N/A	Several organizations such as utilities and ISO/RTOs have developed excellent modeling methodologies or approaches to quantify the cost of EUSE or blackouts. This information is then used to develop reliability targets and standards such as reserve margins. A central component to these approaches, is the development of Value of Lost Load (VOLL) or Value of Service (VOS) or "unserved energy." In plain language, this means, "cost of blackouts."	The EIS reliability modeling used the Northwest Power and Conservation Councils 2011 loss-of-load probability metric and standard. Neither the Council nor the North American Electric Reliability Council has established metrics or standards for Expected Unserved Energy and Energy Not Served. The EIS estimates the costs of replacement power and transmission resources needed to avoid increasing the risk of an outage, rather than estimating the costs of increased outage occurrences. Quantifying both the costs of restoring system reliability and the costs of outage events under the alternatives would risk double counting potential impacts. See Section 3.7.3.1, Methodology, and Chapter 2 of Appendix H in the Draft EIS for additional details on the EIS approach to evaluating power system reliability and potential replacement resources and costs.
4582	14	N/A	N/A	The Northwest Power and Conservation Council (NWPCC) did a survey of worldwide use of VOLL and VOS in approximately 2016-2017, and we suggest that the federal agencies look to this work since the Draft EIS already relies on other NWPCC work.	The EIS reliability modeling used the Northwest Power and Conservation Councils 2011 loss-of-load probability metric and standard. Neither the Council nor the North American Electric Reliability Council has established metrics or standards for Expected Unserved Energy and Energy Not Served. The EIS estimates the costs of replacement power and transmission resources needed to avoid increasing the risk of an outage, rather than estimating the costs of increased outage occurrences. Quantifying both the costs of restoring system reliability and the costs of outage events under the alternatives would risk double counting potential impacts. See Section 3.7.3.1, Methodology, and Chapter 2 of Appendix H in the Draft EIS for additional details on the EIS approach to evaluating power system reliability and potential replacement resources and costs.
4582	15	N/A	N/A	PNGC Power suggests that the federal agencies analyze the potential socio-economic costs of EUSE, or blackouts associated with MO3 and MO4. The underlying work that produced the LOLP results in the Draft EIS is likely a source for EUSE. To complete this analysis, the federal agencies will need to start with the CVaR-based work, and create magnitudes (MW), durations (hours) and probabilities (%) to develop EUSE or ESN. Assuming a range of $5,000 to $30,000/MWH for VOLL (Value of Lost Load), the estimated social cost of blackouts could range from tens of millions of dollars to amounts in excess of billions of dollars per year depending on whether the proposed replacement resources are adequate to provide the same excellent reliability of the LSRDs and federal hydropower system as a whole.	Substantial costs would likely result should blackouts occur. The EIS methodology includes the full incremental replacement resource cost necessary to return the region to a level where the likelihood of blackouts is equal among all the alternatives, such that comparisons can be made among the alternatives on an equal basis. The EIS assumes for each multiple objective alternative (MO) that sufficient resources are acquired to reduce the risk of blackouts to the level of risk that existed prior to implementation of each MO. Once replacement resources have been acquired, the risk of a blackout for each MO is effectively the same as the No Action Alternative. If the EIS had then also added to each MO the additional cost of a blackout, then the MOs would have double-counted the impact of blackout risk (i.e. the MOs would have included the cost of avoiding blackouts and the costs of blackouts).
4582	16	N/A	N/A	In summary, MO3 and MO4 are extreme scenarios with profound reliability implications that need to be further assessed and understood more carefully. We think the reliability implications of MO3 and MO4 are unacceptable based on the information the federal agencies have already presented. We strongly suspect that the areas that we have identified above for further consideration, will reinforce our conclusion that MO3 and MO4 are potentially worse than the Draft EIS concludes	The statement that MO3 and Multiple Objective alternative 4 (MO4) would have profound regional power reliability effects is consistent with the power analysis findings of the EIS, if replacement resources were not built. See Sections 3.7.3.5 and 3.7.3.6 Effects on Power System Reliability in the Draft EIS. As discussed in Sections 3.7.3.5 and 3.7.3.6, Coal Retirement Considerations, the combination of reductions in hydropower generation and the retirement of most coal-fired generation in the region would magnify the impact on the region beyond that studied in the base-case analysis.
4582	17	N/A	N/A	We encourage more analysis ofthe replacement resource portfolios to assure high confidence that they can perform in a manner tocreate the same reliability result as the LSRDs and federal hydropower system as a whole.	As described in the draft EIS in Appendix H, Power and Transmission and Section 3.7.3.1, Base Case Methodology, the EIS employs a variety of industry standard models such as GENESYS, HYDSIM, AURORAxmp, GridView and powerflow modeling to assess the potential power and transmission effects of Multiple Objective Alternative 3 (which includes breaching of the four lower Snake River dams) and the replacement resource portfolios. And in particular, the Lower Snake River Full Replacement (Used in Rate Sensitivity Analysis) discussion in Section 3.7.3.5 of the EIS, on page 3-905 in the draft EIS, discusses what power resources would be needed to replace all attributes of the four lower Snake River Dams.
4582	18	N/A	N/A	Finally, as described in our comments above about transmission, the transmission reliability issues must be better understood and evaluated in order to fully capture the risks and costs of MO3 and MO4 from a transmission standpoint as well as resources standpoint.	As described in Appendix H, Power and Transmission and Section 3.7.3.1, Base Case Methodology, in the Draft EIS, the analysis employs a variety of industry standard models such as GridView and powerflow modeling to assess the potential transmission effects of MO3 and Multiple Objective alternative 4 (MO4) as well as HYDSIM and GENESYS for evaluating the power generation and replacement resource portfolios. This analysis provides the level of detail Bonneville needs to make informed decision making about power generation and transmission effects.
4582	19	N/A	N/A	In summary, MO3 and MO4 are extreme scenarios with profoundly negative reliability implications that need to be further assessed and understood more carefully. PNGC is concerned that the full social costs of MO3 and MO4 are not fully understood and likely are much higher. Additionally, the risks associated with the replacement portfolios are not completely understood and need further evaluation in a final EIS	The statement that MO3, which includes breaching the four lower Snake River dams, and Multiple Objective 4 (MO4) would decrease regional power reliability is consistent with the findings of the EIS, should replacement resources not be built. The EIS outlines the risks associated with constructing replacement resources, and acknowledges potential delays in environmental compliance, permitting and other delays that could cause power reliability concerns as described in Sections 3.7.3.5 and 3.7.3.6, Other Social Effects for MO3 and MO4, respectively in the draft EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
4582	20	N/A	N/A	As we continue to pursue collaborative solutions as a region, such as the Flexible Spill Agreement, which is now a key component of the PA, we must be sure not to prioritize the promise of durable outcomes over informed, scientific-based decision making. One of the biggest risks associated with adopting Flexible Spill as a key component of the PA, is that it is by its nature a biological experiment that assumes unprecedented and yet-to-be tested new levels of spill. Most concerning, is that the extended operation at 125% Total Dissolved Gas (TDG) is an unprecedented action at these federal projects. We have already seen a flexible spill operation in 2019, with spill up to 120% TDG that showed little benefit to fish with some evidence suggesting that survival was reduced.	The benefit of flexible spill to salmon and steelhead relies largely on reduction in PITPH which is projected to result in increased SARs. Therefore in-river survival does not tell the whole story. It will take years to understand the true effect because adult returns are needed to calculate Smolt-to-Adult return rates. One year of in-river data to assess the benefits of flex spill is not adequate. The Preferred Alternative includes working with regional sovereigns to develop a study that will assess the effectiveness of increased spill regime on adult returns as well as assessment and adaptive management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts on juvenile migrants.
4582	21	N/A	N/A	To ensure a science-based check on these limitless state water quality adjustments for TDG, we insist that spill operations adopted by the PA continue to be based on section 7 ESA requirements, stipulating that federal agencies must consult with the Fish and Wildlife Service and/or National Marine Fisheries Service (Services) on activities that may affect ESA-listed species. We echo the guidance included in U.S. EPAs March 5, 2020 action letter to Washington State regarding Ecologys permanent revision to its TDG standards.	The co-lead agencies are in consultation with National Marine Fisheries Service and the U.S. Fish and Wildlife Service under Section 7 of the Endangered Species Act for this CRSO EIS. The biological opinions that result from these consultations will be appended to the Final EIS.
4582	22	N/A	N/A	Throughout implementation of the current Flexible Spill operation, and as further adopted, we urge the co-lead agencies to keep a close eye on this new and untested operational paradigm, particularly spill to 125% TDG. Specifically, to continue to analyze the impacts of the proposed action on ESA-listed salmon species. This includes the development of a robust monitoring approach and platform for providing the public with transparent feedback on impacts to fish	The co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. In order to address the uncertainty of the effects of spill to 125%, the co-lead agencies have provided an adaptive management framework is described in Appendix R. The agencies will address any unintended consequences from operations through this framework.
4582	23	N/A	N/A	Additionally, we encourage the co-leads to continue to refine their adaptive management framework to ensure that their actions do not jeopardize the continued existence of any listed species (as directed by section 7 of the ESA).	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. That call, however, is ultimately the role of NMFS and the USFWS. The final BiOps that analyze compliance with the ESA from NMFS and USFWS will be appended to the Final EIS.
4582	24	N/A	N/A	Along these lines, we support the co-lead agencies further review of concerns identified by Joe Lucas and Western Montana G&T related to increased spill operations under the PA. Specifically: 1) Risks identified by the NMFS LCM modeling saying that if latent mortality effects are not reduced under this operation, smolt-to-adult return (SAR) rates for Snake River spring Chinook may be lower than the No Action Alternative due to reduced rates of transportation (ES, Page 33); 2) Disproportionately negative impacts on steelhead due to their behavioral efforts to avoid Gas Bubble Trauma associated with the increased spill. Under this exceptionally high level of spill, we understand that steelhead will travel in the upper portion of the water column exposing them to greater avian predation; 3) Lack of comparative information in the Draft EIS around the impacts of the PA on steelhead. It appears that the co-lead agencies relied solely on the assumptions of the CSS modeling for claims about steelhead survival, noting that there is no NMFS LCM model for Snake River Steelhead; 4) Given the flexible spill component of the PA, and the associated risks to fish outlined in the Draft EIS, the co-leads must identify specifics around the study that will be conducted to either confirm or refute modeled assumptions related to reduced SARs under this untested operation; and 5) The need for much greater detail around fishery monitoring and how information about incidence and severity of Gas Bubble Trauma may be used to modify or reduce any unintended consequences associated with high levels of spill. Once again, we appreciate the input and expertise provided by Joe Lukas and Western Montana G&T, and urge the co-lead agencies to strongly consider these comments.	The CSS and NMFS Life Cycle models predicted different levels of effects of the preferred alternative on SARs, primarily due to how latent mortality is treated. To address this uncertainty and minimize risk, the Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as robust monitoring, assessment, and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts on juvenile migrants. The adaptive management framework is described in Appendix R.
4582	25	N/A	N/A	In summary, we cautiously support the PA developed by the co-lead agencies. However, we continue to have strong concerns around spill to 125% TDG (even for the limited durations specified in the Flexible Spill Agreement/PA). Therefore we request that the co-lead agencies develop programs to effectively monitor and evaluate impacts on fish, and adaptively manage the CRS as necessary to mitigate against further jeopardizing listed salmon species.	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
4582	26	N/A	N/A	We understand the significant challenges associated with addressing predation issues. Not the least of which, arise from multi-federal agency compliance with and implementation of the various (and often conflicting) federal laws that govern the management of the species at issue. To address this concern,we call on the co-lead agencies to take a leadership role in aligning with their federal agency partners, state fish and wildlife agencies, utilities and tribes to work collaboratively to develop a basin-wide strategy to combat the significant threat of predation to ESA-listed Columbia River Basin salmon and steelhead.	The co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. As for the suggestion that the three co-lead agencies (Corps, Reclamation, and Bonneville) take a leadership role in aligning regional entities, the species that are of concern due to their predation of anadromous fish in the Columbia River are managed by numerous entities, including Federal, state, and Tribal governments. These entities are guided by a complex array of policies, laws, and agreements. The three co-lead agencies (Corps, Reclamation, and Bonneville) have limited authority to manage avian predators.
4583	1	barbarajoblair@gmail.com	N/A	Beyond supporting the stated positions of the various Tribes included in Appendix P and otherwise previously stated, NCAG also supports the rights of any other native peoples who may not have been expressly included in the DEIS, such as the rights of individual Native landowners, including Palouse Tribal members, who have been removed and displaced from their ancestral lands due to these dams. Their rights to fish, access cultural and sacred areas, and practice traditions would also best be honored by breaching the 4 lower Snake River dams.	Tribal input was received during the entire development of the Columbia River System Operations Environmental Impact Statement (EIS) and tribal concerns, rights and interests, including treaty rights, were considered and incorporated throughout this EIS. Native Americans from non-Federally recognized tribes were provided the same opportunities to follow development of and comment on this EIS as the public-at-large.
4583	2	barbarajoblair@gmail.com	N/A	Sadly, by recommending their economic-driven Preferred Alternative, the co-agencies have once again failed to honor treaty rights, the U.S. governments fiduciary obligation to native people, and related social and environmental justice imperatives.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations treaties impose. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative. The co-lead agencies have strived to promote environmental justice, consistent with Executive Order 12898, in selection of the Preferred Alternative. The co-lead agencies analyzed the environmental effects, including human health, economic, and social effects, of the proposed action on tribal, minority and low-income communities across all alternatives. The Environmental Justice analysis in Sections 3.18.3 and 7.7.20 of the Draft EIS provides further detail on potential disproportionate effects to tribal, low-income and minority populations.
4583	3	barbarajoblair@gmail.com	N/A	NCAG also agrees with the significant deficiencies the Tribes have pointed out with the CRSO-DEIS process, such as: --The co-lead agencies failure to conduct an updated comprehensive survey like the 1999 Meyer Report, which was part of the last NEPA review, the Lower Snake River Juvenile Salmon Migration Feasibility Study, which final ROD issued in 2002; and --The co-leads failure to recognize the broader indigenous perspectives on what are trust assets, which the federal government has a fiduciary obligation to manage on behalf of the Tribes.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. As stated in that section, the treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations the co-lead agencies included as a purpose in the Purpose and Need Statement in Chapter 1: Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the Columbia River System Operation Environmental Impact Statement.
4596	1	powersupply@lcpud.org	Lewis County PUD	Public Utility District No. 1 of Lewis County, Washington (District) supports the findings of the draft EIS, most notably the exclusion of removal of the lower Snake River dams (LSRDs) as a preferred option moving forward.	Thank you for your comment.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
4596	2	powersupply@lcpud.org	Lewis County PUD	With consideration to the findings outlined in the Draft EIS, the District asks that the agencies continue to steer away from any preferred alternative that includes breaching the lower Snake River dams or reducing their effectiveness through increased levels of spill.	Thank you for your comment.
4596	3	powersupply@lcpud.org	Lewis County PUD	We encourage you to work with stakeholders on meaningful ways to help threatened and endangered salmonid populations without destroying this critical infrastructure. We also caution against any alternative that increases spill beyond 125% TDG without, at minimum, further research on how spill impacts out-migrating juveniles and returning adults. Additionally, contingencies should be put in place to ensure that if higher spill results in negative impacts on salmonids or other native species of fish, that spill is decreased to lower TDG levels	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component, of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal fish managers in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
4599	1	Clark Mather	Tacoma Power	Tacoma Power supports the Preferred Alternative and the significant progress it will provide toward ESA-listed species recovery and other impacted fish and wildlife. Tacoma Power believes that the Preferred Alternative represents a significant step forward for listed species recovery while limiting impacts to regional electric customers and our environment.	Thank you for your comment.
4599	2	Clark Mather	Tacoma Power	Tacoma Power is particularly sensitive to rate impacts that would add additional strain on limited-income customers, as approximately 25 percent of our customers qualify for our needs-based bill assistance programs.	The EIS evaluated potential effects to low-income populations in the Environmental Justice analysis. Section 3.18.3 of the EIS provides further detail on potential disproportionate effects to tribal, low-income and minority populations. The Preferred Alternative is expected to result in upward rate pressure around 0.33 percent for regional average residential retail rates. The effect would be larger for public power customers and range up to +1.1 percent in some counties (see Section 7.7.20 in the Draft EIS). Additionally, under the Preferred Alternative the Bonneville wholesale power rate pressure is estimated to be 2.7 percent relative to the No Action Alternative. A portion of that rate pressure has already been incorporated into the BP-20 wholesale power rates; and, the remaining rate pressure likely falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control.
4599	3	Clark Mather	Tacoma Power	Any outcome that reduces baseload carbon-free generation, like hydropower, jeopardizes future opportunities to achieve the requirements of Washington states Clean Energy Transformation Act, as well as reduction of greenhouse gas (GHG) emissions from other sectors of the economy.	The Preferred Alternative identified in the Draft EIS meets the Purpose and Need Statement and also seeks to meet the EIS objectives. While the Preferred Alternative meets the objectives for ESA-listed juvenile and adult anadromous salmonids, resident fish, lamprey, hydropower generation, water management and water supply; it does not meet the objective for greenhouse gas. The Preferred Alternative would increase greenhouse gases would by 1.5% or 0.54 million metric tons above the levels in the No Action Alternative.
4610	1	N/A	N/A	The Draft EIS fails to honor our treaty promises to native tribes. In 1855 the Natives Peoples of the NW signed a treaty with the U.S. government that ceded most of their lands (in Washington, Oregon and Idaho) in return for the right to have and to fish for salmon and steelhead in the usual and accustomed places. The United States has failed in its obligation to the Natives Peoples. The removal of the lower Snake River dams would go a long way in helping to restore the salmon to levels necessary to meet treaty obligations.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations treaties impose. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
4619	1	Jack Janda	N/A	Removing the dams will most likely increase our use of carbon-based generation and does not support the Washington State energy goals.	Section 3.8 and Chapter 7 of the EIS evaluates the extent to which the CRSO EIS alternatives influence the ability of the region to meet Washington State energy goals for carbon emissions reductions. Section 3.8 finds that Multiple Objective Alternative 3, which includes breaching the four lower Snake River dams would make these goals more difficult to meet. The Preferred Alternative estimates that GHG emissions would increase by 1.5% or 0.54 million metric tons compared to the No Action Alternative.
4619	2	Jack Janda	N/A	Removing the dams makes resource adequacy a challenge for the future and sets us up for our failure to meet our energy needs.	The measure to breach the four lower Snake River dams that was evaluated in MO3, was not included in the Preferred Alternative identified in the Draft EIS. The effects of the Preferred Alternative (PA) on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the PA. However, because of the shape of the remaining hydropower generation in the PA, the loss of load probability was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary. The EIS analyzed two resource portfolios to replace the hydropower generation of the four lower Snake River dams, both of which maintain regional power system reliability. See Section 3.7.3.5, at pages 3-904-910 in the Draft EIS. Under these replacement portfolios, regional power rate pressure increases. In the Draft EIS, see Section 3.7.3.5, at pages 3-918-924; and Table 3-166. Without replacement resources, however, the statement about the effects of breaching the four lower Snake River dams on regional resource adequacy is consistent with the findings of the EIS. In the Draft EIS, see Section 3.7.3.5, Effects on Power System Reliability, at page 3-903; and also Appendix H, Table 2-1.
4619	3	Jack Janda	N/A	Losing our dams has a negative effect on other river users, such as navigation, recreation, agriculture and will increase truck traffic along the Columbia River corridor.	The potential environmental, economic and social impacts from breaching of the lower Snake River dams are evaluated and described throughout the EIS organized by resource area. Human health and well-being are described in several socioeconomic-related resource areas including Power and Transmission (Section 3.7), Navigation and Transportation (Section 3.10) , Water Supply (Section 3.12), and Recreation (Section 3.11). Environmental and human health impacts associated with increased emissions to shipping goods by rail and/or truck are evaluated and described in the Air Quality Section (3.8), and increase health and safety concerns due to increased truck traffic on roadways and potential for increased accidents are described in the Navigation and Transportation Section for other social effects (Section 3.10.3.5).
4624	1	Joel Kawahara	N/A	Finally, with respect to the multiple objective alternatives, they do not really represent public sentiment. There have been very strong comments, mine included, on salmon recovery that are not fully addressed by any of the multiple objective alternatives. I suggest an analysis of a full recovery alternative.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their habitats. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
4624	2	Joel Kawahara	N/A	I have a comment about the preferred alternative, which says that economic and social disruption is minimized. I dispute that. That analysis does not take into account lost fisheries revenue from the building of the Columbia River System.	The co-lead agencies recognize that the maintenance and operation of dams in the CRS create effects to salmon and steelhead populations in the Columbia River Basin. However, the co-lead agencies also recognize that there are many stressors to these fish populations from outside the CRS hydro-system, including poor ocean conditions, harvest, and access to habitat. Current ocean conditions have limited adult returns up and down the west coast regardless of migration impediments. All four lower Snake River dams have high adult passage rates with conversion rates and juvenile survival rates in the mid to high 90%. In the recent screening conference held in Walla Walla this past year, Washington, Oregon and Idaho reported that between 70 and 80% of tributary habitats in their states had access issues either from perched culverts, unscreened irrigation returns, or blockages. A study conducted on one stream in the Salmon Basin reported that nearly all fish emigrating downstream were diverted in irrigation withdrawals. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. Again, there is uncertainty around recreational and commercial fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. However, the EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. The social welfare effects under MO3 on commercial fisheries are described as major and beneficial in the long-term in this reach, with increases in regional economic effects if commercial fish catch rates increase.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
4626	1	Elaine Kuen	N/A	We need to have extended hearings on this. This should not be decided in the middle of the Coronavirus epidemic. This should be postponed.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
4627	1	Terri Wright	N/A	First, I would like to stress that the comment period during this Coronavirus pandemic needs to be extended or rescheduled. Wading through the more than 5,000 pages of the draft Environmental Impact Statement in order to offer thoughtful comments is challenging in the best of times. These are not the best of times	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website reminded the public on April 9, that they should plan to submit comments by the close of the comment period.
4627	2	Terri Wright	N/A	Orca conservancy firmly believes the restoration of the Snake River is vital for preserving our salmon and our southern residents. We must continue the discussions that have been started between stakeholders to address and ensure the wholeness of each affected community, not only on what this will look like without the Snake River dams but how to get to that point	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by USFWS.
4627	3	Terri Wright	N/A	As the National marine Fishery Service acknowledged, new information confirms that southern residents spend substantial time in coastal areas of Washington, Oregon and California and utilize salmon returns to these areas. These coastal waters are recognized as an essential forging area for this critically endangered population in the winter and spring.	The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects, including information from NMFS regarding SRKW foraging behaviors. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613.
4628	1	Nina Sarmiento	N/A	MO-3 has been poisoned by including more spill, structural measures, and mitigation on other lower Columbia dams. Overestimated breach costs and unnecessary mitigation costs further poison the (inaudible). Thus, the actual cost of breaching has been inflated upwards of $600 million, despite analysis already done that it can be accomplished in half a million.	The Purpose and Need Statement of this EIS requires that the co-lead agencies develop alternatives to operate the CRS to meet congressionally authorized purposes. A single purpose alternative, such as dam breaching would not meet the purpose and need, nor would it provide a strategy and NEPA coverage for future operations and configurations of the CRS. As for the cost estimate, the co-lead agencies place priority on human health and safety. The plan proposed for breaching was developed to provide maximum safety for humans, including contractors doing the work, and those living in the vicinity of the breach and affected downstream areas. Cost estimates were developed to implement the plan using 2019 price levels.
4628	3	Nina Sarmiento	N/A	Closer look at the Appendix Q, cost analysis table or (inaudible) -3, shows that the breach estimate for the new EIS includes $212 million in annual capital costs from other dams. The four lower Snake Dams have no capital cost (inaudible).	The commenter is correct that under MO3, which includes breaching the four lower Snake River dams, Section 3.19 and Appendix Q correctly remove capital costs. Under MO3, it is assumed that future capital costs for end-of-life equipment replacements for the four lower Snake River Dams would not proceed as the dams are breached. For the remaining CRS projects, planned capital replacements are largely not affected by breaching the four lower Snake River dams.
4628	4	Nina Sarmiento	N/A	Similarly, the operation and maintenance cost for all other Columbia River System dams included in annual cost (indiscernible) breaching, when in reality only operation and maintenance costs for recreation will remain post-breaching. MO-3 has been falsely presented as extremely expensive; even so, evidence in MO-3 points to breaching as the only alternative that saves money, ratepayer money, and has the highest probability of recovering salmon and orca.	The Cost Analysis Appendix Q describes the costs by project for capital and operations and maintenance costs. Under MO3, the co-lead agencies would save approximately $107 million annually in these costs (Tables 4-1 and 5-1). Under MO3, there would no longer be co-lead agency costs incurred for recreation because it is anticipated that the co-lead agencies would no longer operate project lands for recreation after the projects are deauthorized. Recreational sites could be modified in the future as project land is transferred through real estate actions. Costs under MO3 include costs to breach and drawdown the four lower Snake River dams (see Annex A in Appendix Q) as well as additional mitigation measures to reduced adverse effects under MO3 (See Annex B of Appendix Q). From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal hydropower presentation at the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class is forecast to have a 50-year levelized cost of generation of $11.41/MWh based on the direct funded capital and expense programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Similarly, the Northwest Power Act does not obligate the co-lead agencies to recover ESA-listed species or to ensure restoration of other fish and wildlife. Instead, the co-lead agencies fish and wildlife mitigation responsibilities under Northwest Power Act are more limited primarily, managing and operating FCRPS projects, which includes the CRS, to protect, mitigate, and enhance (as opposed to recover) fish and wildlife affected by such projects in a manner that provides equitable treatment with the projects other authorized purposes and consistent with the purposes of the Act and applicable laws. In addition, Bonneville has a specific responsibility to fund protection, mitigation, and enhancement of fish and wildlife to the extent affected by development and operation of FCRPS projects consistent with the Northwest Power and Conservation Council (Council) fish and wildlife program, the Councils power plan, and the purposes of the Act, which includes assurance of an adequate, efficient, economical, and reliable power supply. The EIS analysis in Section 3.6 (Wildlife section) found only a potential for negligible to minor beneficial effect to the Southern Resident killer whale (SRKW) would result from implementing MO3 (which includes breaching the four lower Snake River dams). Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3, with long-term increases in wild prey. The co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5 and the fact that these additional hatchery fish should mitigate short-term construction effects to Snake River populations.
4628	5	Nina Sarmiento	N/A	The next thing I want to point out that that person stated is that the connection between orca, salmon, orca and the Snake River is very clear. And the fact that it's not even in the EIS is a fatal flaw.	The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The discussion of the issue identified in this comment is provided throughout the CRSO EIS, including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early

					spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613.
4628	6	Nina Sarmiento	N/A	I'm going to specifically cite Appendix Q, cost analysis Annex B, multiple objective specific mitigation cost, resource is anadromous fish. And so it's included in this breach alternative 78 million to release hatchery fish to help address the loss of fish in the river during breaching. And so clearly the mitigation action was misguided here because breaching has to occur when there are no fish in the river.	The breaching would be timed as well as can be controlled to take place outside of the migration period. The method proposed for breaching the four lower Snake River dams is based on extensive analysis completed for the 2002 Feasibility Study, which also considered dam breaching. The methodology developed is intended to minimize effects to ESA-listed fish runs, other aquatic organisms and the built environment, while providing maximum protection to human health and safety. The CRSO EIS uses the same assumptions. The co-lead agencies will continue to adhere to Federal standards for dam and levee safety and human life safety considerations. In the event that breaching of the four lower Snake River dams is implemented, additional analysis will be conducted to refine methods and costs. NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in Chapter 5 is not intended to indicate that the co-lead agencies, or the Federal government as a whole, have the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Record of Decision (ROD). Their inclusion in Chapter 5 serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide mitigation for the effects to private infrastructure such as irrigation pumps, wells, or private docks. The co-lead agencies do not have the authority to provide direct payments to farmers related to increased operation costs.
4628	7	Nina Sarmiento	N/A	Appendix Q, Annex B, multiple objective specific mitigation costs, navigation, transportation. And so it says that the impact of breaching MO-3 would result in high water velocities which would result in damage to the piers and the bridges. So we would need to protect them from erosion, and this would cost $203 million. And so this is an inconsistency that I thought that was wrong, because the armor is already on the piers and the bridges, because those piers and bridges were built before the lower Snake River dams were built	The co-lead agencies did use the information in the 2002 EIS to identify 25 existing bridges in the lower Snake River, their infrastructure assessment, and the Snake River embankments able to withstand scour at 500 year flow events. The 2002 EIS evaluation identified the piers and abutments of these 25 bridges would need additional armoring as well as 80 miles of embankment fill. Review of these findings concluded this would still be true for the CRSO EIS Multiple Objective alternative 3. The costs developed are based on these findings.
4628	8	Nina Sarmiento	N/A	I'll continue on to my next critique, which is in Appendix Q, Annex B, specific mitigation costs under navigation and transportation where it says breaching of the lower Snake River dams would cause sediment deposit in the navigation channel at the confluence of the Columbia upper part of McNary Reservoir. And so this is completely false. They allocate $108 million for mitigating this sediment that they say would be deposited so they would have to dredge. However, this mitigation cost was not in the 2002 EIS breach alternative mitigation cost. And so why? So it's because it's not a real mitigation cost.	The EIS estimates the costs to operate the CRS dams, as well as the costs to the navigation industry that would be occur if the lower Snake River dams are breached under MO3. The EIS evaluated all of the tradeoffs associated with the management of the system, which has multiple purposes. It was not an analysis that aimed to compare the benefits of navigation against the costs to salmon. Direct and indirect effects of MO3, as compared to the No Action Alternative, include downriver sedimentation as described in cumulative effects Table 6-11 (Section 6.3.1.2.4). Near-term sedimentation effects following the MO3 Breach Snake Embankments measure are predicted to last up to ten years (depending on the hydrologic regime) as legacy sediment deposits within the former reservoirs are incrementally eroded and re-deposited throughout the lower Snake Reach. Near-term sedimentation effects are expected to be particularly large in the upstream end of Lake Wallula on the Columbia River. The impacts of sediment deposition at left bank recreation and boat-launch sites below the Snake confluence would likely be permanent. Long-term sedimentation effects would include continued deposition in quiescent areas prone to shoaling as a result of annual sediment delivery that had previously been trapped by the lower Snake River dams, but not directly interfere with Columbia River navigation. Mitigation actions for these potential impacts to navigation are detailed in Section 5.4.3.5 and propose dredging to maintain this reach of the Federal navigation channel. Likewise, public and private port facilities both near the confluence of the lower Snake River and on the left bank of Lake Wallula would need to conduct sequential dredging in order to avoid interruptions in service and maintain access to the navigation channel. Dredging mitigation for maintaining the Federal navigation channel would be a Corps' expense, while dredging to maintain port facilities and access to the Federal navigation channel would not be a Corps' expense. Dredging operations are expected to remain similar to No Action Alternative in the remaining reach of the Columbia River navigation channel.
4628	9	Nina Sarmiento	N/A	And federal agencies in this DEIS gave a price tag of 400 million for irrigation mitigation. And they got to that price by devaluing the amount of irrigated land and then recording that loss. And that's just absurd. That solution is not helpful for anyone.	In Region C (lower Snake River), and potentially Region D (mainstem Columbia River) around the confluence of the lower Snake River, MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams will reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected. Additionally, transportation of farming goods would expect to move off river and on to rail or trucks, as there would be a complete loss of commercial navigation on the lower Snake River and could not be feasibly mitigated. All ports along the Snake River would lose access to the navigation channel. Some ports at the confluence or the Snake and Columbia River could dredge new channels to the Federal channel in the confluence (McNary reservoir) to maintain access. Private or public entities or businesses could take actions and/or build infrastructure to extend pumps or water supply access for water. Ports and farmers can likewise change their transportation modes or connect to the navigation system at a different point on the river. The federal co-lead agencies would not mitigate for these impacts to water users or ports. See Chapter 3 analyzes the social and economic effects of implementing a dam breaching alternative (MO3) and Chapter 5 for mitigation discussion.
4630	1	LeeAnne Beris	N/A	The federal agencies' approach in this DEIS maintains the status quo that resolves none of these challenges and meets no one's needs. The state's community is calling on Northwest elected officials, federal agencies, and policymakers to work with each other as well as Northwest tribes, farmers, fishermen, community leaders, and all other river stakeholders, to develop a salmon recovery -- -- to develop a salmon recovery plan that actually restores salmon and ensures a prosperous region for everyone.	The co-lead agencies concur that regional salmon recovery planning is best accomplished collaboratively and is more suitable for completion outside of an EIS process. Based on our analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. In compliance with ESA, the co-lead agencies submitted biological assessments to NMFS and USFWS (Appendix V). In this Final EIS, the Biological Opinions from NMFS and USFWS can be found in Appendix V, completing this projects ESA consultation.
4631	1	Chad Jensen	N/A	I'm Chad Jensen, and I'm honored to serve as the CEO of Inland Power and Light based here in Spokane, Washington. The draft EIS is an impressive document, and I tip my hat to all the effort put in by the three agencies. I want to start off by saying dams are meaningful to our area and the entire Northwest. Dams provide us with carbon-free power that meets our state mandates and provides a reliable backup for renewables. If the dams are removed, the impact on rates and our Northwest economy would be significant.	The comment that Multiple Objective 3, which includes breaching the four lower Snake River dams, would increase power costs and adversely affect the integration of renewables in the region are consistent with the findings in the EIS. See Section 3.7.3.5, at pages 3-918-924 in the Draft EIS; see also Table 3-166 in the Draft EIS.
4631	2	Chad Jensen	N/A	Dam removal is projected to raise BPA rate by as much as 50 percent. To us, that translates to up to 25 percent for our members. This power also cannot be replaced without impacting rates in our carbon-free footprint.	The statement that wholesale power rates could increase up to 50 percent is consistent with the findings for Multiple Objective alternative 3 of the EIS. See Section 3.7.3.5, at pages 3-918-924 and Table 3-166 in the Draft EIS. The statement that replacing lost hydropower could increase carbon emissions is consistent with the findings of the EIS. See Section 3.8.3.5, pages 3-1009-1010 in the Draft EIS.
4631	3	Chad Jensen	N/A	I support the EIS suggested action and note that even the draft EIS shows that losing the lower Snake River dams would double the risk of regional blackouts. They are important to our economy. They're important to our future.	The EIS analyzed two resource portfolios to replace the hydropower generation of the four lower Snake River dams, both of which maintain regional power system reliability. See Section 3.7.3.5, at pages 3-904-910 in the Draft EIS. Under these replacement portfolios, regional power rate pressure increases. Without replacement resources, however, the statement about the effects of breaching the four lower Snake River dams on regional power reliability is consistent with the findings of the EIS. In the Draft EIS, see Section 3.7.3.5, Effects on Power System Reliability, at 3-903; and Appendix H, Table 2-1.
4632	1	John Francisco; John Francisco	Northwest Requirements Utilities (NRU)	The spill regime identified in the preferred alternative relies on spill to generate total dissolved gasses well above recommended levels. Spill at this level has not yet proven to be beneficial to fish stocks. NRU strongly encourages the lead agencies to expeditiously design and implement a robust fish monitoring program to ensure the proposed spill levels deliver the increases in population shown in the model. Implementation and monitoring must be followed by a willingness to invoke the adaptive management protocols to quickly adjust spill levels and increased fish survival is not shown.	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects of free swimming fish; and therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2, Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, Tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams, such as the Technical Management Team.
4633	1	Gary Wiens	N/A	The draft EIS points out that the cost of replacing these dams would result in approximately$1 billion annual increase to electricity costs. This would result in a 25 percent increase in our folks' monthly electric power bills. That's just simply unacceptable, unaffordable. Montanans, we're generally a low-income state. And I know many of the people that are served by our electric co-ops, they are low-income people. They just simply can't afford a 25 percent increase.	The comment that power costs in the region would increase under Multiple Objective 3, which includes breaching the four lower Snake River dams, is consistent with EIS findings. See Section 3.7.3.5, at pages 3-918-924 and Table 3-166 in the Draft EIS. Chapter 5 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as for urban and rural utility customers. The comment that increases in utility costs can adversely affect vulnerable groups is also consistent with discussions in the EIS. The Environmental Justice analysis in Section 3.18.3 and Chapter 7 provides further detail on potential disproportionate effects including to Tribal, low-income and minority populations. For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs over which it has significant control.
4634	1	Joshua Crowe	N/A	As a recreation professional, I implore you to look closely at the economic benefits that a free-flowing 200-mile section of river would bring to the region. On a purely economic basis, a free-flowing Snake River would greatly benefit the region. But the benefits of a free-flowing lower Snake River — would extend far beyond purely the economic.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region.
4638	1	Julia Good Stefani	N/A	My name is Julia Good Stefani. I'm an attorney with the Natural Resources Defense Council. My first request on this call is for an extension of the public comment period. Given the COVID-19 situation, I don't believe the public has a meaningful opportunity here with just 45 days to comment on a nearly 8,000-page document. And we'd ask the agencies, as we've done in writing, to consider an extension so that more people can join.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website reminded the public on April 9, that they should plan to submit comments by the close of the comment period.
4639	1	Laura Ackerman	N/A	I would ask that we expand the comment period to 120 days, because every American has had their lives upturned by the coronavirus. People are distracted and worried, and we need more time.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website reminded the public on April 9, that they should plan to submit comments by the close of the comment period.
4640	1	grooovyjake@gmail.com	N/A	Climate change is a real threat to our region, but we must understand why that is. Warming temperatures mean warmer rivers and an increasingly acidified ocean. The series of dams on the lower Snake and lower Columbia rivers nullify the cooling properties of a free-flowing river, creating a homogenous body of slow, hot water.	The decline of salmon populations is complex and recovery of those species will take collaboration between various agencies including NOAA and the Tribes. The co-lead agencies acknowledges that the ocean environment is a contributor to the decline in salmon populations that is beyond the scope of the CRSO EIS. While none of the alternatives would affect ocean conditions, we recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of this environment in the return of adult salmon and steelhead (Peterson et al. 2019). As such, two of the models used in these analyses, NMFS Lifecycle and CSS models, use metrics of ocean productivity to predict adult returns. The carbon-free attributes of the Federal hydropower system are described in the Air Quality Section of the Draft EIS (Section 3.8). The analysis includes the effects to GHG emissions resulting from changes in hydropower generation for each alternative, including breaching the Lower Snake River dams in MO3. Breaching the four lower Snake River dams would result in long-term benefits including improvements to fall water temperatures and the restoration of the river to more normative riverine processes; this is stated in Chapter 3, pages 3-271 through 3-272 and Appendix D, Section 6.2.3. Under a dam breach scenario, spring water temperatures will warm more quickly than No Action conditions. Similarly in the fall, under a dam breach scenario, fall water temperatures will cool more quickly than No Action conditions. These results make logical sense and are supported by results from CRSO numerical water quality modeling. What has surprised some stakeholders are the predicted summer water temperature effects under dam breaching. Many believe that removing the dams will result in colder water temperatures as compared to the No Action Alternative. While some cooler water temperatures may be observed in the summer under dam breaching, especially during cooler summer weather conditions and at night, water temperatures will remain warm and exceed the state water quality standard at times. This is because without the dams, the lower Snake River will be shallower and more susceptible to solar radiation and warming. Increases in water particle travel time are expected, but the lower Snake River has always been a warm system (USGS 1960, 1961, 1964; Corps 2002a) and breaching the dams will not change this fact. Regionally high air and water temperatures result in water quality standard exceedances and are beyond the ability of the CRS to cool; future climate change predictions will result in even more difficult challenges.
4641	1	Jim Bryne	N/A	In this DEIS, not all costs are included. For example, the cost to dredge Snake River annually is $12.8 million a year, and that's not referenced. In the breaching option, increases in appliance efficiencies, wind, and solar power are downplayed.	Costs to dredge the lower Snake River are included in the cost analysis described in Section 3.19 and Appendix Q; they are included in the operations and maintenance costs, described in Appendix Q, Section 5.1.2.3. According to Corps district navigation experts, dredging costs for the four lower Snake River projects are estimated to cost $3 million annually. Dredging costs were developed based upon historic dredging quantities and costs. Although these costs may generally be referred to as simply dredging costs or navigation dredging costs, dredging outside of the federal navigation channel could still occur in the future if needed and are captured within the historic quantities. Dredging costs were included for all alternatives, and it is recognized that dredging would no longer be needed on the lower Snake near Lewiston, ID under MO3. All cost effective conservation (energy efficiency) identified by the Councils 7th Power Plan is included in the load forecast. Under Washington and Oregon law, all cost effective conservation must be acquired regardless of the status of the FCRPS. Therefore, conservation was not considered a potential resource replacement, as this would have risked double counting. The source of resource information used in the EIS is from the Northwest Power and Conservation Council's 7th Power Plan and Mid-term update. The EIS identified solar was a component of a potential portfolio of replacement resources for MO3. See Section 3.7.3.5. Wind was also considered, but was not as cost-effective for replacing the lost hydropower generation in this alternative.
4641	2	Jim Bryne	N/A	We would also like to see an extension to the comment period.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
4642	1	Scott Simms	Public Power Council PPC; Public Power Council (PPC)	since the time the DEIS was initiated, the regional power supply outlook has been evolving rapidly, due to accelerated retirements of thousands of megawatts of coal capacity and with the addition of more intermittent renewals on the grid. The Northwest Power Pool and regional utilities have identified a growing resource adequacy need in coming years to maintain reliability and prevent blackouts.	Consistent with this comment, the EIS finds that increasing retirement of coal power plants would adversely affect regional power reliability (see Section 3.7.3.2, Effects on Power System Reliability, and Section 2.3 of Appendix H, Sensitivity of LOLP to Assumptions about Coal Capacity in the draft EIS).
4642	2	Scott Simms	Public Power Council PPC; Public Power Council (PPC)	At the same time, hydro played an ever increasing critical role in integrating intermittent renewable resources. DEIS, particularly MO-3 and MO-4, show the replacement cost of the lower Snake River dam capacity with zero emissions carbon resources would cost nearly $1 billion every year.	The statements that hydropower is important for the integration of new renewable power and that power costs in the region would increase under Multiple Objective (MO) Alternative 3 (which includes breaching the four lower Snake River dams) and MO4 are consistent with the findings of the EIS. See draft EIS, Section 3.7.3.1, Integration Services at page 3-832; Section 3.7.3.5 at page 3-904; Section 3.7.5.6 starting on page 3-940; and Appendix J, Section 4.3.Integration of Other Renewable Resources and Hydrosystem Flexibility Analysis at pages H-4-20 to 4-H-4-24.
4642	3	Scott Simms	Public Power Council PPC; Public Power Council (PPC)	So given this reality of thermal retirements, the cost of full replacement of lost hydro capability from alternative operations, including the ability to integrate other renewables into the grid, we believe such issues should be updated with more recent developments in the co-lead agency CRSO documentation and that the matter should be taking center stage in the final EIS.	As explained in Section 3.7.3.5 of the draft EIS, Potential Replacement Resources and Associated Costs, breaching the four lower Snake River dams would have a direct and substantial impact on the supply of Federal power to meet regional load requirements. These impacts would impact both actual energy to meet regional load requirements and generating capacity (peaking capacity) to meet variability in loads. The four lower Snake River dams are among the most valuable projects in FCRPS. These dams provide over 1,000 MW of carbon-free energy and up to 2,000 MW of sustained peaking capacity at certain times of the year. The dams also have unparalleled ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to approximately 2,300 MW of capability in certain months of the year (see Table 3-160 in the draft EIS). While the increase in solar and wind generation is consistent with the EIS discussion in 3.7.2.1 Power Generation in the draft EIS, the EIS still finds that the regional power system requires replacement power resources to maintain reliability under Multiple Objective Alternative 3. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review (see Footnote 1 below), the Headwater/Lower Snake Asset Class (see Footnote 2 below) is forecast to have a 50-year levelized cost of generation (see Footnote 3 below) of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. Footnotes: 1. The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2. In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3. Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
4643	6	kairos42@earthlink.net	N/A	And when you use correct assumptions, and I'm just talking about assumptions, some basic fatal flaws in the assumption and the planning process back in 2000, which has been repeated now in this DEIS when they said they basically escalated cost from 2019 -- or 1999. And what you get is, is if you correct these costs, it turns out breaching by itself will save $100 million a year in terms of capital, O&M, and construction cost for additional hardware on lower Columbia dams and Snake River dams. Even if you keep all that stuff in there, it still saves $57 million a year. So the preferred alternative is going to cost $51 million a year, but breaching will save anywhere from 50 to 100 million dollars a year.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. A table added to Section 7.4 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a number of the resource areas as well as the implementation costs of the alternatives. The commenter is correct when describing the costs to operate and maintain the lower Snake River dams. Compared to the No Action Alternative, MO3 would reduced costs between $53 and $158 million annually. Compared to the No Action Alternative, the Preferred Alternative would range from a decrease in costs of $40 million to an increase in costs of $7 million annually. However, these figures do not consider the benefits provided by the lower Snake River dams, including hydropower, navigation, water supply, and recreation.
4644	1	Bob Sallinger	N/A	Tonight I am testifying on behalf of Portland Audubon and our 17,000 members. I would simply begin by thanking you for the opportunity to testify before you, but I don't feel thankful for this opportunity tonight. The decision to move forward with these phone hearings in the midst of the COVID-19 crisis just two days after Oregon issued its stay-at-home orders is a disgrace. My organization, like so many others, is working nonstop to take care of our staff, support our volunteers and communities, maintain critical operations and comply with best practices in light of an unprecedented crisis. Even prior to the COVID-19 outbreak, you chose the process with a public comment period of only 45 days, a length of time that you were fully aware was inadequate to allow for meaningful public review of a document that's over 8,000 pages. This is a highly complex plan. Your decision to proceed with	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				hearings and refusal to extend deadlines cuts the public out of this process and benefits big corporate stakeholders that have the capacity to respond under these circumstances. Again, it's simply a disgrace and it shows a stunning indifference to public participation process.	
4644	4	Bob Sallinger	N/A	And you have scapegoated native predator species such as cormorants and sea lions, despite overwhelming public opposition as a way to divert attention from your chronic failures. The slaughter of cormorants on East Sand Island will range among the great wildlife travesties of the last century.	The co-leads appreciate your concern for native predator species. However, the co-lead agencies are required to ensure operation of the CRS complies with the law. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
4644	5	Bob Sallinger	N/A	the strategy appears to be to bring forward plans that you know are inadequate, get sued, lose in court, and then wash, rinse, and repeat. And sadly, this has worked for you. You have delayed recoveries for nearly a quarter of a century. Unfortunately, what it has not worked for is the salmon and the communities that depend on them, and the salmon move closer and closer to extinction. And your current plan — perpetuates this trend. We have lost faith in you and your process. We look to Northwest policymakers to step in and craft real solutions that you have so carefully avoided. We look to the federal courts to truly hold individuals and agencies accountable for chronic and systemic flouting of the law.	Based on our analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. In compliance with ESA, the co-lead agencies submitted biological assessments to NMFS and USFWS (Appendix V). In this Final EIS, the Biological Opinions from NMFS and USFWS can be found in Appendix V, completing this projects ESA consultation.
4645	3	Manly Norris	N/A	I would also request that they extend the comment period in light of the coronavirus.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
4648	1	Keith Kutchins	N/A	So the way this EIS develops alternative is to meet fish needs only after the primary manmade uses of the river, such as water supply and electricity production have been met. But instead, this EIS should develop the preferred alternative that first meets the needs of the fish, then meets the other multiple objectives of built capacity of manmade uses	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
4649	1	Kurt Miller	Northwest River Partners	There is overwhelming evidence shown in the EIS and very clearly documented, but also supported by many of the region's energy forecasters, including Energy Strategies, which is the group that wrote the Northwest Energy Coalition Study, which had earlier, based on 2016 assumptions, said that the lower Snake River dams could be easily and affordably breached. They have now come forward and said that they're actually forecasting an energy shortage for the Pacific Northwest. The fact is that so many coal-fired generating units have retired, it's actually put us in a much different situation than we were in 2016, when they developed their assumptions. Even though the actual forecast wasn't released from them until 2018, they used those older assumptions	The statements regarding potential resource adequacy concerns are consistent with the discussions in the EIS. See draft EIS, Section 3.7.3.5, Effects on Power System Reliability at page 3-903 and Appendix H, Table 2-1. Given upcoming coal retirements, the EIS findings indicate that the region would likely experience a significant regional deficit of power, which would require adding additional power resources to maintain power system reliability at the No Action Alternative levels. See Sections 3.7.3.3 through 3.7.3.6 in the draft EIS.
4664	1	Jacqueline@waptus.com	N/A	So I also want to add to my comment the fact that there's great frustration that this comment period was shortened and that agencies refuse to consider the implications of the coronavirus on public participation for the comment period. In short, the public participation cannot be at its fullest when we are all dealing in this context of a global pandemic.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
4665	1	Joel Brady-Power	N/A	We need to restore our salmon runs and protect the vibrant coastal communities who depend on them. The preferred alternative in the DEIS fails to do this. It does not meet the needs of Northwest communities and it has threatened the survival of salmon, orcas, and the livelihoods of fishermen and their communities. Salmon returns to the Snake and Columbia River are currently at all-time lows. Scientists tell us that the single best action we can take to help these endangered salmon is to restore the Snake River by removing its four dams.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. There has been a decline in returns of upper Columbia and Snake river Chinook and steelhead between 2016-2020, however salmon returns are not at an all time low to the Columbia. Following construction of Bonneville Dam in 1937, ladder counts of hatchery plus wild adults from all salmonids combined averaged approximately 600,000 between the 1930s-1990s. Adult returns trended upwards in the most recent 20 years, with average returns from 1-1.5 million. Fall Chinook are the most important ESU for coastal fishing and orcas because they tend to stay close to the coastal shelf; the upper Columbia summer/fall ESU remains unlisted, and the Snake River fall Chinook ESU has been trending towards recovery. Multiple factors could contribute to the increase in abundance and recent decline including increased hatchery production, habitat restoration, ocean conditions and climate, and changes in hydrosystem operations. The CRS technical teams designed Multiple Object alternatives to evaluate different levels of spill in MO1 ,2, and 4 based on extensive public comment and technical literature that showed evidence for the effectiveness of spill operations and surface passage structures that reduce forebay delay times and increase juvenile fish passage survival. Spill was a key strategy for improving dam passage since the 1990s with research carried out to determine appropriate volumes at a range of river flows, balance across the different spillbays, and design of surface level intakes. If dam survival and adult abundance had continued to sharply decline despite adoption of higher spill levels, this would be poor evidence for the success of the strategy. There are still many uncertainties related to the upper limits of spill when high TDG conditions may cause physiological harm to smolts and high spill has resulted in poor tailrace conditions for both adult passage and juvenile travel. In addition, there are other concerns: potential deleterious effects of hatchery production on recovery of wild populations, climate change and more. The Preferred Alternative includes an adaptive management plan (Appendix R). This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts on juvenile migrants.
4666	1	Tela Aadsen	N/A	Restoring and preserving salmon is critical to our region's well-being. The DEIS does not meet this need. The salmon returns to the Snake and Columbia River is at an all-time low. Scientists have repeatedly identified the removal of the four lower Snake River dams as the single best action we can take.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species as that is a broader goal with shared responsibility. Based on our analysis of the fish resources section of Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The EIS set forth eight objectives which, in tandem with the purpose and need statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the preferred alternative also meets the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. The alternative that includes a measure to breach the lower Snake River dams, by contrast, has significant regional economic impacts and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend dam breaching because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
4667	1	William Grimes	N/A	First, while I appreciate the opportunity to participate via this conference call, it's a poor substitute for an in-person hearing. It should not remain the only opportunity we have to present our comments, to hear from others interested in this proposal.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period. In response to COVID-19 concerns and public health requirements within the comment period, the agencies converted the six planned in-person regional public comment meetings to conference calls that provided an approach consistent with the format of the planned in-person comment meetings. To ensure adequate opportunity for the public to provide comments on the Draft EIS, the agencies hosted an online comment platform, providing mailing addresses for written comments, and hosted a series of public comment meetings by telephone. The co-lead agencies offered these public comment meetings by telephone to maintain our commitment to accepting verbal comments in accordance with current public health guidelines. These teleconference meetings were structured similarly to the previously scheduled in-person public comment meetings and provided speakers with the same amount of time to submit a verbal comment.
4667	2	William Grimes	N/A	the draft EIS appears to only superficially describe the impacts to communities and facilities if the dams are to be retained. Rising sediment levels and the difficulties in dredging will likely require building taller levies and constructing multiple road and rail bridges in response. These changes will have significant impact on the communities along the river, impact that must be more fully identified and addressed in the draft. As it is written, it appears that dam retention simply maintains a status quo, and that is both misleading and untrue.	Maintaining flood risk management operations of the Columbia River System has informed both the alternative development and evaluation process. However, the four lower Snake River dams are not authorized for flood risk mitigation and there is no elevated flood risk for any of the EIS alternatives. The EIS alternative evaluation also accounts for any dredging that may be necessary for flood conveyance in the Lewiston area. See Section 3.9 and Section 7.7.11 for more information on flood risk management.
4667	5	William Grimes	N/A	I ask that you extend the comment period both to allow opportunities for those unable to participate tonight and to permit public review and comment of a more honest dam retention alternative, one that adequately addresses community impact and the cost of rising river levels.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
4668	1	Peter Sallinger	N/A	I'm disappointed that federal agencies have decided to move forward with phone hearings and ignored requests to allow a reasonable timeline for public comment. It shows a real disrespect for public engagement.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
4668	2	Peter Sallinger	N/A	I urge you to select an alternative that does the following: number one, breach the four obsolete Snake River dams; two, improve flows over the Columbia River dams to benefit salmon; three, stop scapegoating native predator species such as cormorants and sea lions.	The CRSO EIS documents the assessment of benefits and impacts of changes to the operations of the 14 Federal projects of the Columbia River System. Using a multi-disciplinary approach and with the coordination and consideration of our cooperating agencies and Tribes, as well as public stakeholder input, and by using high quality information, the co-lead agencies developed the Preferred Alternative.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Increasing flows as a potential measure was evaluated in the EIS. In particular, the McNary flow measure in MO4 demonstrated significant adverse effects to upper Columbia basin fish and wildlife, as well as cultural resources. Certain native predators adversely affect survival of listed fish species and taking actions to keep a balance is a tool in our strategy. These decisions aren't made lightly and are coordinated with resource agencies such as NMFS and USFWS. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
4669	1	Lucy Depaolo	N/A	And I also believe deeply in inclusion of public comments and public process, and I would like to ask for an extension of this process.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
4672	1	Bob Rees	N/A	The federal government has had two decades and several federal lawsuits to get it right, but the salmon crisis remains an obstacle to robust borough commerce and propagates an adversarial environment between neighbors in our rural communities. The current DEIS does much of the same and, most importantly, continues the trajectory of the extinction of wild salmon forever from the Columbia River basin. This is something we simply cannot accept as a society. While the warm-water blob and poor ocean conditions do have a role in the downturn of Snake River salmon, in 2015, the lethal summer water temperatures in the main stem Columbia and Snake rivers killed over 90 percent of sockeye salmon return and compromised countless baby salmon en route to the Pacific Ocean. Countless broodstock sturgeon were also killed in the hot water in the pools above Bonneville Dam, compromising the future of this 200 million-year-old species.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
4677	1	Roberta Joyntner	N/A	My concern is that we are about to embark with the preferred alternative on one that will not work, because it doesn't address the two remaining factors. Granted, there are other global issues at play here. But without additional flow over the Columbia River dam, habitat restoration, and, most important, removal of the four Snake River dams, we're not addressing the key limiting factors in the system. The Snake River basin is huge. The pools above the dam preclude the smolts from getting to the ocean in time for their ocean window. And any plan that doesn't include addressing those dams won't work and will perpetuate the status quo, waste a lot of resources and a lot more time and end up in court more.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data scientific information was used for this analysis. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address the uncertainty due to the different model results, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, and Total Dissolved Gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative also carries forward existing habitat restoration programs and proposes additional actions in certain areas affected by CRS operations, maintenance and configuration. Increasing flows as a potential measure was evaluated in the EIS. In particular, the McNary flow measure in MO4 demonstrated significant adverse effects to upper Columbia basin fish and wildlife, as well as cultural resources.
4681	1	Barbara Hachmann-Sarmiento	N/A	From an economic standpoint, I think that the draft Environmental Impact Statement is not going to save taxpayer money. The lower Snake River dams are losing money every year. And choosing a breach would actually safe money. Breaching the lower Snake River dams is not only a good choice economically, but also biologically. The Southern Resident killer whales and the Snake River salmon and steelhead will not survive this new Environmental Impact Statement study process. As a first step, the federal agencies can and they need to begin breaching the four lower Snake River dams this year. The federal agencies can no longer afford to drag the process out with another Environmental Impact Statement that will take years while the salmon and the orca go extinct. In addition, the BPA's financial situation will worsen each year and that money will (inaudible) on the dams. Expensive bypass systems and more spill have been tried, and, yet, 2019 was another year of costly efforts to recover Snake River salmon with no results.	The Corps does not have authority to breach the four lower Snake River dams. Consistent with the twin aims of NEPA, the agencies provided notice to the public in the Draft EIS of the Corps' existing authorities and the stepwise process that would be required if the co-lead agencies selected Multiple Objective 3 (MO3) as the Preferred Alternative (PA). If this occurred, the PA would serve as a recommendation to Congress, which Congress would need to authorize. Congress would also need to authorize additional studies, including NEPA analysis, and funding for implementation. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Table 7-1 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives. Contrary to the comment, the EIS analysis did determine that the four lower Snake River dams are cost-effective. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric. There are also benefits and costs associated with operating the lower Snake River projects. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the CRS include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKW foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.5). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council.
4692	1	Leah Sarmiento	N/A	In order to save endangered Snake River salmon, Southern Resident orca, and ratepayer money, the federal agencies should address the Columbia River system in a two-tiered process. Tier one is an emergency response action for the immediate drawdown and breach of Lower Granite and Little Goose Dam, followed by the remaining two dams in subsequent years. Tier two is addressing system operations and further mitigation activities in the rest of the Columbia River basin using the new EIS, assuming that the four lower Snake River dams are breached. The two-tiered approach should be initiated for the following biological and economic reasons: endangered Snake River salmon and steelhead have not recovered since 2002 EIS was implemented and have gotten much worse over the last four years; wild stocks may not survive further studies foreseen in the CRSO process; the economic benefits of the dams to the region have declined and operational costs have risen. The Army Corps of Engineers already spent seven years and 33 million of rate and taxpayer money on the 2002 EIS with a breach alternative. The two-tiered approach can be accomplished following the existing guidelines. The Army Corps of Engineers has a fiduciary responsibility to cease operations and place a project into a non-operational status when projects are losing money economically or causing unresolved or biological harm, that the Corps doesn't need specific authorization to secure the project by breaching. The federal agencies have responsibility to comply with the Endangered Species Act and to take actions necessary to recover endangered salmon, steelhead, and Southern Resident orca. Breaching can be paid for by BPA as the least cost way to accomplish fish mitigation under the 1980 Northwest Power and Conservation Act and as a means of transferring savings from lower Snake River dams to other Columbia River dams.	Contrary to the commenter's suggestion, the Corps does not have the authority to immediately breach the four lower Snake River dams. If MO3 were selected, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the four lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes. Chapter 7, Preferred Alternative, describes the process used to select the Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. The costs to operate the system and implement the selected alternative are funded through multiple mechanisms including Federal appropriations to cover system costs, as well as revenue generated through the marketing and sale of hydropower. The Corps and Reclamation receive annual Congressional appropriations to fund system capital, and operations and maintenance activities. Bonneville funds the power-share of these costs to the Corps, Reclamation and USFWS. In addition, Bonneville is responsible for repaying the U.S. Treasury for a share of the appropriations if it is determined that the costs are appropriately allocated to power. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Similarly, the Northwest Power Act does not obligate the co-lead agencies to recover ESA-listed species or to ensure restoration of other fish and wildlife. Instead, the co-lead agencies fish and wildlife mitigation responsibilities under Northwest Power Act are more limited primarily, managing and operating FCRPS projects, which includes the CRS, to protect, mitigate, and enhance (as opposed to recover) fish and wildlife affected by such projects in a manner that provides equitable treatment with the projects other authorized purposes and consistent with the purposes of the Act and applicable laws. In addition, Bonneville has a specific responsibility to fund protection, mitigation, and enhancement of fish and wildlife to the extent affected by development and operation of FCRPS projects consistent with the Northwest Power and Conservation Council (Council) fish and wildlife program, the Councils power plan, and the purposes of the Act, which includes assurance of an adequate, efficient, economical, and reliable power supply. Therefore, contrary to the comments broad assertion, the Northwest Power Act does not make Bonneville responsible for funding the regional effort to recover wild salmon and steelhead. Regarding orca recovery, the EIS analysis found only a negligible to minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). Moreover, the comments suggestion that approximately $33 billion in ratepayer funding has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System (FCRPS) 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. NW. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish). Considering hydropower costs and values of the lower Snake River dams, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90% of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $156 million and $417 million and the benefit-cost ratios are between 2.9 and 6.1. If the generation could be reliably replaced with short-term wholesale market purchases (see Table 3-170 of the Draft EIS), the lower bound for net benefits would fall to $57 million and the benefit-cost ratio would fall to 1.7. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the FCRPS and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review , the Headwater/Lower Snake Asset Class is forecast to have a 50-year levelized cost of generation of $11.41/MWh based on the direct funded capital and expense programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRPS capital and expense spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes directed funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
4696	1	will.e.putnam@gmail.com	N/A	But from what I've gathered about these dams, based on the benefit to cost ratio being far below one, I've read that the cost to benefit ratio of the four lower Snake River dams is point one five. It's actually a fiduciary duty of the U.S. Army Corps of Engineers to put those dams on non-operation status. And if that happens, then that's it. I'm afraid that that's not going to happen in time for us to save the orcas. I'm afraid that's not going to happen in time for us to save the salmon. But it seems like, regardless of those concerns, it seems like that's going to happen. It seems like because these dams are not providing the benefits that we're -- in relation to spending, it seems like they are going to get shut down. So it seems like this opportunity we have for everyone to get what they want, for the wildlife advocates to get what they want and for farmers and shippers, people working the barges, et cetera, on the river, for us all to get what we want, the lifetime of this opportunity is rapidly diminishing. And I would like to see the money that's currently being	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.

				wasted on fish mitigation, the hundreds of millions of dollars, if not billions at this point since this — EIS came out. I would like to see that money being spent to help farmers and others.	
4697	1	Randy Friedlander	N/A	The next one is just a, I guess just a tribal thing. Maybe you guys can work on the language a little bit. Noticed in your executive summary it talks about all the tribes have ceded their lands. So I guess if you take a look at executive order versus treaty tribes --treaty tribes expressly ceded their lands, executive order tribes did not. Also, you have verbiage that says something to the effect that some tribes through treaties retain the right to hunt and fish on their usual and accustom areas. Again, that's referring only to treaty tribes. The Colville tribe is an executive order tribe that does retain rights on some of its, or we say all of our usual and accustom areas. And we do have cases where those rights have been expressed or they are known, I guess. So anyway, just wanted to see if you can correct that verbiage.	Thank you for bringing this to our attention. This information in the Executive Summary has been reviewed and corrected, as appropriate in the Final EIS.
4697	2	Randy Friedlander	N/A	The first comment is just really on the process in the midst of the global pandemic with the coronavirus U19, I just thought it would be important to note that the amount of time to be able to sufficiently give you good comments on any additional changes that have been done could be -- is a little more difficult at this time.	Thank you for your comment.
4697	3	Randy Friedlander	N/A	And then the next comment is, if you could, can you tell me how you all have taken previous comments submitted by the Colville Tribe and incorporated those? It'd be helpful to know if there are specific points that you guys have heard us loud and clear and you made some adjustments, especially considering the amount of time available and the, I think around a 5,000-page document.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 and the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by resource.
4698	1	William Barquin	N/A	This is Billy Barquin of Kootenai Tribe of Idaho. So the Kootenai Tribe may be submitting written comments, we were also a cooperating agency. But I do have to make one statement about this call. I was under the understanding that we were going to have a dialog with the federal officials between the tribes and the fed as part of this meeting. I didn't know it was just really going to be speaking into a recording. So with that, I guess the question is how we're going to handle government-to-government consultation and an actual dialogue about this process and about this EIS.	The tribal-only comment meetings for the Draft EIS were scheduled on the same day as the public comment meetings using the same format as the public meetings. The purpose of these meetings during this phase of the Draft EIS was to take testimony. This was explained in the notices for both the public meetings and through direct emails sent to tribal representatives for the tribal-only meetings. While originally planned as conventional in-person public testimony meetings, all meetings were converted to phone conference only due to the COVID-19 pandemic.
4699	1	Whitney Fraser	N/A	I am a contractor working for the Confederated Tribes of the Colville Reservation. I have one fairly specific comment, which is that the topographic information, bathymetric information used for Lake Roosevelt, is referenced in a few places as being 1974 measurements, and there was an updated bathymetric survey done and released by the Bureau of Reclamation in 2010, that I previously commented we would like to see that used instead of the older information. But it didn't seem to be updated in this draft. So I would like to continue that as a comment.	The EIS used the best available topographic surface for Lake Roosevelt. This best available surface (often referred to as 2010-11 reservoir topography) was generated from a 2010-11 bathymetric data set supplemented with 1974 aerial photogrammetry, 2007 bathymetry of the upper reservoir, and 2009-10 Light Detection and Ranging (LiDAR) surveys. The older 1974 dataset was developed from photogrammetric data when the water level was drafted to an elevation of 1161 feet during construction of the third powerhouse at Grand Coulee Dam. The 20102011 bathymetric survey noted by the commenter was collected by Reclamation (Ferrari, RL. 2012) using multibeam transducers to collect underwater data between water surface elevation 1,260 and spilling elevation 1,290 (project datum in feet), and coarser single-beam equipment in shallower regions and coves. The 2010-11 bathymetric data was the first detailed bottom information of the deeper portions of Lake Roosevelt, below elevation 1,160. Additional LiDAR data for the reservoir perimeter was collected in 2009-2010 at a pool elevation of 1290 ft. The LiDAR survey covered the majority of the Columbia River reach of Lake Roosevelt, but only a small portion of the Spokane River arm. For the reservoir areas not covered by the 2010-11 bathymetric data or 2009-2010 LiDAR data, such as the Sanpoil River across from Keller Ferry and the upper Spokane River, the 1974 data were used to complete the topographic surface. The storage reservoir diagram used for the hydrology and hydraulics reservoir operations modeling and calibration for the run-of-river modeling does utilize this newer data. EIS text has been clarified in River Mechanics Section 3.3.2.3.1.4.
4700	1	Amelia Marchand	N/A	My name's Amelia Marchand. I'm a Colville Tribal member residing on the Colville Reservation in the town of Elmer City right next to Grand Coulee Dam. I'd like to reiterate all the comments that were previously provided. One, it was my understanding that this was going to be a dialogue between the federal agencies and the various federally recognized tribes involved.	The tribal-only comment meetings for the Draft EIS were scheduled on the same day as the public comment meetings using the same format as the public meetings. The purpose of these meetings during this phase of the Draft EIS was to take testimony. This was explained in the notices for both the public meetings and through direct emails sent to tribal representatives for the tribal-only meetings. While originally planned as conventional in-person public testimony meetings, all meetings were converted to phone conference only due to the COVID-19 pandemic.
4700	2	Amelia Marchand	N/A	Two, that this process is a little bit concerning, given the issues going on not just locally on my reservation within my region of Washington, Idaho, and Oregon, but nationally and internationally as well because of the COVID-19 pandemic.	While originally planned as more conventional and familiar in-person public comment meetings, all meetings were converted to phone conferences due to the COVID-19 pandemic, social distancing and public health considerations.
4700	3	Amelia Marchand	N/A	Two (sic), I also wanted to reiterate the request to have the bathymetric information that was most recently updated by the Bureau of Reclamation in 2010, to be included as the topographic information. And I think that that also goes to show that some of the comments that tribes have submitted, in particular the Colville Tribe, have not been incorporated into the document, which is a concern.	The EIS used the best available topographic surface for Lake Roosevelt. This best available surface (often referred to as 2010-11 reservoir topography) was generated from a 2010-11 bathymetric data set supplemented with 1974 aerial photogrammetry, 2007 bathymetry of the upper reservoir, and 2009-10 Light Detection and Ranging (LiDAR) surveys. The older 1974 dataset was developed from photogrammetric data when the water level was drafted to an elevation of 1161 feet during construction of the third powerhouse at Grand Coulee Dam. The 2010–2011 bathymetric survey noted by the commenter was collected by Reclamation (Ferrari, RL. 2012) using multibeam transducers to collect underwater data between water surface elevation 1,260 and spilling elevation 1,290 (project datum in feet), and coarser single-beam equipment in shallower regions and coves. The 2010-11 bathymetric data was the first detailed bottom information of the deeper portions of Lake Roosevelt, below elevation 1,160. Additional LiDAR data for the reservoir perimeter was collected in 2009-2010 at a pool elevation of 1,290 ft. The LiDAR survey covered the majority of the Columbia River reach of Lake Roosevelt, but only a small portion of the Spokane River arm. For the reservoir areas not covered by the 2010-11 bathymetric data or 2009-2010 LiDAR data, such as the Sanpoil River across from Keller Ferry and the upper Spokane River, the 1974 data were used to complete the topographic surface. The storage reservoir diagram used for the hydrology and hydraulics reservoir operations modeling and calibration for the run-of-river modeling does utilize this newer data. EIS text has been clarified in River Mechanics Section 3.3.2.3.1.4.
4700	4	Amelia Marchand	N/A	And the last couple comments are pertaining to the executive order 12898, which is the Environmental Justice Executive Order, and Executive Order 13007, the Indian Sacred Sites Order. And to that, I'm going to read some statements. In 2003, the United Nations Educational Scientific and Cultural Organization, known as UNESCO, adopted a convention for the safeguarding of the intangible cultural heritage. Intangible cultural heritage, or ICH, is defined by UNESCO as the practices, representations, expressions, knowledge, skills as well as the instrument, objectives, artifacts, and cultural spaces associated therewith, that communities, groups, and, in some cases individuals recognized as part of their cultural heritage. It is transmitted from generation to generation, constantly evolved by communities and groups in response to their environment, interactions with nature and unique histories, and provides identity and continuity. ICH includes, but is not limited to, oral traditions and expressions, including language as a vehicle of ICH, performing arts, social practices, rituals, and festive events, knowledge and practices concerning nature and the universe, and traditional craftsmanship. The most common terminology used to express ICH by indigenous people is traditional knowledge, or TK. TK broadly refers to indigenous ways of knowing that both guide and result from their community members' close relationships with and responsibilities towards the landscapes, waterscapes, plants, and animal that are vital for the flourishing of indigenous communities. They're transmitted primarily through intergenerational oral tradition and physical practices. This place-based knowledge grounds members of the society and its deep understanding of humanities rule and specifically their cultural groups and their individual role in the world. Because the knowledge is transmitted through multiple generations, it contains thousands of years of knowledge and is cumulative of evolving adapted long-term observations and technologies. World views provide a point of reference for how knowledges and, therefore, values are transmitted throughout the society system. Indigenous world views are holistic in nature, mimicking symbiotic and reciprocal relationships throughout their society structure. By contrast, the world view of Western colonialists maintains compartmentalized sectors with only give-and-take relationships of benefits and gains. Article 1 of the UNESCO Convention identifies its primary purpose to safeguard ICH, while it's second is to ensure respect for ICH of the communities, groups, and individuals concerned. In 2015, Ethical Sensibles for Safeguarding ICH were adopted by the convention's intergovernmental committee and were intended to serve as a basis for the development of specific codes of ethics and tools adapted to local and sectoral conditions. Importantly, the convention recognizes that globalization and social transformation provides avenues for intolerance to grave threats of deterioration, and the disappearance and destruction of ICH around the world. In developing the Ethical Sensibles for Safeguarding ICH, the convention identified nine threat categories. The first, negative attitudes. The second, demographic issues. The third, decontextualization. The fourth, environmental degradation. The fifth, weakened practice and transmission, followed by cultural globalization, new products and technologies, loss of object persistence, and economic pressure. The convention also identified 46 different risks to ICH, which were each placed within one of the threat categories. None of these threats or risks address the imperialist and colonialist roots of the Western world view, which results with the systematic and institutional exclusion of indigenous values and knowledges. Additionally, none of the threats or risks address the capitalism and globalization impacts of the Western world views legal, social, and political framework against indigenous people. This results with the collective destruction of indigenous heritage, identity, ownership, governance, religion, and, ultimately, exclusion and removal. And this is where I need to point out that the preferred alternative as the draft is written right now is believed to not cause disproportionately high and adverse effects on any environmental justice populations. And the draft identifies that the impact to (indiscernible) within the preferred area location are insignificant or unimportant. This is a significant concern to myself and to several other tribal members of my family and friends. Impacts to our food and water system, such as access and availability, purity, and diversity, continue to be impacted by the CRSO operation. Impact to our sacred sites, including legendary landscape, food, water, medicine, and mineral sources, as well as our graves, sacred and ceremony sites continue to be impacted by the CRSO operations. The rites and practices of life and death in our tribal communities continue to be impacted, including those associated with birth, maturity, transitions, and passing, decision-making, conflict revolution – conflict resolution and communication, and well as familial ties and governance responsibilities within our tribal communities; those continue to be impacted by the CRSO operations. Additionally, our art texture and technology, our	The co-lead agencies understand the concern regarding the continued impacts of the CRS on intangible cultural heritage, traditional knowledge, and other tribal interests. The co-lead agencies appreciate the unique connection between tribes and the Columbia River Basin ecosystems and recognize the difficulty in fully communicating these connections in the context of the EIS. In order to ensure tribal interests were represented as accurately as possible, Appendix P presents first-hand tribal perspectives that were provided by 11 tribes on the operations and maintenance of the Columbia River System, and the effects it has had on tribal life for consideration in the EIS. Section 3.17 summarizes these perspectives on the importance of the Columbia River Basin resources and landscapes to tribes and the potential impacts of the CRSO EIS alternatives. In addition, where applicable or pertinent, for specific EIS resources, the EIS described how tribal interests would be impacted by the different Multiple Objective Alternatives in Chapters 3 and 7. As the commenter notes, based on the analysis presented in the EIS, the Preferred Alternative is not expected to have a disproportionately high and adverse effect on low income populations, minority populations, or Indian Tribes. This is due to the expected magnitude of the effects of the Preferred Alternative in comparison to the No Action Alternative.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				traditional knowledges associated with those, including adaptive education, our place-based history, and our sustainable requirement resilient architectures and technologies continue to be impacted. Time and again, we collectively and cumulatively report the negative impacts of imperialism, colonialism, capitalism, and globalization to our heritage, identity, culture, values, life ways, environments, and bodies. Unfortunately, I recognize that this framework will not resolve any of the concerns I continue and others continue to bring forward, not in reporting these things, mitigating, reprimanding, holding accountable or suspending these activities. What needs to be known is that this is a staggering lack of accountability not just for the federal government but for all imperialists, colonialist governments. And these are actually acts of cultural genocide because they are threatening and risking indigenous heritage and identity and the intangible cultural heritage of communities. I hope that this information does not fall of deaf ears. I appreciate the opportunity to comment and I look forward to the best for all of us. Thank you	
4702	1	Keith Kutchins	N/A	Tonight I'd like to talk about the electricity production and try to elucidate a little bit of fact that might be skewed in this analysis. Justification of the four lower Snake dams are essential because of their flexibility in producing electricity for peaking and for filling gaps and load demands contradicts the congressionally-mandated purpose of the dams. Only 5 percent of their purpose is mandated for electricity production. Conversely, 80 percent of their purpose is to provide commodities transportation via barging, to make ocean ports far inland along the lower Snake River, culminating at Idaho's only ocean port corner, 65 miles from the ocean at Lewiston. Congress wouldn't approve these four dams at first because the only purpose was for navigation. So finally, Congress did end up mandating that 80 percent of the purpose is for navigation, which is a very heavily skewed unilateral purpose that was rare by the congressional standards of the late '60s and early '70s. By that time, Congress had started to only authorize multipurpose projects, 20 percent navigation, 20 percent recreation, 20 percent irrigation, 20 percent electricity, and flood control. But no, not these dams; 80 percent navigation, only 5 percent for electricity. I felt profound sadness and guilt when I learned yesterday from the Nez Perce traveler during this hearing when he said the then Governor Cecil Andrus lamented the coming end of the wild Idaho salmon in his comments at the ceremony commemorating the 1975 Bicentennial. Some folks saw this coming with the authorization of the dams and appropriation. Anyway, back to my point. Only 20 percent of the congressional mandate for the four lower Snake dams is for recreation, irrigation, electricity production. Bypassing the four dams which provide recreation opportunities that would equal or exceed existing levels. Existing irrigation on the lower Snake River is all pumped water that could still be provided by simply extending the pumps from the (indiscernible) river pool, the natural river lowers with no loss of irrigation -- the entire 35,000 irrigable acres. The flawed draft EIS should be corrected so that the importance of electricity produced by the four lower Snake dams is based on fact. Fact, only 5 percent of the congressionally-mandated purpose of the four dams is for electricity production. Fact, the dams combined generation capacity is only 5 percent of the Columbia River Power system. And the EIS needs to consider the percentage of total electricity produced in the EIS project area, not just the portion of the Federal Columbia River Power System, but the entire Columbia River power system. And, again, that 5 percent is capacity when its real production is 1.8 to 2.6 production. This small amount can very economically be replaced with conservation to help the river production.	The comment is incorrect in suggesting that the four lower Snake River dams' power is unnecessary for regional power needs. Bonneville sells power from the Federal Columbia River Power System (FCRPS) as a unified system, not from specific projects. In this regard, the power generated from the four lower Snake River dams are pooled with all other FCRPS power sold by Bonneville to meet Bonneville's collective power obligations. Most of this power is used to meet the loads of regional publicly owned utilities, such as municipalities, rural utilities, and public utility districts under long-term power-sales contracts (see Draft EIS Section 3.7.2.5 Bonneville Power and Transmission Customers). A small portion of power is sold in the California energy market when there is surplus, but these sales are not from specific projects, but rather from the collective FCRPS. This EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. MO3, Region C discussion begins on page 3-1267 line 3244 in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement, which concluded that modifying the existing pump system was cost prohibitive. As discussed in Section 3.12.3, for MO3, in Region C this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres. The four lower Snake River projects currently support 2.6 million visitors and $24.5 million in social welfare value annually. Breaching the four lower Snake River dams would have both beneficial and adverse effects on recreation. Dam breach would preclude reservoir recreation during and shortly after the breach, eliminating reservoir recreation; over time, and as recreation areas and access are redeveloped by others, long-term beneficial effects to river recreation, including angling, are anticipated. Section 3.11 of the EIS describes that the visitation in the long-term in the lower Snake River would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting jobs, income, and tourism businesses. No Federal mitigation is anticipated under MO3 to maintain access to the river. Since the lower Snake River projects would be deauthorized, Federal agencies would no longer operate the project lands for recreation. After project lands have been transferred to other agencies or entities (or both), and recreational sites and associated facilities could be modified as determined by others.
4704	1	Sean O'Leary	Northwest Energy Coalition	We're glad the DEIS assessment of MO-3, the dam removal alternative, confirmed the ability of new renewable resources and customer site resources to reliably replace the power and grid services currently provided by the dams. However, the DEIS analysis greatly overestimates the cost and the amount of new generating resources required to do so. This exaggeration of costs and resources arose because, first, the DEIS makes several inaccurate assumptions regarding the cost to replace -- or to acquire the replacement resources. It also assumes an impractical and wholly arbitrary implementation date of the year 2022. Then, in considering replacement resources, it failed to consider the full range of available technologies, including wind power and additional demand-side and storage resources. It also assumes the EPA will shoulder the full cost of power replacement and that these costs will be recovered only from public utility customers. In addition, the DEIS assessment fails to meet even the minimum standards to which utilities and the Northwest Power and Conservation Council adhere when they do resource planning. Under that standard, the DEIS should have first examined energy and capacity needs and resource costs over a span of years rather than just as a snapshot of the year 2022. Second, it should have fully explored demand requirements and resource options. Third, it should have tested and optimized combinations of those options. Then it should have considered the interaction of the federal Columbia River System resources with the Western Regional resources and markets, and it should have analyzed the cost incidents of the replacement alternative to determine how costs would have been allocated among Northwest customers. Had the DEIS done these things, the projected cost of the clean power replacement scenario would come down in concert with ongoing declines in costs for wind power, solar power, and storage. The amount of required replacement power would have been significantly reduced because demand response and energy efficiency would have made a far larger contribution. The enhanced cost efficiency of the replacement resources would have further reduced costs. And the cost of power replacement would have been shared by public and private utilities, thereby reducing the impact on a per-customer basis. We're especially disappointed that the energy replacement analysis within the dam removal alternative has these shortcomings because the DEIS shows it's the only alternative that restores return rates to the level required to restore the endangered species.	The comment is correct that the EIS considers a renewable replacement portfolio under MO3. The EIS used the most recent data from the Council's Seventh Power plan and Mid-term Assessment to analyze regional reliability, the need for replacement resources, the costs of those resources, and the potential for additional energy efficiency. The Councils Seventh Power Plan was issued in February 2016 and the Mid-Term Update was issued in February 2019. However, the cost of this portfolio is quite large, and the EIS did not assess the availability of integration services for such a large fleet of variable renewable energy. The implementation date of 2022 was used in the power analysis to be consistent with the implementation date used by the cost and implementation analysis. Rather than speculating on how soon the dams could be breached, the EIS focused on the process of breaching the dams and the conditions expected following dam breaching, and thus analyzed dam breaching as beginning with completion of the EIS. For hydropower, the analysis focused on the difference between the No Action Alternative and the condition after dam breaching, where the exact year of breaching is not important. See EIS Section 3.19 and Appendix Q for additional discussion of the rationale for this date. Contrary to statements in the comment, the EIS considered both wind and storage options. The EIS examined the full range of resources defined as primary by the Northwest Power and Conservation Council. This included solar, wind, natural gas, batteries, demand response and combinations of solar and wind. See Draft EIS, Section 3.7.3.5, Replacement Resource Options, pages 3-907-3-910. For all portfolios, the most cost effective was natural gas and the most cost-effective renewable option was solar. See Draft EIS, Section 3.7.3.5, Potential Replacement Resources and Associated Costs, pages 3-904-905. Also, in response to commenters suggestion that additional energy efficiency and demand response would have reduced the cost of the resource portfolios, the EIS assumed that all cost effective conservation was achieved in MO3. See Draft EIS, Section 3.7.3.1, Demand Response, pages 3-836-838. Wind was not selected because of its lower reliability benefit to cost ratio as described in Appendix J. The comment suggests that the EIS only considered Bonneville public power customers as financing the costs of replacement resources for the four lower Snake River dams. That conclusion is inconsistent with the analysis in the EIS. The EIS evaluated the costs of replacement resources assuming two different sources of financing: (1) Bonneville; or (2) regional utilities. See Draft EIS, Section 3.7.3.1, Step 3 Determine Need For Potential Replacement Resources and Associated Costs, pages 3-821-22. The power rates analysis for each Multiple Objective alternative (MO), including MO3, evaluates the power rate impacts for replacing the four lower Snake River dams using both financing assumptions. See Draft EIS, Section 3.7.3.5, Electricity Rate Pressure, page 3-918 (Bonneville finances), Table 3-166, 3-925, Table 3-167. The rates analysis also models the full impact and distribution of rate and socioeconomic effects across the affected area. See EIS, Section 3.7.3.5, Social and Economic Effects of Changes in Power and Transmission. The comment also mentions that costs would be allocated to EPA - no power replacement costs are allocated to the Environmental Protection Agency. The EIS uses high quality information as well as industry standard models to determine the potential power system effects. See Draft EIS Section 3.7.2.2; Appendix H Power and Transmission, at Section 2.1; Appendix I Hydroregulation, Section 2.4.4. The commenter suggests or questions why a competitive resource review, also known as an integrated resource plan (IRP), was not performed as part of the EIS analysis. An IRP is a resource planning tool that utilities use to plan for future resource builds and acquisitions to fulfill the utility's specific needs over a certain planning horizon, typically 20 years. Some utilities are required to conduct an IRP by their local or state utility commissions. Bonneville is not required to perform an IRP, but does perform resource planning to inform its decisions, including for this EIS. There are many different methods and tools that are used by utilities when performing an IRP. Furthermore, the output of an IRP is often driven by state energy policies, such as carbon emission requirements. Even if an IRP optimizes resource portfolios, the real costs of that portfolio are not known until a competitive request for proposal solicitation can be completed and evaluated. As explained in the EIS Chapter 3, Section 3.7.3.1, Base Case Methodology and Cost Sensitivities Analysis, the EIS analysis evaluates the power impacts of the MOs on regional power system reliability, as measured through loss of load probability (LOLP). The regional scope of the EIS is necessary because the impacts of the MOs on power system reliability and costs transcend individual utilities and states. Thus, for example, the EIS addresses the cost impacts of replacement resources for each MO regardless of whether Bonneville pays for the replacement resources. If Bonneville does not replace the lost capability caused by an MO, regional reliability would still be worse than the No Action Alternative and above the Northwest Power and Conservation Councils (Council) 5 percent standard, leaving other regional utilities to acquire the necessary resources. The EIS addressed the regional nature of the costs and resources needed to maintain power system reliability under the MOs. The EIS analysis looked at all potential resources as identified by the Council. Specifically, the EIS used data from the resources in the Councils Seventh Power Plan (2016) and Mid-Term Update (2019) to develop various resource portfolios. The cost of batteries came from more recent utility IRP data from 2018 and 2019 instead of 2013 data used in the Councils Seventh Power Plan. Seven trial resources portfolios, one carbon and six carbon-free were produced for each MO and then ranked based on their ability to cost-effectively reduce the loss of load probability (LOLP). From these portfolios, the EIS identified the two least-cost portfolios that reduced LOLP to the No Action Alternative levels. These least-cost portfolios include a (1) conventional resources (natural gas), and (2) a least cost portfolio using zero-carbon resources (primarily solar). These resource portfolios represent a range of least-cost resources that could be available to restore regional reliability to the No Action Alternative level. Based on responses to public comments, the Final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. (See Appendix H, Section 2.2 and Chapter 3, Section 3.7.3.1 in the Final EIS). Based on the fish analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
4705	1	Whitney Neugebauer	N/A	The DEIS under-represents the importance of Columbia-basin salmon in the diet and fitness of endangered southern resident killer whales. These whales need salmon from a variety of river systems throughout the entire west coast. They cannot depend on the three river systems or seasonal periods of abundance to provide adequate prey resources. Southern resident killer whales spend over half of the year in coastal waters. During that time, Columbia-basin salmon comprise over half of their diet. These spring chinook are of particular importance for southern resident killer whales. We'll follow up with additional written comments providing sources of scientific information that were not cited in the DEIS. Dam breaching, or the MO-3, give salmon the best chance of recovery of the alternatives presented in the DEIS. However, agencies should also consider another option to breach the four lower Snake River dams and utilize spill at the Columbia River dams up to 125 percent TDG. This results in the best scenario for salmon recovery. This management option is outlined in detail as the MO-3/4, alternative, proposed by the Fish Passage Center in Chapter 2 of their Comparative Survival Study 2019 report.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The final EIS in Vegetation, Wetlands, Wildlife,and Floodplains (Section 3..6.2.6 and Table 3-102), and Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and the potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. Two of those objectives are directed at salmon and steelhead. Additionally, the CRSO EIS evaluated spill at ranges from 125 percent to 110 percent Total Dissolved Gas (TDG) across the alternatives including under MO3 which includes the measure to breach the four lower Snake River dams, where 120 percent TDG spill was evaluated at the four lower Columbia River dams. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3 and MO4, by contrast, have significant regional economic and community effects, and meet fewer of the EIS objectives. Thus, the co-lead agencies did not recommend MO3 or MO4 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Thus, an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125 percent TDG at all four lower Columbia River dams is unreasonable given the unacceptable risks to public safety from such an alternative. For example, for impacts to Power and Transmission, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
4706	1	N/A	N/A	So I want the federal agencies to address the Columbia River system in a two-tiered process. Tier 1 is an emergency response action for the immediate drawdown and breach of the Lower Granite and Little Goose dam, followed by the remaining two dams in subsequent years. Tier 2 is addressing system operations and further mitigation activities in the rest of the Columbia River basin using the new EIS, assuming that the four lower Snake River dams are breached.	The agencies would have to seek congressional authority and appropriations for breaching the four lower Snake River dams and could not immediately breach the dams. The ESA does not require the co-lead agencies to take affirmative actions to support recovery of ESA-listed species. The EIS evaluated under MO3 removal of the earthen embankment of the four lower Snake River dams (referenced as tier 1 in the comment) including operations (referenced as tier 2 in the comment) of the other ten Federal dams in the Columbia River System and mitigation for effects to resources from implementing this alternative.
4707	1	rosenbergjohn@comcast.net	N/A	A reasonable person might think that after five rejections by the federal court, each more scathing than the previous one, the agencies might consider a different approach. However, they seem to be so locked into preserving the status quo that apart from minor tinkering, they keep producing the same worn-out plan over and over again. Something needs to change if Columbia and Snake River salmon and steelhead are to survive. The urgency has never been greater. Not only are salmon and steelhead threatened with extinction, but so are the orcas that depend upon them as a primary food source; so are coastal communities in Oregon and Washington that depend upon them as a primary source of income; so are the outfitters in Idaho that depend on abundant salmon and steelhead for their livelihood; so are tribes who have a treaty right to catch salmon and steelhead and for whom they are integral to their self-understanding and way of life. The only economic impacts the draft EIS takes into consideration are to the barging industry, a small number of farmers who rely on the Snake River for transportation and irrigation, and utilities who are rapidly developing alternative energy sources to replace their need for power from the four dams on the lower Snake.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For MO1, MO2, MO4, and the Preferred Alternative, the recreational fishing evaluation describes the impacts by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish, modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. The overall health and condition of the Southern Resident killer whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. National Marine Fisheries Service (NMFS) and Washington Department of Fish and Wildlife (WDFW) have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NMFS and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. SRKW also are known to eat some steelhead, coho, and chum salmon, halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKW are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKW feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon Smolt-to-Adult return rates would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). Therefore, there may be short-term adverse effects to the SRKW population as the lower Snake River wild salmon populations adjust to changes associated with dam breaching. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKW, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKW. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. Additionally, MO3 is not likely to adversely affect the SRKW distinct population segment in the short-term analysis because increased hatchery production and the new trap and haul facility at McNary proposed for MO3 in Chapter 5 would address any potential short-term impacts. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. Section 3.15, Fisheries and Passive Use Section and, in particular, Section 3.17, Indian Trust Assets, Tribal Perspectives, and Tribal Interests, include discussions of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in Section 3.15.2.1, Fisheries and Passive Use, which includes subsections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries.
4707	2	rosenbergjohn@comcast.net	N/A	I have a master's degree in Pacific Northwest History from Portland State University, where the subject of my research was Columbia and Snake River salmon and steelhead. Someone said that one definition of insanity is to keep repeating the same action over and over and expecting a different result. By that definition, the latest draft EIS could be fairly described as an exercise in insanity. A reasonable person might think that after five rejections by the federal court, each more scathing than the previous one, the agencies might consider a different approach. However, they seem to be so locked into preserving the status quo that apart from minor tinkering, they keep producing the same worn-out plan over and over again. Something needs to change if Columbia and Snake River salmon and steelhead are to survive. The urgency has never been greater. Not only are salmon and steelhead threatened with extinction, but so are the orcas that depend upon them as a primary food source; so are coastal communities in Oregon and Washington that depend upon them as a primary source of income; so are the outfitters in Idaho that depend on abundant salmon and steelhead for their livelihood; so are tribes who have a treaty right to catch salmon and steelhead and for whom they are integral to their self-understanding and way of life. The only economic impacts the draft EIS takes into consideration are to the barging industry, a small number of farmers who rely on the Snake	The CRSO EIS documents the assessment of benefits and impacts of changes to the operations of the 14 Federal projects of the Columbia River System. Using a multi-disciplinary approach and with the coordination and consideration of our cooperating agencies and Tribes, as well as public stakeholder input, and by using current, high quality information, the co-lead agencies developed the Preferred Alternative. This alternative best meets the purpose and need for the system operations in the region, as well as meets most of the objectives of the EIS in consideration of changing operations. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				River for transportation and irrigation, and utilities who are rapidly developing alternative energy sources to replace their need for power from the four dams on the lower Snake. If we want a different outcome, Congress needs to take the process out of the hands of federal agencies who have repeatedly demonstrated their unwillingness to take the necessary steps to address this crisis. Instead, Congress should give it back to Pacific Northwesterners who can come up with real solutions; sovereign tribes, all stakeholders, not just barge operators, farmers and utility executives, and regional citizens who can craft inclusive creative solutions that are lawful, science-based, and address the concerns of the people of the region today, and not just the open river boosters who promoted the dam 70 years ago. If we want different outcomes – – we need a different process with different players. If the Corps of Engineers, the Bureau of Reclamation and BPA have demonstrated anything over the past 30 years, it's that they're incapable of addressing this crisis in a meaningful way.	Moreover, the co-lead agencies disagree the Preferred Alternative is a continuation of the status quo. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The Preferred Alternative also includes other operational, structural and mitigation measures to improve conditions for ESA-listed salmon and steelhead. The EIS recognizes the social and economic values associated with salmon although these values are not all expressed in monetary terms. Section 3.15 provides a discussion of the value of fisheries (commercial and subsistence) associated with salmon, as well as passive use values that people hold for these fish. Section 3.11 describes recreational values associated with the fish. Regarding southern resident killer whales (SRKW), the co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).
4711	1	harryrjag@gmail.com	N/A	And I've looked into the EIS – the DEIS. The best recovery is given with the MO-3, which is removing the Snake River dams. Just a few facts from the Idaho Conservation League, which talks about SARs. I'm sure most of the people that worked on the EIS knew about SARs. The Deschutes River with two dams has the SARs of 5.94. You need at least a SARs of 2 to at least maintain the population, and 4 would be better. The John Day Dam, with three dams in the way, has a SARs rate of 6.06. The Yakima River, with four dams, has a SARs of 4.58. The Snake River Basin above Lower Granite Dam, where we have eight dams, the SARs rate is 1.84.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Different models predict different long-term survival benefits to ESA-listed species from breaching the four lower Snake River dams, benefits that can contribute to recovery. Under the National Marine Fisheries Service (NMFS) COMPASS model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6 percent due to dam breach, which is a 19 percent relative increase over the No Action Alternative. The NMFS Lifecycle Model predicts an increase in adult returns of 13.6 percent for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88 percent to 1 percent). Results for Snake River steelhead are similar (10 percent absolute improvement, or 23 percent relative juvenile survival increase, Smolt-to-Adult returns (SARs) for steelhead were not modeled. Under the CSS model, juvenile in-river survival for the Snake River spring/summer Chinook is predicted to improve by 10.4 percent due to breach of the four lower Snake River dams, which is an 18 percent relative increase over the No Action Alternative, while SARs would increase by 115 percent (from 2 percent to 4.2 percent). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8 percent which is a 46 percent relative increase over the No Action Alternative. The CSS model also predicts that SARs increase by 177 percent (from 1.8 percent to 5 percent). Though differing in predictions, both models predict MO3 is the best alternative for salmon and steelhead. One model simply predicts adult return increases an order of magnitude higher than the other. With respect to the Preferred Alternative, the CSS model, which includes latent mortality effects predicts that median SARs will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. A SARs rate of 2 percent can lead to substantial population growth given adequate productivity and habitat quality. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address the uncertainty due to the different model results, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, and Total Dissolved Gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
4713	1	Caitlin Straubinger	N/A	The DEIS, in the preferred alternative, falls short of providing comprehensive solutions that address all parties. It fails our community of guides and outfitters who rely on bountiful fish returns for their livelihood. And it fails salmon and steelhead. These iconic endangered fish deserves every chance to thrive in the wild as they have for hundreds of thousands of years before we got involved. Salmon returns to the Snake and Columbia Rivers are dreadful. Current wild returns are just 1 to 3 percent of historic returns. In Idaho, that number is even lower. Scientists tell us that the single best action we can take to recover salmon and steelhead is to restore the lower Snake River by breaching the four dams. Small river towns like Salmon, Riggins and Orofino rely on outdoor recreation and fishing. Outdoor guiding and recreation in Idaho provides over 70,000 jobs and $2.3 billion in direct and indirect salaries and wages. The DEIS doesn't account for this. The DEIS should include a comprehensive economic analysis of Idaho's salmon sport fishery and its great potential should wild salmon and steelhead return in abundance. The DEIS furthers an approach that isn't working. Salmon and steelhead in the Columbia and Snake Rivers are endangered and threatened. We've spent over $17 billion on recovery, and yet wild salmon and steelhead throughout the Columbia and Snake River basins are still on the endangered species list. We need collaborative solutions that meet the needs of all interest groups in the Pacific Northwest, and DEIS and the preferred alternative, don't do this	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the MOs, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. Under MO3, the EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in Region C that would occur under a dam breach scenario as major and beneficial. The potential for increases in recreational fishing under MO3 in Region C is described in Section 3.11.3.5, which would support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The commenters suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at Federal Columbia River Power System (FCRPS) projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish). With respect to the Preferred Alternative (PA), the CSS model predicts that average Smolt-to-Adult return (SAR) rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council recovery targets for the region) as a result of the PA (increasing from 2.0% to 2.7% for Chinook, a 35% relative increase). The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The PA will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS, for additional information.
4713	2	Caitlin Straubinger	N/A	Finally, and especially in light of these unusual circumstances, the DEIS comment period should be extended. At a minimum, the comment period should be 120 days.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public, that they should plan to submit comments by the close of the comment period.
4716	1	will.e.putnam@gmail.com	N/A	Your draft EIS is missing a vital piece of context that must be included. I'm going to get into that right now. On May 4th, 2016, in a federal district court ruling, three U.S. government agencies deeply involved in the Columbia River system were found to be in violation of the Endangered Species Act and the National Environmental Policy Act. I think this can be referred to as National Wildlife Federation, et alia vs. National Marine Fisheries Service, et alia. And I want to read a portion of that, page five, from Judge Michael Simon. He states, and I quote: In this lawsuit, plaintiffs raised two primary questions. First, did defendant, NOAA Fisheries act arbitrarily and capriciously when it issued its latest biological opinion (the '2014 BiOp') concluding that the operations of the Federal Columbia River Power System do not violate the Endangered Species Act of 1973, based on the 73 'reasonable and prudent alternatives' described in the 2014 BiOp? Second, did Defendants U.S. Army Corps of Engineers and U.S. Bureau of Reclamation violate the National Environmental Policy Act of 1969 by failing to prepare an environmental impact statement in connection with their records of decisions implementing the 73 reasonable and prudent alternatives described in the 24 BiOp. The answers to both questions are yes. End quote. As it is in your draft, on the first page of your executive summary, you state – and this is the first paragraph, we prepared this document in response to the need to review and update management of the CRS. I find that that's inaccurate and that it fails to disclose the true circumstances of the inception of this EIS. The purpose of this report is to fulfill the demands of the court order that ruled against NOAA, and the Corps, and the Bureau of Reclamation. The context of this court order must be included on the first page of that executive summary as well as the full report, any explanations for making alternative decisions as well as any other conclusions. This must be included because the public and everyone who encounters this report, including employees and contractors of these federal agencies, they all need to know whether the actions based on this report are in continued violation of the laws of which these agencies were previously found to be in violation. By failing to disclose those ongoing violations and the court order, this EIS hides the criminal negligence, if not criminal recklessness, of NOAA, the Corps and BOR. I would Bonneville Power to that list as well. They have all failed to rectify the violations. These agencies have published information that prove that the river system — will not reduce the damage to salmon and other endangered species. I propose the need for an unbiased third-party team of experts, scientists of all types, biologists, environmental science and financial experts and economists to analyze the information. Otherwise, there's no government accountability here. And the need for government accountability is why DEIS started. Since this DEIS – introduced major changes, this DEIS does not rectify the criminal negligence or the criminal recklessness of the violation of both the Endangered Species Act and National Environmental Policy Act.	The co-lead agencies take all legal and NEPA responsibilities very seriously and disagree with the comment. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
4716	2	will.e.putnam@gmail.com	N/A	My name is William Putnam. I spoke earlier. I'm a private citizen. And I just wanted to get back on the line and add my name to the list of people that are demanding for an extension of this public comment period. In part, the purpose of this public comment period is government accountability. And I find	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				this period to be insufficient to allow for that. I just kinda want to put that in perspective a little bit. February 28 to April 13th is 46 days, but the EIS is 7,620 pages. So if you were to split that up per day, that would be 165 pages per day. And with the conservative assumption that the average page has 300 words. That's about half a page, half of a page's worth of words. And using an average of 300 words per minute as a reading speed for an adult, that comes about 2 hours and 45 minutes of reading a day, every day for 46 six days. If you want that together, the 7,620 pages would take about 126 hours. That comes to a full three workweeks – three full 40-hour work weeks with six hours of overtime. And that's three full workweeks over the course of a seven-week time period, a time period in which many Americans are struggling to maintain their normal employment due to COVID-19 pandemic, as others have said. Again, three full workweeks and that's just consuming your content here. That doesn't include the work of cross-referencing that's necessary for adequate government accountability. And as we've seen from some of the callers, there are some people out here that are making use of this time to dig into the details of this report. It seems like Jim Waddell is one of those people. Chris Pinney another. But getting back to your page numbers and specific analysis that could, and I daresay – dare I say it should be invaluable to you as retired Army Corps of Engineers that are working for you for free, if you'll take it. So this time period needs to be extended in my opinion.	determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
4718	1	John Francisco; John Francisco	Northwest Requirements Utilities (NRU)	The draft speaks extensively to concerns around the losses related to avian predation, and we must all consider what can be done to mitigate these losses and others. Every variable that contributes to lower than expected salmon and steelhead returns must be put under the microscope. Only when we all agree that every factor that contributes to salmon population is on the table for discussion, will we be able to collaboratively address salmon returns without choosing winners or losers.	The co-lead agencies agree that salmon and steelhead are important resources in the Northwest and have invested significant time and resources at the projects covered by this EIS to improve survival and adult returns. The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service website at: https://www.nwfsc.noaa.gov/research/index.cfm. As analyzed in Section 7.7.7, the Predator Disruption Operations measure could delay nesting waterbirds, forego nesting, or relocate to other areas. As discussed in Section 3.6.3.2, Caspian terns are highly mobile during the breeding season and move between breeding colonies in a given year and between years, demonstrating a willingness to nest away from the Columbia River while still foraging on juvenile salmonids (Corps 2014, 2018, 2019). As part of this projects monitoring and adaptive management plan (Appendix R, part 1), monitoring of the Predator Disruption Operations measure would determine the measure effectiveness on reducing the avian predators nesting habitat and monitor if the migratory bird species (Caspian terns) would remain at healthy and sustainable levels. Under the Preferred Alternative, those actions, including for the purpose of reducing avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
4722	1	Jill Heine	N/A	From what I can see, the DEIS, as written, doesn't represent the importance of the Columbia Basin salmon for the southern resident killer whales. They need salmon from a variety of rivers throughout the entire West Coast. They can't depend on two to three river systems or seasonal periods of abundance to provide adequate prey resources. The southern resident killer whales spend over half the year in coastal waters. Columbia Basin salmon make up more than half of their outer coast diet. Spring chinook are of particular importance for these whales and dam removal gives salmon and steelhead the best chance of recovery. This report and previous models find that breaching the four lower Snake River dams and utilizing spill at the Columbia River dams results is the best scenario for salmon and steelhead recovery. Even NOAA's own recovery plan starts with "Perhaps the single greatest change in food availability for resident killer whales since the late 1800s has to be the decline of salmon in the Columbia River Basin."	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. SRKW analysis has been done and described in the EIS, including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
4726	1	kairos42@earthlink.net	N/A	I would like to point out some specific comments in the EIS that are wildly inaccurate. First off, in terms of irrigation on page 3-1270, the EIS gives impacts for the breaching of the lower Snake dams in terms of $313 million lost land value, $232 million in lost labor income, $460 million in lost output, and a loss of 4,800 jobs. They say this because the EIS drafters accepted the 2002 EIS assumption that irrigation modifications would cost far more than the land values. While this is true, these modification estimates were revised by water supply engineers who showed that all irrigation systems on the lower Snake Ice Harbor pool can be modified with extended pipes and additional pumps for $20 million. That's correct, a $20 million fix versus a billion dollars in impact claimed in this EIS is just another egregious example of gross exaggerations. Indeed, breaching will allow reclamation of orchards, vineyards in the lower Snake Valley that existed before the dams, along with the recreation and synergistic development, such as wineries, hotels, restaurants, etc., this, according to economists, can generate 3- to 4,000, jobs, yielding $200 to $300 million in annual benefits to the six-county area in eastern Washington along the Snake. This DEIS has this one absolutely backwards.	This EIS discusses engineering solutions, including pipeline extensions, in Section 3.12.3. MO3, Region C discussion begins on page 3-1267 line 3244 in the Draft EIS and is also found in Appendix N. The EIS draws upon the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement which, concluded that modifying the existing pump system was cost prohibitive. As discussed in Section 3.12.3, for MO3, in Region C this analysis assumes that pumps are unable to deliver water to an estimated 47,926 acres. There is a physical limitation to delivering water to these lands in the absence of the dams. Breach of the dams has the potential to drop surface and groundwater levels up to 100 feet and it is not possible from an engineering or cost standpoint to replace the delivery mechanisms, nor do the co-lead agencies have the authority to do so currently.
4726	2	kairos42@earthlink.net	N/A	Another area, transportation. MO-3 breach impacts that indicate the rail rates will increase by 50 percent are not based on any kind of modeling or transportation movements. And I talked to a Corps of Engineers planner today that I verified this with. But what they did is they basically both based these increases on opinions from a few individuals. This wonky, unprofessional set of assumptions leads to a fatally flawed impact. The DEIS further says there is a concern over lost — (inaudible) while not a legitimate rationale according to engineer planning guidance. There are two Class I railroads, five	How rail rates would change without lower Snake River shallow draft barging cannot be known with certainty. Therefore, to evaluate the impacts of potential rate increases, a range of rail rate increases are evaluated, from 0 to 50 percent. As the modeling effort shows, if rail rates are not increased, freight volume would likely exceed current capacity, which would put upward pressure on rail rates. If rail rates increase by 50 percent, truck transport would be relatively attractive to shippers, which would put competitive pressure on rail companies not to increase rail rates much higher. As such, the modeled range of increased rates appears reasonable.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				short lines, and the infrastructure is supported by the state of Washington. I think this leads, again, to the point that the impacts provided in the EIS for breaching are essentially wrong and grossly in error. And, basically, they're so fatally flawed and of such a magnitude that this makes this DEIS unusable at this point in time and it should be withdrawn immediately.	The co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as cooperating agencies, and more than 30 of those invited agreed to participate. Staff from the cooperating agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The draft EIS was subjected to two internal agency reviews by the Corps of Engineers experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available.
4726	3	kairos42@earthlink.net	N/A	This is Jim Waddell, civil engineer, former Corps of Engineers. I want to point out something about the trucking of grain. Every grain of wheat, like the lady said, goes on the truck. It starts in a truck and goes to a grain elevator someplace. And with breaching and change of barging to -- the elimination of barging, what you end up with, though, is all those grain elevators are still there. So wherever those trucks are going now, they'll pretty much go to the same place. The only difference is the grain elevators on the river, who all, but one, are served by a rail line right now, many of them can put grain on rail right now. And with some upgrades, they can handle a lot more capacity. So basically, truck traffic, theoretically, or in real life shouldn't change at all for the farmers. It's just a matter of where that grain elevator puts it. Right now, they have a choice between putting it on a barge or putting it on the railcar. And so, what will happen is, it will all go by rail. And because there's several railroads -- two main railroads, Union Pacific and Burlington Northern, you still have competitive forces going on there. Also, because the state of Washington basically supports all those short line railroads, they're not going to let rates go up if it costs the farmers. So that's an important point to get across there. And so that's the main thing I wanted to clarify on that particular point.	Much of this comment about the options for shipping wheat is correct, but the assumption that farmers would not be impacted during a dam breach scenario is incorrect. Under Multiple Objective alternative 3, which includes a measure to breach the four lower Snake River dams, a farmer's options would be more limited, and because shipping rates are higher for rail and truck, shipping costs would increase. The analysis evaluates a scenario where rail rates do not increase further under the breach scenario, and finds that the volume of freight that would move to rail would exceed shortline rail capacity in the short-term, though it could be accommodated in the long-term with capacity increases. Under a scenario where rail rates increase by 50 percent, a significant volume would move to truck and rail freight ton-miles would not increase.
4726	4	kairos42@earthlink.net	N/A	The other thing is we heard earlier the unique capability of the dams to ramp up in the morning to meet daytime peaks, that's on page 3-906 of the EIS. All the dams in the hydrosystem do that every night. They're just following load. But I'd say what is unique about the Snake River dams is their inability to ramp and provide peak power for balancing, for reserves, or just any of this kind of stuff because they're run-of-river dams. And to do that would require them to be drawn down below the minimum operating pool, which they're not allowed to do. So this is all fantastical kind of thinking on the part of whoever put this work together at Bonneville Power Administration to think that you can get these kind of power benefits out of these dams. You can't. They basically can supply what they're doing now and they're generating power pretty much all the time that they can in light of spill requirements, and that's about it. So it's a misnomer to give these unique abilities to these dams in some sort of beneficial way. They don't have -- I'm finished. Thank you.	The commenters statement that the four lower Snake River dams do not provide peaking capacity for balancing reserves is inconsistent with the findings in the EIS. While the four lower Snake River dams are considered run-of-river projects, their forebay range is large enough to allow some water to be stored for release later, though more on the scale of hours. In contrast, storage dams can store some water between seasons. With the amount of storage that is available at the four lower Snake River projects, and constrained by water conditions, they are often able to increase generation to serve loads during peak demand periods and reduce generation during low-demand periods. Likewise, the four lower Snake River dams can provide balancing reserves, particularly outside the juvenile fish passage season when they are not spilling water for fish passage and when the elevation range of operations is larger. See Draft EIS, Section 3.7.3.5, Potential Replacement Resources And Associated Costs, pages 3-904-905; and Table 3-160 (showing the sustained ramping capability of the four lower Snake River dams). Breaching of the four lower Snake River dams under MO3 would have a direct and substantial impact on the supply of Federal power to meet regional load requirements. These impacts would reduce both actual energy to meet regional load requirements and generating capacity (peaking capacity) to meet variability in loads. The four lower Snake River dams are among the most valuable projects in the Federal Columbia River Power System. These dams provide over 1,000 aMW of carbon-free energy and up to 2,000 MW of sustained peaking capacity at certain times of the year. The dams also have unparalleled ramping capability, the ability to quickly generate energy to match spikes in energy usage,with over 2,000 to approximately 2,300 MW of capability in certain months of the year. Table 3-160 of the Draft EIS presents the historical sustained ramping capability of the four lower Snake River dams. While the four lower Snake River dams are indeed run-of-river projects, upstream storage projects (Dworshak and Brownlee) regulate some of the water flowing into the lower Snake River, which flows year-round. In particular, the lower four Snake River projects produce a substantial amount of power in the winter, which is currently the region's highest demand period.
4730	1	Kristin Meira	N/A	We are concerned with some of the analysis that was performed regarding barging on the Snake River. In particular, we're concerned that only wheat shipments on the Snake River were modeled when it comes to characterizing the increased cost as well as the increased carbon emissions, which would occur if barging is taken away as a mode of cargo transport. And when you only take into account wheat shipments, you end up underestimating the transportation impacts of dam breaching by at least 38 percent. And then when it comes to capturing the air pollution impacts that would occur if the dams are breached and barging is taken away, this DEIS also only looks at truck trips as being one way, when, of course, the trucks would return empty back to the farms with carbon emissions all along the way. And in contrast with a previous caller, we believe that the real rate increases that are presented in the DEIS are actually low. As most people know, when two modes of transportation compete, rates are typically kept in check.	In 2018, 72 percent of overall freight volume on the lower Snake system traveled downriver, the majority of which (87 percent) was wheat and barley. As discussed in Section 3.10.2.1 of the Draft EIS, 28 percent of overall freight traveled upriver. In 2018, 25 percent of overall freight on the lower Snake River was petroleum products that terminated below Ice Harbor Dam. These shipments do not utilize the Snake River locks and would not be directly affected by dam breach under Multiple Objective alternative 3. Other commodities that utilized the Snake River system include pulp and paper products (4 percent) as well as chemicals and iron/steel commodities (8.5 percent), some of which also terminate below Ice Harbor Dam. To the extent that these shipments utilize the Snake River locks and dams, they would be affected under Multiple Objective alternative 3 by increased transportation costs. These potential effects are discussed qualitatively in Section 3.10.3.5.
4731	1	Bob Rees	N/A	Factually, here are some figures that should be considered when pursuing solutions to the crisis of salmon recovery in the Columbia Basin. These facts come from state agencies and an economic study conducted by the American Sport Fishing Association. In particular, mortality rates of wild spring chinook by source, hydropower kills 42 percent of wild chinook juveniles. Hydropower kills 18 percent of adults spring Chinook. Predatory birds kill 6 percent of juveniles. Predatory fish kill about 6 percent of juveniles. Marine mammals kill about 4 percent of adults. And both in river and ocean fisheries harvest about 10 percent of spring Chinook adults. Fall chinook mortality is even more telling. Hydropower kills about 88 percent of juveniles. Hydropower kills about 29 percent of the adults. Predatory fish kill about 10 percent. Predatory birds kill about 5 percent. -- kill about 2 percent. And the ocean and in-river sport and commercial fisheries kill about 45 percent. The economics of the region, sport fishing in Oregon, Washington, Idaho, counting the multiplier effect is worth about $3.8 billion and produces about 34,500 jobs in the region.	The myriad of factors that affect salmon and steelhead survival are acknowledged and described in the Affected Environment. Those factors that could be affected by the operation and configuration of CRS projects were described in the No Action Alternative analysis and then evaluated under each alternative. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. There are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service website at: https://www.nwfsc.noaa.gov/research/index.cfm.
4734	1	Kenneth Balcombe	N/A	Hi. My name is Kenneth Balcombe. I'm the senior scientist at the Center for Whale Research. We've been studying the southern resident Killer Whale since 1976 and provide our data to the U.S. government and Canadian government for their management programs. There's no question that the southern residents are following the salmon to extinction. And what we're witnessing right now is a serious lack in reproductive capability. There are probably only six females producing calves at five- to ten-year intervals. This can't go on. It's tragic that the Snake River salmon, which were the mainstay of their diet, have been characterized in the DEIS as being an insignificant portion of the food they require. Obviously, if food isn't there, you can't eat it. And the studies that have been taken on the diet of the southern resident killer whales has primarily been in the Salish Sea showing that they also eat the salmon in this region. But they spend most of their time on the coast eating the salmon from the large runs that used to be from the Columbia and Snake. It's just tragic. They have no options. And the other stakeholders here in this business do have options. And I urge just to exercise those options and get rid of those dams immediately and start the restoration of this ecosystem.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The quantity and quality of prey is one of the limiting factors identified by the National Marine Fisheries Service (NMFS) in recovery of Southern Resident killer whales (SRKW), along with vessel traffic and noise, toxic contaminants, and other health risks (e.g., inbreeding). The operation of the CRS directly affects Chinook salmon, both wild, natural and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKW. However, according to NMFS, in terms of abundance of salmon available to SRKW for prey, populations of some Snake River adults stocks are now greater than they were in the 1960s, before the four lower Snake River dams were built. NMFS scientists maintain that recovering salmon stocks for SRKW goes beyond the Columbia River Basin (CRB), and that hatcheries produce more than enough Chinook salmon in the Columbia River Basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between hatchery and wild fish. The EIS analysis in Section 3.6 (Vegetation, Wetlands, Wildlife and Floodplains) found only a minor effect to the SRKW would result from implementing MO3, which includes breaching the four lower Snake River dams, with modest long-term increases in prey, while recognizing that salmon and steelhead hatchery production contemplated under the No Action Alternative would continue. This conclusion is based on the fact that Chinook salmon available to SRKW from the lower Snake River comprises only a small percentage of their overall diet, although lower Snake River Chinook are important prey during certain times of the year. Changes to this portion of the whales food availability of the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but will not change their overall condition or population dynamics (NOAA fact sheet: https://www.nwfsc.noaa.gov/publications/documents/FAQ%20SRKW%20Factsheet%20DRAFT2%20OCT2018%20508.pdf). The Preferred Alternative (PA) has negligible effects to SRKWs as described in Section 7.7.8 in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. The co-lead agencies note the contribution to the prey of SRKWs through the continued existence of their respective independent, congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation, and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by the U.S. Fish and Wildlife Service (USFWS).
4735	1	Albert Becker	N/A	Also, one thing in the draft EIS that is very significant, is they did not recognize the recreational value of restoration of salmon and steelhead in the Salmon River drainage in the Snake River. There would be major economic benefits that has been presented earlier by Mr. Rees.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
4738	1	Shari Tarantino	N/A	This is Shari Tarantino, executive director of Orca Conservancy. First and foremost, the comment period deadline will not allow enough time for thoughtful and educated comments. Therefore, we request an extension to the current April 13th deadline.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
4743	1	Nick Calero	N/A	Right now, I want to say that the current EIS does not solve the crisis of declining runs of salmon and steelhead. A better solution and one that I've been involved with in a multitude of different states, the best solutions come about through a collaborative process and when a multitude of different stakeholders are involved. Those are the solutions that last the test of time. And I currently feel like that is not been replicated here and is a model that should be tackled here in the future with regards to this issue.	It was very important to the co-lead agencies to seek input from a wide variety of stakeholders in the region as the EIS was developed. Not surprisingly, there is a wide range of views and opinions about the best approaches to managing the CRS. However, it was also apparent that people throughout the Northwest share many common values and interests. The goal has been to develop an approach to river management that balances these multiple perspectives and can serve as a springboard to continued progress. More than 30 entities from across the region, consisting of Tribes, Federal agencies, and state and local governments, agreed to participate as cooperating agencies in this NEPA process. The co-lead agencies greatly appreciate their technical expertise and input on early versions of this document. The co-lead agencies are especially grateful to our Tribal partners for helping ensure that the document reflects tribal perspectives on the CRS. While the Preferred Alternative represents a meaningful step forward for salmon that seeks to balance the many purposes of the CRS and statutory obligations of the co-lead agencies, the co-lead agencies recognize that it will not end the debate about the future of the Columbia River and salmon. The co-lead agencies are responding to the voices calling for additional collaborative dialogue across the region about the future of salmon recovery, affordable and reliable clean electricity, and economic and cultural vitality for the tribes and other communities who depend on the CRS for their way of life. The co-lead Federal agencies will be active participants in developing solutions for achieving broader recovery objectives that address the effects of the CRS and the other key variables that impact salmon across their life cycle. The CRSO EIS is intended to evaluate options for future operation and configuration of the 14 dams in the CRS. The purpose of this EIS was not to consider ways to recover ESA-listed salmon and steelhead, though the EIS does consider options for management that may benefit fish, and evaluates effects to ESA-listed fish, as required by NEPA.
4744	1	commcomm2@gmail.com	N/A	The EIS process taking four years and $80 million justifies non-breach alternatives by presenting MO-3, or the breach alternative as the poison pill. MO-3, the breach alternative has been poisoned by including more spill structural measures and mitigation on other lower Columbia dams. Overestimated breach costs and unnecessary mitigation costs further poisoned the breach alternative. MO-3 has been falsely presented as extremely expensive. Even so, evidence in MO-3 points to breaching as the only alternative that saves money and has the highest probability of recovering salmon and orca.	The method proposed for breaching the lower Snake River Dams is based on extensive analysis completed for the 2002 Feasibility Study, which also considered dam breaching. The methodology developed is intended to minimize impacts to ESA fish runs, other aquatic organisms, the built environment, and provide maximum protection to human health and safety. The EIS uses the same assumptions. For the purposes of this EIS, the 2002 cost estimates were inflated to 2019 price levels. The co-lead agencies will continue to adhere to Federal standards for dam and levee safety and human life safety considerations. In the event that breaching of the lower Snake River dams is implemented, additional analysis will be conducted to refine methods and costs. Different models predict different long-term survival benefits to ESA listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River Spring/Summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase - Smolt-to-Adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River Spring/Summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. The EIS concluded MO3 would have greater improvement to certain salmon species in the lower Snake River. It did not conclude there was greater certainty of that result in MO3 over any other alternative. The conclusions were based on the ranges predicted in two independent models that have different parameters and limitations in their predictive capabilities. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of Southern Resident killer whales (SRKWs), along with vessel traffic and noise, toxic contaminants, and other health risks (e.g., inbreeding). The operation of the Columbia River System directly affects Snake River and Columbia River Chinook salmon, both wild and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of abundance of Chinook salmon available to SRKW for prey, populations of some Snake River adult Chinook salmon stocks are now greater than they were in the 1960s, before the four lower Snake River dams were built. NMFS scientists maintain that recovering Chinook salmon stocks for SRKW goes beyond the Columbia River Basin, and that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW. (NMFS BiOp 2020). The EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (tules and brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020).
4744	2	commcomm2@gmail.com	N/A	The economic benefits of the dams to the region have declined and operational costs have risen. The Army Corps of Engineers already spent seven years and $33 million of rate and taxpayer money on the 2002 EIS with a breach alternative. The Army Corps of Engineers has a fiduciary responsibility to cease operations and place a project into a non-operational status when the projects are losing money economically or causing unresolvable biological harm. Thus, the Corps does not need specific authorization to secure the project by breaching. The federal agencies have a responsibility to comply with the Endangered Species Act and to take action is necessary to recover endangered salmon, steelhead, and the southern resident orca population. Breaching can be paid for by BPA as the least cost way to accomplish fish mitigation under the 1980 Northwest Power and Conservation Act, and as a means of transferring savings from lower Snake River dams to other Columbia River dams.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The commenter's assertions about authority and funding are incorrect. If MO3 were selected, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the four lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species.
4749	1	Deanna Mueller-Crispin	N/A	And finally, it is unconscionable to continue with a public comment period when the entire country is struggling with and absorbed by the spread of a lethal pandemic. The comment period should be extended to allow for in-person testimony.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
4754	1	seanallen83@ymail.com	N/A	In order to have endangered Snake River salmon, southern resident orca and ratepayer money, in order to save them, the federal agencies should address the Columbia River system in a two-tiered process. Tier one is an emergency response action for the immediate drawdown and breach of the lower Granite and the lower Goose Dam, followed by the remaining two dams in subsequent years. Tier two is addressing system operations and further mitigation activities in the rest of the Columbia River basin using the new EIS, assuming that the four lower Snake River dams are breached. The two-tiered approach should be initiated for biological and economic reasons. Endangered Snake River salmon and steelhead have not recovered since the 2002 EIS was implemented, and I've gotten much worse over the last four years. Wild stocks may not survive further studies foreseen in the CRSO process. The economic benefits of the region have declined and operational costs have risen. The Army Corps of Engineers already spent seven years and $33 million of rate and taxpayer money on the 2002 EIS with a breach alternative.	The agencies would have to seek congressional authority for breaching the four lower Snake River dams and could not immediately breach the dams. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Draft EIS evaluated a measure to breach the four lower Snake River dams, in Multiple Objective alternative 3, (referenced as tier one in the comment) including operations (referenced as tier two in the comment) of the other ten Federal dams in the Columbia River System and mitigation for effects to resources from implementing this alternative.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
4756	1	Steven Pfeifer	N/A	This DEIS has ignored a crucial window of time, in which actions taken now to recover salmon will build their resilience to challenges ahead.	The EIS considered the impact of all of the actions and measures in the alternatives as time progresses from implementation into the future. The benefits of actions implemented as part of the Preferred Alternative would begin to accrue as soon as the actions are taken, many of which would occur shortly after the co-lead agencies issue the Record of Decision or would continue to accrue if they are being carried forward from the No Action Alternative.
4756	2	Steven Pfeifer	N/A	This federal report examines restoring the lower Snake River via dam breaching. It only takes a cursory glance at the immense benefits that subsequent return to abundant levels of salmon steelhead would entail. It completely ignores the sportfishing economy that is so important to guides, outfitters and small towns throughout Idaho. But also ignores the large economic impact anadromous fish in a restored section of river would have on outdoor recreation industries throughout the Northwest.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
4757	1	reputnam@gmail.com	N/A	I would first extremely advocate for a longer period of comment time, not only because of the virus, but just because of the fact that it's such a long report and full of information that needs to be really studied and sorted out as to what's true and what's not. As an engineer, I would think that this report almost needs to be rewritten. I appreciate the amount of time that's gone into this thing, but you're not giving the public commenters, us, enough time to sort it out. We were getting 3 percent of the time that you put into it to read it, to understand it. If we were to do this on a daily basis, it'd be one 173 pages approximately every day that we'd have to sort through. That's way too much for a 45 day comment period, which is the minimum for an EIS. There's no reason that we can think of that you couldn't make it longer.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
4757	2	reputnam@gmail.com	N/A	I guess, in addition, the Columbia River watershed has 60 dams, at least; 14 on the Columbia, 20 on the Snake, generating 36 megawatts. The lower salmon dams only generate about one, on average. I think there's a whole lot more that could have gone into a report like this. Alternatives, such as -- why not get rid of the dams for a period of time. Pick a decade or two where the dams temporarily breached and see what happens. It's been a 15-year experiment that hasn't been working very well so far, so why don't we try something really different?	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Your suggestion to temporarily breach the dams did not result in meeting objectives of the study is noted and would also, of course, have to be studied and effects evaluated. While the four lower Snake River dams account for a small portion of the total number of dams in the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. They provide approximately 1,000 aMW of carbon-free energy on average, enough to power about 730,000 Northwest homes, and 2,000 MW of sustained peaking capacity at certain times of the year. See draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. The dams also provide important ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907 and Table 3-160. As described in Section 3.7.3.5 of the EIS, the LOLP analysis of Multiple Objective Alternative 3, where dam breaching accounts for about 90 percent of the power impact, showed that the region would have an annual risk of power shortages of around 14 percent stemming from shortages in the winter and summer. See also Appendix J, Hydropower, Section 4.1.2.4 in the draft EIS.
4759	1	Nanette Jones	N/A	I'm supporting Chris Pinney's comments, Jim Waddell's comments tonight. I think it's absolutely imperative, too, that we allow a longer comment period on this process. So we could have more collaboration.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
4761	1	Julie Van Middlesworth	N/A	I feel that the proposed alternative does not go far enough to ensure that the native salmon and steelhead populations safe. And I would also like to state that my main concern is, of course, for the salmon and steelhead, but also for the central Idaho complex, which is comprised of the Frank Church River of No Return Wilderness, the Selway-Bitterroot Wilderness, the Gospel Hump Wilderness. And those headwaters areas are critical and one of the last intact ecosystems in the continental U.S. They are critical for other endangered species, like, grizzly bears. And the salmon and steelhead are keystone species that provide nutrients all the way in those rugged inland northwest areas. And we need the salmon back there. They're a critical link to the Yellowstone to Yukon corridor. And it not only affects threatened and endangered salmon, but grizzly bear and, of course, I'm sure many people have said, the southern resident orca as well. So it's not just the fish, but all of the ecosystems that they support.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Grizzly bears within the Columbia River System project area do not feed on salmon as the current grizzly bear population reside above anadromy. They eat other fish, animals, as well as vegetation within their natural range as described in Section 3.6 Vegetation, Wetlands, Wildlife and Floodplains.
4762	1	Steve Weber	N/A	As I've read the draft EIS, I believe it was written with the end goal already predetermined. To the credit of the authors, they admit that MO-3, breaching the dams, would provide the best outcome for the salmon. But the rest of the report is written in a confusing way that's really meant to preserve the status quo.	As required by the National Environmental Policy Act (NEPA), the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapters 3, 4, 5, 6 and 7; summarized by resource and alternative in Table 3-1, and presented for comparison in Tables 7-1 and 7-55 in the Draft EIS. Effects specific to anadromous fish are described in Sections 3.5.3 and 7.7.4. In the Draft EIS, Table 3-61 compares expected survival by alternatives, and Table 3-62 provides a comparison of the alternatives specific to anadromous fish. The Executive Summary serves as a primer and broad summary of findings. The Final EIS expands the table of contents that was in the draft EIS to assist readers in finding specific topics. The EIS also includes an index, so the public knows where to look for detailed analysis in either the main body of the EIS or the appendices. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives, which in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.
4802	1	j.comrada@comcast.net	N/A	Since only 1 in 1,000 (.01%) salmonids return to spawn any loss due to predation on the trip to the Pacific Ocean can be seen as major losses in returning salmonids to begin with. Avian predation from Caspian terns on Crescent Island and cormorants on Foundation Island, both located in the mid-Columbia River just below the confluence with the Snake River consume large numbers of salmonid juveniles yearly. Between 2004 and 2009 it was estimated that the annual take of juvenile salmonids by the tern colony on Crescent Island ranged from 470,000 to 800,000 and the Foundation Island cormorant colony consumption ranged from 333,000 to 500,000. As numbers of both species have increased in the last decade, it can be assumed that the take of salmonid juveniles has also increased. A well thought out solution needs to be addressed regarding what number of Caspian Terns and Cormorants are acceptable for the ecosystem as it exists today.	Through the Inland Avian Management Plan, the Crescent Island tern colony was eliminated by habitat management prior to the 2015 nesting season, with off setting habitat created in San Francisco Bay. Since 2015, there has been no tern nesting. However, a portion of the Crescent Island colony has moved to the Blalock Island complex. The Preferred Alternative includes a measure to disrupt this colony. The Preferred Alternative also includes avian deterrence at the lower Snake and Columbia River dams, and management actions at East Sand Islands for Caspian tern and double-crested cormorants. Other opportunities may exist to reduce the effects of colonial water birds on salmon and steelhead populations, but most would be outside the scope of this EIS and the authority of the co-lead agencies.
4802	2	j.comrada@comcast.net	N/A	Removing dams would have a positive effect on the general health of salmonids with regards to water temperature. The stagnant reservoirs behind the dams create dangerously hot water, and climate change is pushing the river over the edge. Year after year, the river gets hotter. The system is broken, but we can fix it, said Brett VandenHeuvel, with Columbia Riverkeeper, in a statement. As Brett VandenHeuvel suggests above, one of the most important limiting factors for cold water fish like salmonids is water temperature. And it can be problematic when a large body of water exists behind dams. The risk to salmon and trout populations associated with temperature is perceived to be high because: 1) the potential for biological effects exists according to laboratory-derived results; and, 2) many populations are already exposed to temperatures exceeding those believed to induce negative biological consequences. Water temperature plays a role in virtually every aspect of salmon life (Brett 1995; Weatherly and Gill 1995), and adverse levels of temperature can affect behavior (e.g. migration delays and timing), disease resistance, growth, and mortality (Brett 1956). From- AN ANALYSIS OF THE EFFECTS OF TEMPERATURE ON SALMONIDS OF THE PACIFIC NORTHWEST WITH IMPLICATIONS FOR SELECTING TEMPERATURE CRITERIA; December 2000 By Kathleen Sullivan of Sustainable Ecosystems Institute, Portland Oregon, Douglas J. Martin of Martin Environmental Seattle, Washington, Richard D. Carwell, Parametrix Inc., Kirkland, Washington, John E. Toll of Parametrix Inc., Kirkland, Washington, and the Weyerhaeuser Company, Tacoma, Washington	The EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives' effects on Snake River stocks, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Regarding water temperatures under dam breach scenarios, the EIS analysis of Multiple Objective alternative 3, which includes breaching the four lower Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action Alternative conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The models showed minor changes in the Columbia River under this alternative.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
4851	1	beachbum@nehalemtel.net	N/A	The Final EIS must include consideration of fish passage and reintroduction above Grand Coulee and Chief Joseph dams to support tribal fishery restoration goals in the Upper Columbia.	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, Federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the Columbia River System, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps.
4887	1	Madeleine Wiley	N/A	Incorrect EIS statements that say that congressional authorization is required to breach the dams. This is not true; our senators or Governor can demand that the dams be breached. Chapter 7.2 says:BEGIN QUOTE (slightly edited for brevity)The co-lead agencies determined that the No Action Alternative, as well as the following alternatives, MO1, MO2, and MO4 allow for the operation of the projects (meaning dams) in furtherance of all of the congressionally authorized purposes to varying degrees.Alternative MO3 would not meet the congressionally authorized purposes of operating and maintaining the four lower Snake River dams for navigation, hydropower, recreation, and irrigation.New congressional authority through new laws and associated funding would be required to implement dam breaching measures.END QUOTESo to summarize what I just read, the three agencies, do one thing. The build and maintain dams. That is their life. That is their congressional authorization (MAGIC WORDS). If you want to remove the dams, go get Congress to authorize that and get some money, because it will not happen with the local Corp of Engineers, or BPA, or Bureau of Reclamation.Thats their story, but it is totally wrong. Those magic words: congressional authorization are a smoke screen by the local lead agencies to make us believe that they cant take out the dams. In fact, they could do that very thing without additional congressional authorization.	If MO3 were selected as the Preferred Alternative, the Corps could use this EIS as a basis for seeking congressional authority to breach the four lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments.
4887	2	Madeleine Wiley	N/A	Who (from which organizations) evaluated the various options?Why did you (the lead agencies) not use a third-party organization such as Mitre to help evaluate the various options (alternatives) in order to generate an objective solution instead of keeping the decision "in-house". By not outsourcing the analysis you have put the agencies in the position of being totally biased regarding the "preferred alternative". I would think that this puts the lead organizations legally at risk.	The co-lead agencies used a multi-disciplinary and science based approach to analyze the alternatives in the EIS. The co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as cooperating agencies, and over 30 of those invited agreed to participate. Staff from the cooperating agencies joined the technical teams and provided their expertise and review to the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation and configuration of the dams in the Columbia River System and NEPA does not require a third party to evaluate the alternatives or to propose a specific solution, these are the responsibilities of the co-lead agency. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The draft EIS was subjected to two internal agency reviews by the Corps of Engineers experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. A list of the primary authors is included in Chapter 10.
4887	3	Madeleine Wiley	N/A	Did all organizations agree on the current draft EIS?Several sentences from the draft EIS make it appear that many organizations came together to work on this EIS. One such sentence is from the Preface:"More than 30 entities from across the region, consisting of tribes, Federal agencies, andstate and local governments, agreed to participate as cooperating agencies in thisNEPA process."However, another sentence from the draft EIS is quite troubling:" ..., the co-lead agencies identified a Preferred Alternative..."I could find no information that said that after the three co-lead government organizations picked "the final solution", that it was accepted and approved by each of the 30 entities that originally participated.Was there a vote, or other form of acceptance by each of the 30 organizations, or was the final alternative just decided by the three lead organizations. If the other organizations did not have a significant voice, then this EIS is flawed.	The co-lead agencies invited a number of entities (including tribes, states, and agencies) from across the region to participate in the EIS process as cooperating agencies, and over 30 of those invited agreed to participate. Staff from the cooperating agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation and configuration of the dams in the Columbia River System. Thus, the co-lead agencies identified the Preferred Alternative.
4887	4	Madeleine Wiley	N/A	Flawed methodology for evaluating alternatives. The EIS used only a subjective alternatives analysis. There was no weighting given to the eight Colombia River System Objectives. For each of the major alternatives, they were only subjectively scored on meeting, or not, the eight objectives. It is highly likely that if a different set of agency analysts worked on coming up with a Preferred Alternative, that there would be a different Preferred Alternative. Similarly, if another organization (like Mitre), were to audit this EIS, they would discover that the analysis of the alternatives would not be repeatable. It would be totally dependent onwhodid the evaluations, and not at all dependent ona weighted value of each of the major objectives. Therefore, the conclusion of this EIS, in creating the Preferred Alternative, is irrevocably flawed and the alternatives should be re-evaluated.	The co-lead agencies used a multi-disciplinary and science-based approach to analyze the alternatives in the EIS analysis. The co-lead agencies invited a number of entities, including Tribes, states, and local agencies, from across the region to participate in the EIS process as cooperating agencies, and more than 30 of those invited agreed to participate. Staff from the cooperating agencies joined the technical teams and provided their expertise and review to the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation and configuration of the dams in the Columbia River System and are not required to seek a third party reviewer for a NEPA document. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The draft EIS was subjected to two internal agency reviews by the Corps of Engineers experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets OMB circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by the Office of Management and Budget (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative meets the objectives of the EIS for ESA-listed juvenile and adult anadromous salmonids, resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
4964	1	N/A	N/A	Regardless of any hyped up representations of special interest groups or media our resource adequacy needs cannot be addressed by wind, solar, or energy storage technologies. In fact, as Washington's Clean Energy Transformation Act makes clear in its introductory language, Washington State's 100% clean energy goals would completely nonviable without the support of the federal hydro projects on the Columbia River.	The findings and discussion in Section 3.8, Air Quality and Greenhouse Gases, support the statement that hydropower is important for regional greenhouse gas emissions goals and future clean energy goals. Even with a renewable resource portfolio, the EIS finds that greenhouse gas emissions would increase under Multiple Objective alternative 3 and Multiple Objective alternative 4 consistent with the concern in the comment. Draft EIS, Section 3.8.3.5, pages 3-1009-1010.
4982	1	19timsorensen56@gmail.com	N/A	Additionally, I urge you to include in the final Record of Decision (ROD) strengthened and expanded measures to mitigate the predation of tens of millions of ESA-listed juvenile fish each year, particularly in the lower Columbia River, by various birds and predatory fish. I also hope the federal agencies will take full advantage of the provisions of the Endangered Salmon Predation Prevention Act to strengthen and expand protections for returning adult fish and I would like to see a strong commitment to do so reflected in the final ROD.	The Endangered Salmon Predation Prevention Act authorizes NOAA to issue permits to states and Tribes to kill sea lions in the lower Columbia River and some tributaries in order to protect certain fish from sea lion predation. The co-lead agencies do not have authorities to administer the Act. However, the co-lead agencies have supported actions to mitigate adverse effects to listed species from CRSO operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue as described in Chapter 7.
5001	2	Mike Petersen	The Lands Council	The DIES would have been more user friendly had all the data for the various options been put into each alternative. That is, all the mitigation, costs, etc. for each alternative put in one chapter instead of spreading it out in categories would have been easier to read. The public, if you sincerely want our input, needs to be able to see the alternatives holistically, and not flip from chapter to chapter to chapter.	The Final EIS will expand the table of contents that was in the draft EIS to assist readers in finding specific topics. The EIS also includes an index, so the public knows where to look for detailed analysis in either the main body of the EIS or the appendices.
5001	5	Mike Petersen	The Lands Council	California (and we dont sell that state nearly the amount of electricity we used to) is the most populous state in the nation. Yet that state, according to the Energy Information Agency, Jan. 16, 2020 update, says that is has the lowest per capita energy consumption level in the U.S except Hawaii. It does use a variety of energy forms, but nuclear capacity has declined and indeed there are fluctuations in the hydro generation there. But is has made extensive efforts to increase energy efficiency and implement alternative technologies that have slowed growth in energy demand. California has been proactive and creative. Here in the NW, the Federal agencies have not. Innovation is apparently too difficult to assess and is modeled on keeping the LSRDs in every way possible. Clean renewable energy forms dont get the press that they should. But a few clean energy projects are mentioned in the DEIS mitigation. Nor does battery storage improvement stories get mention. Lithium-ion batteries for example according to a Bloomberg NFF report, have fallen in price by 87% since 2010. Reading the Institute for Energy Economics and Financial Analysis would be very helpful in learning more about alternative and viable energy forms.	The comment compares clean energy development in California and the Pacific Northwest. Contrary to the comment, the EIS considered a variety of clean energy forms as well as energy storage. See draft EIS, Section 3.7.3.5, Potential Replacement Resources And Associated Costs at pages 3-904-909 and Table 3-162. The EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council (Council) in its 7th Power Plan (7th Power Plan, page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. See draft EIS, Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs at page 3-821 and Appendix H, Power and Transmission, Section 2.2. The EIS also examined the use of storage technologies considered a long-term resource of the Council's 7th Power Plan, but has become more commercially available since the release of the 7th Power Plan, and will likely now be considered a primary resource in the Councils 8th Power Plan. The comment suggests that additional energy efficiency should be assumed in the EIS, beyond what is achieved in the Councils Plan. The EIS analysis considers that all energy efficiency assumed in the Councils 7th Plan is appropriate and, likely, aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings from efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as in Multiple Objective Alternative 3. The EIS power analysis included all cost-effective conservation identified by the Council in the load forecasts analyzed in the power analysis (Section 3.7.3). All cost effective conservation in the region is assumed to be acquired consistent with existing law and mandates regardless of the status of the four lower Snake River dams. See draft EIS, Appendix H, Power and Transmission, Section 2.2 at H-2-3.
5001	9	Mike Petersen	The Lands Council	But, there is a better process. Congress should run it and write it and not the Federal agencies. It would be a full, honest stakeholder progress (including agencies) that acknowledges the prejudice of the dams and the Federal agencies who promote them. It would involve history, economics, biology, culture, politics and power that is seriously inclusive of more than just white wheat farmers and white people from Lewiston to the Tri-Cities. The main focus should be taking out the four LSRDs and then tweaking the subsidies for farmers and economics for recreation for the cities along the Snake. We could have a thriving economy for Snake River cities, farmers could still irrigate and get their wheat to market, our recreational fishers and ocean fishing vessels could still operate and make a living, and we could honor our Tribal treaties and have abundant fish and orcas if we are willing to be brave and honest and completely change our model. Its called collaboration and here are a few examples of how its been done in the Northwest. These two examples are diverse groups in a rural and urban setting. 1. The Northeast Washington Forest Coalition has worked with the Colville National Forest for 18 years and successfully restored nearly 100,000 acres of forest. In 2019, the Colville had the highest timber volume in the country, remarkable since it is one of the smaller national forests. 2. The Spokane River Regional Toxics Task Force has tackled reducing PCBs in the Spokane River. In doing so they are leading the way to find and mitigate this health problem and all without a court order. Setting up a collaborative process would bring all interested parties to the table to work out solutions to help salmon, farmers, fishermen, and utility users. We ask that you shift gears and try something new it works!	The dam breaching alternative, MO3 alternative, was considered and analyzed by the co-lead agencies in the Draft EIS. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Socioeconomic effects were analyzed in the Draft EIS. Any subsidies to economic sectors and investing in communities, including recreation, fishing, or towns, however, is outside the scope of this EIS and outside the authorities of the co-lead agencies. Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included "Protecting Native American treaty and reserved

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, Tribal perspectives, and economic vitality for the many people who depend on the Columbia River System for their way of life. The co-lead agencies will be active participants in regional discussions and solutions for mitigating the effects of the CRS and achieving broader recovery objectives.
5003	1	N/A	N/A	You could use this new EIS process to undertake **FUTURE** actions. Isn't it possible that BPA's financial situation will worsen with money lost on dams? Expensive spill and bypass systems do not seem to be working as well as the breaches would. Could you please have the federal agencies begin breaching *this year*? If you need more workers, surely there are so many out of work now that you could help the unemployed, dams, BPA, salmon, steelhead, and Orca and future generations.	The costs of breaching the four lower Snake River dams are described in Section 3.19.2 and in Appendix Q. MO3 would result in decreased costs or funding requirements for the four lower Snake River projects compared to the No Action Alternative, including capital costs, operations and maintenance, non-routine navigation, non-routine extraordinary costs, and fish and wildlife mitigation costs. However, breaching the four lower Snake River dams would also result in construction costs and costs for additional mitigation measures to address the adverse effects of MO3 consistent with information presented in Section 3.19. Based on the analysis of fish in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species. Moreover, the Corps does not have authority to breach the four lower Snake River dams. Consistent with the twin aims of NEPA, the agencies provided notice to the public in the Draft EIS of the Corps' existing authorities and the stepwise process that would be required if the co-lead agencies recommended MO3 as the Preferred Alternative. If this occurred, the Preferred Alternative would serve as a recommendation to Congress, which Congress would need to authorize. Congress would also need to authorize additional studies, including NEPA analysis, and funding for implementation. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets most other EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
5005	1	N/A	N/A	Air Quality: Farmers are taking care of this earth and are good stewards of the land, air and water. They depend on the rivers to get wheat to market. Barges move more wheat, use less fuel than trucks or rail cars. Adding more trucks and rail cars would add TONS of carbon to the Northwest skies. Per the 1992 OA/EIS (Appendix 4-59), there are air quality concerns relating to drawdown of reservoirsfugitive dust generated by strong winds blowing across exposed sediments during dry conditions (which can) result in high dust loadings and nuisance conditions for nearby residents and recreational users. There is a population of 60,000 people at the confluence of the Snake and Clearwater Rivers whose air quality will be significantly diminished until vegetation can be grown where acidic sand is revealed. The draft does not include adequate resources for revegetation and fails to take into account climatic conditions where re-revegation is to be done. Per 3-746, lines 22959 through 22963, it could take up to 10 years within dam breaching, to establish plan communities. Ten years is NOT an acceptable timeframe.	As described in this comment, the EIS evaluates the air quality and greenhouse gas emissions effects of modal shifts in shipping wheat from barges to road- and rail-based methods under MO3, finding up to a 53 percent increase in CO2 emissions (0.06 MMT CO2) relative to the No Action Alternative. The analysis additionally describes air pollution effects associated with increased potential for fugitive dust due to exposed riverbed along the Snake River. Multiple Objective alternative 3 was not identified as the Preferred Alternative and should alleviate concerns regarding revegetation that would have been implemented with that alternative.
5005	2	N/A	N/A	Cost: 3-1463, lines 9459 through 9466 discusses the loss of visitors costing the region 103 million, decrease in jobs and $39 million in labor income. The bulk of this impact is felt in a concentrated area. As a small community, these are significant losses that will have lasting effects.	The commenter is correct that in the short term during construction activities, a decrease of 2.3 million water- and land-based visitors in Region C could result in decreased visitor spending of $103 million, a decrease of 83 percent compared to non-local visitor spending under the No Action Alternative, as described in Section 3.11.3.5. Reduced visitor spending would result in a decrease of approximately 1,230 jobs, $39 million in labor income, and $147 million in sales during this construction period. After the construction and breaching period is over, access would be reopened to some of the recreation areas, and it is likely that a portion of the land-based visitors, such as sightseers, hikers, and others, would visit the region after construction while the reservoirs transition to river conditions. For comparison, all economic activity in Region C supports 216,800 jobs, $10.3 billion in labor income, and $31.4 billion in sales annually. As such, adverse effects under Multiple Objective alternative 3 would represent less than one percent of jobs, income, or sales in the region.
5005	3	N/A	N/A	Fish: Removing the Lower Snake River dams would have marginal salmon recovery benefits at significant cost to the region. Federal Data shows the dams in the system have world class fish passage facilities that see over 95% of salmon pass each of the dams on their journeys up and downriver. On January 7th 2020 Nez Perce Tribal Fisheries expert David Johnson stated that without hatchery fish, there would be no fishing. Recreational fishing does not allow to take of wild, endangered species of fish.	The co-lead agencies agree that salmon and steelhead are important resources of the Northwest and have invested significant time and resources at the projects covered by this EIS to improve survival and adult returns. The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service website at: https://www.nwfsc.noaa.gov/research/index.cfm.
5005	4	N/A	N/A	Recreation: The Columbia Snake River System supports water recreation and tourism, cruise ships, boating, fishing, jet skiing, paddle boarding, parks, public docks, camping, swimming, kayaking, and walking trails. Major loss of recreation would result if the four lower Snake River dams were breached. In FY2018, the U.S. Army Corp of Engineers counted over $1.7 million visits to the 26 area parks, boat ramps, beaches, and other recreational areas they manage within the Lower Granite Pool (see Attachment 1). Just one of those amenities. The Port of Clarkston has Cruise Boat traffic that generates over 25,000 passengers annually to the Lewis Clark Valley. Passenger surveys from cruise boats consistently identify with touring the deepest gorge in America as the very highlight of their week-long cruise in the Pacific Northwest. The Hells Canyon National Recreation area is only accessible by boat and increased visits in the past 10 years show increasing in numbers of visitors. In 2016, 6he Idaho Department of Parks and Recreation completed a study titled Economic Impact and Importance of Power Boating in Idaho (see Attachment 2). In this report, economists found spending in 2015 on power boating related products and services in Nez Perce County was over $14 million (p. 12). An additional $8.55 million was expended on other goods and services. This is a total impact of over $22.55 million. The draft EIS has vastly underestimated recreational impacts that would diminish or disappear altogether under MO3.	Cruise ship visitation is characterized in Section 3.10, including a description of its economic contribution to the region. Section 3.10.3.5 describes the contribution of cruise ships as supporting approximately 230 jobs in the region, $6.2 million in labor income, and $17.8 million in annual output (sales). Section 3.11.2.2 describes gaps in the recreational visitation data. Data are not available for all sites, including Hells Canyon National Recreation Area. The note under Table 3-256 in Section 3.11.2.2 in the Draft EIS states that visitation to National Forests and other USFS-managed lands is estimated for the entire unit, not specifically for recreation sites along rivers. The 2016 report by Boise State entitled Economic Impact and Importance of Power Boating in Idaho was considered for the EIS, but not relied upon directly due to the limited types of visitation data in the report. In addition, this region was not anticipated to be affected by changes in water surface elevations. However, additional information has been added to better describe fishing visitation in this region, its economic contribution to the communities along the Snake River and its tributaries, and the potential effects to fishing visitation under Multiple Objective alternative 3 in Section 3.11. Estimates of power boating use from that study are broadly consistent with visitation data from Federal and state agencies used in the EIS where data is available. The expenditure data collected for that study cover power boating in Idaho, while the recreational expenditure data applied in the EIS cover the Columbia River System basin and the broader range of activities reflected in the Federal and state visitation data.
5005	5	N/A	N/A	Energy and Navigation: The Columbia River System provides the Pacific Northwest with 90% of our renewable energy, supports tens of thousands of families, provides cultural and recreational opportunities, moves our food, raw materials and fuels. The Snake River provides power for our region and supports thousands of jobs. The Columbia River is the Trade corridor to the nation. Economists for PNWA, in the study at https://files.constantcontact.com/9a08bcf9001/8768ec34-9437-4adb-badb-477bde47019b.pdf, shows that the net present value of losses just for navigation is $1.9 billion. Lower Snake River dam breaching will likely increase the costs for farmers to get their wheat to market 50-100%. New carbon releases from truck and train movement of cargo will increase carbon emission by over 1.2 million tons per year (see PNWA study). The lower Snake River dams provide low-cost, carbon-free energy that cannot be replicated by other resources. The rural areas in the 10 counties most affected by an increase in rates are already at or below the federal poverty level, and dam breaching would affect the people and these communities that can least afford it. Our community, Clarkston, Lewiston, and Asotin would be devastated if dam breaching would occur.	The co-lead agencies did not include the measure to breach the four lower Snake River dams, which was evaluated in MO3, in the Preferred Alternative identified in the Draft EIS. As described in Section 3.10.3.5, Navigation and Transportation analysis for MO3, the EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are double, depending on their specific location and other conditions. The EIS evaluates the level of anticipated increases in truck and rail traffic that would occur under MO3. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent). The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. As described in the Section 3.8.3.5, Air Quality and Greenhouse Gas Emissions, for navigation and transportation emissions could increase from 17 percent to 53 percent depending upon how rail rates increase. The EIS findings regarding the importance of the four lower Snake River dams for the power system, low power costs and greenhouse gases are consistent with the statements in the comment. Regarding the specific power rate effects on certain counties cited by the comment, the EIS evaluated potential effects to power rates at a county level. See EIS, Section 3.7.3.5, Social and Economic Effects of Changes in Power and Transmission; see also Chapter 5 and Exhibit 1of Appendix H. Regarding the comment about the "most vulnerable communities" the Environmental Justice analysis in Section 3.18.3 provides further detail on potential disproportionate effects to tribal, low-income and minority populations.
5005	6	N/A	N/A	Visual: The once beautiful views of the reservoir will become a narrow stream. Per 3-747, lines 22976 through 22978, Approximately 3,000 acres of habitat management units that are currently irrigated under the No Action Alternative would no longer be irrigated and these lands would transition to upland plant communities. Brown barren acres will exist along the river where once the Clearwater Snake National Recreation Trail was green. It will remain this way for many years to come until it gets filled with noxious weeds and invasive plants. Per 3-749 23059 through 23061, long-term [vegetative] gains are based on the assumption that habitats will return to their pre-project distribution. It does not assume that habitat management units or Corps managed lands will be maintained. These conclusions are logical because surface water will not be accessible for irrigation. For one thing, there will be less of it. For another, a substantial amount of water is owed to the Nez Perce Tribe under the Snake River Basin Adjudication.	The visual impact analysis of MO3 finds that there would be a major effect from breaching the four lower Snake River dams. See Draft EIS pages 3-1286 to 3-1287. Mitigation has been identified. See Draft EIS lines 1096-1099 on page 5-35. With this mitigation, the major effect on visual quality would diminish over time as the shoreline revegetates and blends into the surrounding landscape. The co-lead agencies have added language to the visual section to expand this analysis. The measure to breach the four lower Snake River dams which was evaluated in MO3 was not included in the Preferred Alternative. The co-lead agencies are not aware of any factual basis to support the claim that "a substantial amount of water is owed to the Nez Perce Tribe under the Snake River Basin Adjudication." Rather, the co-lead agencies understand that the Tribe's water rights claims in the Adjudication were resolved in the Snake River Water Rights Act of 2004, Pub. L. 104-447. The effects of utilization of those water rights, as well as others in the Snake River Basin, are reflected in the hydrological modeling of flows incoming to the lower Snake River.
5005	7	N/A	N/A	Water supply: As mentioned above, there was a negotiation relating to water rights, and the Nez Perce Tribe received substantial entitlement. How has water supply been addressed in the DEIS given that entitlement? Other entities could not take on responsibility for green space along the Clearwater Snake National Recreation Trail, if they are not allowed to use surface water for parks and grassland that have been managed by the Corps under the Lower Granite project until now.	In Region C (lower Snake River), and potentially Region D (mainstem Columbia River) around the confluence of the lower Snake River, the MO3, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. The co-lead agencies understand that the Tribe's water rights claims in the Adjudication were resolved in the Snake River Water Rights Act of 2004, Pub. L. 104-447. The effects of utilization of those water rights, as well as others in the Snake River Basin, are reflected in the hydrological modeling of flows incoming to the lower Snake River. The EIS did not identify any effects to the Nez Perce Tribe water rights settlement.
5005	8	N/A	N/A	Indian Tribes: On P.24 of the Executive Summary, ongoing and disproportionate, social, cultural and socioeconomic effects to Indian Tribes and Tribal Communities is discussed. I would like to point out that since the Nez Perce Tribe began receiving rate payer money for hatchery and habitat programs, employment increases at the Tribe have grown exponentially. Natural Resource programs were a foundation for the Tribe that grew into creation of tribal casinos, the first Fiber-To-The-Home projectslocated on housing districts on the reservation--in North central Idaho, and most recently, the purchase of the Clarkston Golf and Country Club. While I may agree to a certain extent that something was lost culturally to the Tribes, no one can solely attribute loss solely as a result of river operations. Cultural losses began when others immigrated to historic Nez Perce grounds. Its due to the Federal Governments partnership with Tribes that they are better off than others non-Tribal residents of the Pacific Northwest. Returning the Lower Snake River to a riverine condition will not restore what has been lost by an infusion of the pop culture. MO3 will make very few properties of significance newly available because locations like Celilo Falls will not experience changes in any of the alternatives. Some cultural properties are actually protected because people cannot reach them. The Tribe can tell their story to obtain better understanding by other people today while Cruise Boat visitation occurs because historical and cultural information is supplied all along the tour, but when the dams go away this opportunity is lost.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Appendix P includes copies of tribal perspectives that were submitted by the tribes.
5007	1	mbk@joycekeefer.com	N/A	I have seen changes in marketing wheat after the dams went in. Selling our wheat was limited when we were farming in Montana. Now tremendous amounts of wheat are produced, not just in Montana but in Asotin and nearby Whitman County, which goes to feed the world. I believe that the Columbia/Snake River system is the largest wheat export gateway in the United States. Almost half of all wheat exports get to ocean-going vessel loading facilities on the coast by barges coming down the Snake and Columbia Rivers. Removal of lower Snake River Dams would stop that. Wheat prices per bushel today are not much different than they were in the 1960s and 1970s. Farmers would be out of business, because all their costs have gone up, if they hadnt worked with scientists to increase volumes per acre of production. Even so, wheat farming is subsistence living.	The EIS evaluates potential effects on farmers associated with increased transportation costs under Multiple Objective alternative 3 in Section 3.10.3.5. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted. The EIS recognizes that there is no guarantee wheat grown in the Northwest would be competitive now or in the future because there are many factors that influence international commodity markets (e.g., trade agreements, the U.S. dollar, global supply, etc.). However, the analysis finds that the cost to transport wheat to market would continue to be lower than costs paid by other wheat growers in the United States (e.g., the Dakotas and Midwest). Favorable conditions for Northwest wheat growers that help them stay competitive are: (1) the natural environment of the Palouse region (weather, soils) is ideal for growing this type of wheat, which leads to some of the highest yields per acre in the world, and (2) proximity of Northwest export ports. Currently, the cost to transport wheat to market is quite low relative to other parts of the United States and world.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
5014	1	caleb.j.merendino@gmail.com	N/A	Thus I must express my alarm at the way this comment period was conducted. The Draft EIS is a highly controversial and complicated document. The complexity of this issue, as well as the global emergency caused by the spread of the Corona Virus in the Pacific Northwest and across the country, calls for an extension of the comment period to provide adequate opportunity for feedback.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
5014	2	caleb.j.merendino@gmail.com	N/A	In addition to a lack of adequate response time, the mechanism used to collect comments through phone calls faced significant challenges, limiting participation in the public comment process, I do not feel that the public has been given adequate opportunity to make concerns fully heard.	The co-lead agencies are sorry you had difficulties. The public had several ways to submit comments such as the online comment form and through the mail. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public hearings in the region, the co-lead agencies determined the 45-day public comment period was adequate consistent with NEPA regulations.
5014	3	caleb.j.merendino@gmail.com	N/A	The DEIS recommendation of a Preferred Alternative essentially amounts to business as usual with minor modifications, and does not reflect the depth of the change needed to recover salmon populations and the species which depend on them. Experts agree that the past 25 years has shown that this approach is costly and ineffective, and a violation of federal law. The Draft EIS also fails to fully address the significant impact that the dams along these river systems have on the critically endangered Southern Resident Orca population. Accepted science indicates that restoring the lower Snake River would lead to stabilization of Chinook runs and provide critical food sources for the Southern Resident Orca.	There are many factors that effect salmonid populations, many of which are outside the control of the co-lead agencies. Both human-caused and natural factors that are outside the responsibility and control of the co-lead federal agencies, also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. While many measures have been included in the Preferred Alternative are from the No Action Alternative, most of these are measures that are know to provide benefits to ESA-listed species. These past actions by the co-lead agencies have resulted in a large percentage of fish being able to pass both upstream and downstream of the lower Snake River and lower Columbia River projects. See Section 3.5.2.3 titled Anadromous Fish. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Section 3.5 provides a summary of the fish analysis for the No Action Alternative and four of the multiple objective alternatives. Chapter 7 provides a summary of the fish analysis for the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NOAA and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The final EIS in Vegetation, Wetlands, Wildlife, and Floodplains (Section 3..6.2.6 and Table 3-102), and Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and the potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW. The co-lead agencies do not view the Preferred Alternative as a continuation of "business as usual." The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations. See Section 7.6.3 titled Preferred Alternative Operational Measures. In addition, a large number of structural changes are included to benefits salmonid species and Pacific lamprey. See Section 7.6.2 titled Preferred Alternative Structural Measures.
5014	4	caleb.j.merendino@gmail.com	N/A	Removal of the dams would also have economic benefits for recreation The Draft EIS does not address the positive impact that removing dams along the Snake and Columbia river would hold in terms of preserving our important natural resources as well as to boost tourism and the outdoor recreation economy.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region.
5014	5	caleb.j.merendino@gmail.com	N/A	A free flowing river is not only an essential for salmon recovery, but is necessary in order to right historical wrongs done to the Native American tribes of the Pacific Northwest region, who did not consent to the construction of these dams on their land, and whose important cultural sites including grave sites, were flooded by dam construction . The Palouse tribe was forcibly evacuated from the lands flooded by the Snake River dam construction, and continue to fight for recognition and return of their ancestral lands. In conclusion, a new approach is urgently needed to develop a comprehensive plan.	The CRSO EIS evaluated alternative plans for operation, maintenance and configuration of the system and identified the Preferred Alternative as the plan that best balances the multiple congressionally authorized project purposes and avoids, minimizes or offsets (to the extent possible) the associated environmental effects. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
5014	6	caleb.j.merendino@gmail.com	N/A	I strongly urge this body to extend the comment period to provide adequate opportunity for thorough feedback from the public and to restructure their Preferred Alternative proposal to reflect independent science around the urgency of dam impacts on salmon, tribal communities and Southern Resident Orca.	See response to Comment 5014-1.
5018	1	kanepat@hotmail.com	N/A	Many low lying areas on the lower river will be flooded during high run off if the dams are removed. Much of Portland and other cities will find themselves with flooding on a yearly basis like they did before the dams were built.	As described in Section 1.9.2.2 of the EIS, the four lower Snake River projects (Lower Granite, Little Goose, Lower Monumental and Ice Harbor) are run of river projects, and are not authorized for a flood risk management purpose. They were primarily developed for navigation or hydropower generation or both. Additionally, flood risk management analysis was completed for all CRSO EIS alternatives, evaluating flows and stages, both downstream of reservoirs and in reservoir pools, for each of the alternatives (No Action Alternative, Multiple Objective alternatives, and the Preferred Alternative). As described in summary of effects for Multiple Objective alternative 3 in Section 3.9.4.5, no change in flood risk is anticipated with the breaching of the four lower Snake River projects.
5021	1	N/A	N/A	I am also concerned about the impact the removal of the dams in this area would have on the water flow and supply systems.	Section 3.12.3.4 of the EIS describes that approximately 47,840 acres of land would be expected to go out of production with implementation of MO3. MO3 was not identified as the Preferred Alternative.
5022	1	N/A	N/A	Breaching the dams will negatively affect the amount of agricultural land we can utilize.	The Draft EIS analysis is consistent with this comment. Under Multiple Objective alternative 3 approximately 48,000 acres of land would no longer be irrigated.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
5024	1	monika.wieland@gmail.com	N/A	Since Columbia Basin salmon stocks were listed on the Endangered Species List in the 1990s, recovery plans have been in and out of courts multiple times, always failing to meet species recovery objectives. This time, it was specifically ordered to re-evaluate a dam breaching scenario, in light of the fact that previous plans continue to fall short on salmon recovery. It is time to do not only what is morally right, but what the law mandates, and that is to find a way to take the actions that are needed on behalf of salmon, and to deal with the difficult but surmountable consequences of that choice.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system Based on the EIS analysis the Preferred Alternative will make a substantial contribution to improving Snake River anadromous fish runs. With respect to the Preferred Alternative, the CSS model, which includes latent mortality effects, predicts that median Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
5024	2	monika.wieland@gmail.com	N/A	In addition to recovering endangered salmon, your report fails to take adequate consideration of the Southern Resident killer whales and their dependence on Columbia-Snake River fish. I was surprised to note the Southern Residents were not mentioned once in your 36- page executive summary, and only in passing in the report itself. The report states that Puget Sound is a more significant source of salmon for Southern Residents than the Columbia Basin, but thats just not true: the two largest salmon-producing river systems in the Southern Resident killer whale range are the Fraser River and the Columbia River. The Southern Residents only spend a fraction of their year in the Puget Sound region, a percentage of the year that has steadily declined over the last decade. The Southern Residents need abundant food sources year-round, including during the ample time they spend on the outer coast.	The Executive Summary is a high level summary of the CRSO EIS and is not intended to represent the importance of species and issues related to the CRS. SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5024	3	monika.wieland@gmail.com	N/A	NOAAs Southern Resident killer whale recovery plan states that perhaps the single greatest change in food availability for resident killer whales since the late 1800s has been the decline of salmon in the Columbia River basin. Their winter satellite tagging of Southern Residents further demonstrates the importance of Columbia River fish to K- and L-Pods in particular, with whales spending a significant portion of the late winter and early spring in the vicinity of the mouth of the Columbia River. Spring Chinook, including those that return to the Snake River, are of particular importance to the Southern Residents. It is irresponsible to downplay the importance of Columbia River fish and the impact of the Snake River dams on these endangered whales.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5025	1	eplucinak@gmail.com	N/A	And maybe more fish farms specifically to raise food for the orcas	The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by USFWS. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be minor. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production, including the mitigation hatcheries mentioned above, carried forward into the Preferred Alternative.
5026	1	hartsisk@frontier.com	N/A	Instead of spending millions on more studies and surveys about the dams, and billions on removing them, we would be better off spending that money on improving salmon habitat, installing better fish ladders, and cleaning up Puget Sound.	The co-lead agencies agree that salmon and steelhead are important resources of the Northwest and have invested significant time and resources at the projects covered by this EIS to improve survival and adult returns. The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service website at: https://www.nwfsc.noaa.gov/research/index.cfm. Actions in Puget Sound are outside the scope of this EIS, which focuses on Columbia River System operations, maintenance and configuration. The Corps is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
5031	1	N/A	N/A	Before any consideration is given to removal of the lower snake river dams there is a more easily reversible study that should be done. Open the Ballard locks and restore the riparian area of Lake Washington. If this results in a large increase in salmon it may be enough to support the Orca population. The Snake River dams are infinitely more costly to remove/bypass and even more costly to restore if the the salmon population did not return to desired levels. Loss of clean energy, efficient transportation and cruise ships/tourism would have a devastating impact on the inland northwest not to mention the ecosystems that have evolved around the slack water.	The CRSO EIS is intended to evaluate options for future operation and configuration of the 14 dams in the CRS. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. As such, the co-lead agencies analyzed effects of the alternatives on Southern Resident killer whale (SRKW), in particular how impacts to salmon and steelhead due to operations may influence prey availability for SRKW. Regarding the conditions of Ballard Locks and Lake Washington, those involve a variety of issues beyond the scope of this CRSO EIS. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Sections 3.4 and 7.8.3 of the EIS. Actions in Puget Sound are outside the scope of this EIS, which focuses on CRS operations, maintenance and configuration. Additionally, the US Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
5039	1	wiensthac@yahoo.com	N/A	First, I am deeply disappointment in the Draft EIS. Rather than embracing calls dating back to the 1990s for a major overhaul of hydrosystem operations to protect threatened and endangered salmon and steelhead, this new report recommends only minor adjustments to a status quo plan that will perpetuate many serious mistakes from the past. The draft report does not offer a new approach; rather it recommends minor tweaks to a 25-year federal approach that has cost billions of dollars, brought salmon and steelhead today to some of their lowest levels on record, helped push orcas to the edge of extinction, increased uncertainty for communities across the region, and has been invalidated five times consecutively in federal court. Flexible spill is the centerpiece of the governments Preferred Alternative. While the science shows that increased levels of spill can buy some additional time to put in place more effective actions for imperiled fish populations, it is not, by itself, a long-term survival strategy, let alone a recovery strategy. Indeed the parties to the current, short-term Flexible Spill Agreement made this explicit and respected regional scientists have confirmed that the flexible spill included in the Preferred Alternative will NOT deliver salmon the survival benefits through the hydrosystem they need. The changing climate will further erode any benefits of flexible spill as a long-term approach and only underscores the urgency for meaningful action.	The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The CSS model, which includes latent mortality effects, predicts that median Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. That result, however depends upon the latent mortality hypothesis central to the CSS model being correct. To address this uncertainty and minimize risk, the Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
5039	2	wiensthac@yahoo.com	N/A	Finally, a dramatically new approach is urgently needed to develop the comprehensive plan the people of the Northwest and nation require and deserve one that (1) recovers salmon abundance, (2) invests in fishing and farming communities to provide them a healthier future, and (3) supports a reliable, affordable and increasingly decarbonized regional energy system. Recovering salmon, protecting orca and meeting the needs of communities will require Northwest policymakers to actively support and work with stakeholders, sovereigns and citizens to build the package of investments and actions that can deliver the kind of comprehensive solutions we need. We can do this together. The conversations have begun, among farmers and fishers, conservation interests and utilities, and people from across the state and the region. This is the way forward. Our elected leaders must step up and lean in to help bring us all forward together.	The co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions and solutions for mitigating the effects of the CRS and achieving broader recovery objectives. The Preferred Alternative for long-term system operations, maintenance and configuration of the Columbia River System presented in the EIS is based on todays conditions and environment. Technology is quickly changing, as is the regions dynamic environment and energy market, and the region needs to consider new information and adaptively manage resources. The co-lead agencies recognize that no matter which alternative in the CRSO EIS is identified as the Preferred Alternative, the decision would likely draw criticism from some stakeholders or sovereigns. The region includes stakeholders, sovereigns, and other interested parties with diverse and varied opinions on these very important topics, and many are strong in the belief that their perspective is the best path forward. It is important to keep in mind that factors, both human-caused and natural, that are outside the responsibility and control of the co-lead agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the Columbia River System requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. The co-lead agencies look forward to participating in that discussion. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a substantial contribution towards recovery.
5041	1	N/A	N/A	The dams not only provide power and shipping possibilities (yes I know it is a corridor for shipping ~15B of goods annually), but upriver shipping is redundant - we have the means to compensate. The power output of the dams can be compensated for as well - the sedimentation of the dams is an inevitability and incurs further capital expenditure.	The EIS analyzed the effects on regional reliability if the four lower Snake River dams were breached in Multiple Objective alternative 3. To maintain regional power reliability at the No Action Alternative levels, additional replacement resources would be necessary. The EIS considered two resource portfolios to replace the power output of the lower Snake River dams: a least-cost conventional portfolio (natural gas) and a zero-carbon portfolio (primarily solar). See Section 3.7.3.5, pages 3-904-910 in the Draft EIS. Under both of these replacement portfolios, however, regional power rate pressure increases considerably. The rate impacts of these replacement resources, which includes cost savings from breaching the four lower Snake River dams, is described in Section 3.7.3.5, Table 3-166, pages 3-920-924 in the Draft EIS. As described in the EIS, even with the cost savings associated with reductions in dam operating and fish and wildlife mitigation costs, the net impact on power rates is in the range of between 13 to 50 percent (for zero carbon resources replacements) and 4 to 10 percent (for natural gas/least cost replacements).
5041	2	N/A	N/A	The economic benefit for fishing and recreation to the states of washington, oregon and Idaho are tremendous. Every year hundreds if not thousands of anglers make their trek to try their luck for this incredible resource that runs on our back yard. These people help prop up economies - no not like a big power corporation, but the small mom and pop fly shops, river shuttles, inns, restaurants, small rural towns. This is a resource that once lost cannot be brought back - we are quickly approaching the precipice of no return for what was once the greatest salmon run on earth.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which are described qualitatively.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. Broad-sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. However, fish analysis in Section 7.7.4 shows that the Preferred Alternative (PA) will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals. The CSS model predicts that the PA average Smolt-to-Adult return (SAR) rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the PA, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the PA includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants or Total Dissolved Gas-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS, for additional information.
5043	1	N/A	N/A	Topic 1 Regards the topic describe in this quote... "There is also the potential for additional major adverse effects to archaeological sites at Hungry Horse Reservoir due to the increased frequency and size of draw-downs to compensate for the removal of the Lower Snake River dams." (see Executive Summary p. 29) Western GeoArch Research conducted geoarchaeological investigations at 10 priority archaeological shoreline sites on Hungry Horse Reservoir in A.D. 2000. The investigation was oriented towards an evaluation of the site's National Register of Historic Places, criterion D, research potential. By and large these sites had been subject to decades of reservoir-induced, wave-swash that has eroded artifacts from their original behavioral-spatial spatial context. As a result of this erosion and displacemnt, the artifacts lacked archaeological stratigraphic provenience, spatial associations to one another, as well as lacked archaeological context. Archaeological data from these sites is unable to address any research question that relies on archaeological spatial integrity (see National Park Service 1990:49). REFERENCES CITED: Eckerle, William 2000 "Geoarchaeological Evaluation of 10 Priority Sites at Hungry Horse Reservoir, Flathead County, Montana, 2000-2001", Submitted to Flathead National Forest by Western GeoArch Research. Copies available from Western GeoArch Research, Driggs, ID. Lyman, R. Lee 2011 A Historical Sketch on the Concepts of Archaeological Association, Context, and Provenience. "Journal of Archaeology Method and Theory" 19:207-240. National Park Service 1990 "National Register Bulletin 15: How to Apply the National Register Criteria for Evaluation". Revised 1997. Washington D.C. CONTINUED...	In Section 3.16.1, the co-lead agencies state they choose to focus on assessing impacts to cultural resources regardless of whether or not the resource had been determined eligible for the National Register of Historic Places (NRHP). This allowed the co-lead agencies to consider the entire set of resources known to exist within the cultural resources study area and enabled the best comparative impact assessment across the system for every alternative considered. Over time, additional resources could be identified, or some resources may prove to not be eligible for the NRHP. Therefore, the co-lead agencies chose not to use eligibility as a requirement to include, or discount, a resource within the impact analysis. The total number of resources subject to impacts would likely change over time but for the purposes of this analysis, all resources were considered on an equal basis.
5043	2	N/A	N/A	TOPIC 2: Another topic, the United States' trust relationship with Indigenous Native American communities (United States v. Mitchell 1983) is discussed. The permitting and building of dams in the Columbia River Basin has greatly hampered the recovery of the fishery from early historic unregulated fishing (itself a breach in trust by the U.S.) as described in the following article in the Mountain Journal November 21, 2019. "Removing Lower Snake River Dams Is Best Chance For Salmon and Steelhead Recovery" https://mountainjournal.org/the-debate-over-saving-salmon-and-taking-down-dams By Helen Neville (Dr. Helen Neville, a senior scientist with Trout Unlimited) In his recent op-ed, Kurt Miller, the executive director of Northwest River Partners, an association of businesses that supports retention of the federal dams on the Columbia and Snake rivers, argued against removing the four lower Snake River dams to save gravely imperiled salmon and steelhead in the Snake River Basin. To support his case, Mr. Miller spliced together several pieces of information some accurate, some not that ultimately didnt support his conclusion. Mr. Miller argued historical commercial over-fishing was the primary culprit behind declines in the Columbia and Snake rivers. He was correct that unregulated commercial fishing caused severe declines in the late 1800s and early 1900s. But as agencies regulated harvest, stocks responded and remained relatively robust, even as the lower Columbia River dams were built. In fact, the precipitous declines in wild Snake River salmon directly mirrored the timing of the completion of the lower Snake River dams. Mr. Miller also noted that salmon and steelhead declines track recent ocean conditions. The ocean is an important driver of salmon abundance and has been for millions of years. Luckily, salmon and steelhead have developed remarkable life histories that lend resiliency in a highly dynamic freshwater and ocean environment until the last five decades, when Snake River stocks seemingly approached the limits of their resiliency (in contrast, stocks in tributaries below the Snake River dams have 2 to 4 times the adults returning from a given cohort of smolts, despite using the same ocean). After more than $16 billion invested to ameliorate the effects of the Columbia Basin hydro system on fish and wildlife, Snake River spring/summer chinook and steelhead are at record low abundances, and sockeye are barely hanging on. Climate change increases the urgency to restore passage. After more than $16 billion invested to ameliorate the effects of the Columbia Basin hydro system on fish and wildlife, Snake River spring/summer chinook and steelhead are at record low abundances, and sockeye are barely hanging on. Climate change increases the urgency to restore passage. How many fish do we need to achieve abundant, resilient, fishable levels? A diverse group of stakeholders from across the region, including Trout Unlimited and several members of Northwest River Partners Mr. Millers organization worked collaboratively over several years to come up with the answer. The group, known as the Columbia Basin Partnership, agreed that for spring/summer chinook salmon, 124,000 naturally reproducing adults in the Snake system would be an appropriate recovery goal. For steelhead, the recovery goal was set at 104,000 naturally reproducing adults. And according to the Columbia Basin Partnership, the Snake has, by a long shot, the greatest production potential for spring/summer chinook and steelhead. How do we meet these collaborative goals for wild, naturally producing Snake River spring/summer chinook and steelhead and sustain them through fluctuating ocean conditions and a warming climate? Mr. Miller says he supports science-based decision-making, so I ask him to join me in looking at the overwhelming scientific evidence that we need a free-flowing lower Snake River. Multiple collaborative, peer-reviewed, high-integrity scientific assessments that have included tribal, federal, university, consultant and state agency (including Idaho) scientists, have come to this conclusion. As a science-based organization, this is why we support removal of the lower Snake dams as the best way to give these fish a chance."	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. The EIS recognizes the economic and cultural importance of salmon to tribes in a number of sections throughout the document. Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Both human-caused and natural factors that are outside the responsibility and control of the co-lead agencies, also contribute to the decline and recovery of ESA-listed species, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the Columbia River System requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Based on the EIS analysis the Preferred Alternative will make a substantial contribution to improving Snake River anadromous fish runs. With respect to the Preferred Alternative, the CSS model, which includes latent mortality effects, predicts that median Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of the Northwest Power and Conservation Council's recovery target for the region) as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The commenters suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at Federal Columbia River Power System projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96 percent and 93 percent for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15 to 20 percent with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
5044	1	N/A	N/A	3. The DEIS overstates the cost of replacing power from the Snake River dams with clean energy	The EIS describes the replacement resources that would be needed to maintain regional reliability at the No Action Alternative (NAA) levels based on two replacement portfolios: one based on renewable resources and another based on natural gas resources, which are generally the least cost means to maintain reliability (Section 3.7.3.5 Potential Replacement Resources and Associated Costs in the Draft EIS). The EIS uses the best available resource cost information from the Northwest Power and Conservation Councils, Seventh Power Plan and Mid-term Assessment to estimate the potential range in costs of these replacement resources. The basis for developing both of these portfolios may be found in Section 3.7.3.1, Methodology, and Section 3.7.3.5 of the Draft EIS, Potential Replacement Resources and Associated Costs for Multiple Objective alternative 3 specifically. Based on responses to public comments, the Final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. See Chapter 3, Section 3.7.3.1.
5044	2	N/A	N/A	4. The DEIS ignores salmon and orca science: It dismisses the overwhelming scientific research that restoring the lower Snake River will provide salmon and steelhead with their best chance to recover, and it ignores the benefits of increasing those runs for critically endangered orcas and struggling fishing communities. 5. The DEIS fails to protect salmon: It fails to acknowledge that its recommendation for flexible spill at the federal dams will not deliver sufficient survival benefits for endangered salmon and steelhead.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The Draft EIS analysis found only a minor effect to the Southern Resident killer whale (SRKW) would result from implementing MO3, which includes a measure to breach the four lower Snake River dams. This conclusion is based on the fact that Chinook available to Southern Resident killer whales from the lower Snake River comprises only a small percentage of their overall diet. Changes to this portion of the SRKW food availability of the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but will not change their overall condition or population dynamics. The co-lead agencies note independent congressional authorizations will contribute to prey abundance for SRKW through the continued existence of authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service (USFWS). However under MO3, the co-lead agencies would no longer have an obligation to fund USFWS for the operations and maintenance of the Lower Snake River Comprehensive Plan facilities upon the breaching of the four lower Snake River dams due to the funding authority directly tied to the operation of the four lower Snake River dams. Additional details on the most crucial prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The CSS model, which includes latent mortality effects, predicts that median Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. That result, however depends upon the latent mortality hypothesis central to the CSS model being correct. To address this uncertainty and minimize risk, the Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
5044	3	N/A	N/A	6. The DEIS ignores the benefits and opportunities of salmon recovery for communities: The DEIS focuses on the financial costs of salmon recovery and ignores the enormous sacrifices already made by Tribes and rural communities in terms of lost fishing opportunity, reduced jobs and incomes, impacts on Tribal cultures and diets, and other socio-economic effects.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. In particular, the cultural significance and impacts of salmon and steelhead fisheries are described in the Fisheries section 3.15.2.1, which includes sections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries.
5044	4	N/A	N/A	11. Unfortunately, despite the DEIS' recognition that restoring the lower Snake River would deliver the greatest survival benefits to Snake River fish compared to any of the other options, it instead recommends a Preferred Alternative with only minor modifications to a longstanding approach that has proven to be illegal, costly and ineffective over 25 years. 12. As stated in Chapter 2 of the Comparative Survival Study (CSS) Annual Report for 2019, "Among the federal alternatives, MO3 (the four dam breach alternative) resulted in the highest SARs (Smolt to Adult Return) and in-river survivals In light of looming salmon and steelhead extinctions, MO3 (4-dam breach) must be implemented. Nothing less will enable fish survival. 13. The draft report does not offer a new approach; rather it recommends minor tweaks to a 25-year federal approach that has cost billions of dollars, brought salmon and steelhead today to some of their lowest levels on record, helped push orcas to the edge of extinction, and has been invalidated five times consecutively in federal court.	The co-lead agencies used high quality information in the EIS analysis. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and would average well above 2 percent (the lower end of the Northwest Power and Conservation Council's recovery targets for the region), increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia River Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
5048	1	N/A	N/A	Removing the dams would remove over 48000 acres of land from being irrigated and greatly impact agriculture and needed agriculture.	This comment is consistent with the analysis in Section 3.12 of the EIS.
5049	1	younksky@gmail.com	N/A	Please, PLEASE consider that while the intent to protect native fish populations is good, other measures (such as dam improvements like spillways and increased spilling in the spring) MUST be taken instead, thus preserving the integrity of our beloved dam system.	The co-lead agencies evaluated numerous measures intended to benefit resident and anadromous fish, including spill, improvements to fish ladders, and improved fish passage turbines. The Preferred Alternative includes many measures to improve conditions for fish at the dams and spill for juvenile fish.
5050	1	beyer.aarohn2015@gmail.com	N/A	Sending barges to lewiston Idaho was never a good idea and it did not live up to expectation that the government had promised such as economic activity that it would supposedly bring in. We would need a different approach in exporting our crops if the dams do get taken out. Rail, the answer is rail! Our country was built by the railways and its time to go back to that method. Look at the data, AKA the feasible studies they have done and they state they are no longer feasible.	The EIS evaluates the impacts of the loss of barge services in the lower Snake River under MO3 and finds that costs to farmers would increase if barge transit is not possible. Transit of all shipments would be feasible at an increased cost via truck and rail, and increased air emissions would result. MO3 was not identified as the Preferred Alternative in the Draft EIS.
5050	2	beyer.aarohn2015@gmail.com	N/A	Our electrical grid can afford to lose 12% energy being produced. Which is what all 4 of them can produce. Yes lower granite does have turbines that can produce more than dworshalk alone but since they are a "run of a river type dam" they can NEVER take full advantage of the turbines in the 4 dams.	Though it does not happen routinely, there are times when all of the six turbines at dams on the lower Snake River may run at the same time. Contrary to the statement in the comment, however, the EIS finds that the loss of the hydropower generation under Multiple Objective alternative 3, which includes the measure to breach the four lower Snake River dams, has adverse effects on regional power reliability, increasing the likelihood of power shortages unless and until replacement resources are acquired. See Draft EIS, Section 3.7.3.5, Effects on Power System Reliability, page 3-903; and Appendix H, Table 2-1. While the four lower Snake River dams are indeed run-of-river projects, upstream storage projects (Dworshak and Brownlee), regulate some of the water flowing into the lower Snake River, which flows year-round. In particular, the lower Snake River projects produce a substantial amount of power in the winter, which is currently the region's highest demand period. The comment suggests that the region is energy surplus. This surplus is an average figure, which assumes average conditions. While the regional power system does have surplus on average and in some periods, most typically in the spring of high-water years, there are also periods when the region has very little or no surplus. For example during a winter cold snap, demand for power may reach its annual peak. During a heat wave in summer when demand for power is high, river flows may be relatively low and several Federal and non-Federal hydropower projects are spilling water for juvenile fish passage. The EIS analysis for Multiple Objective alternative 3 indicated that there is roughly a 14% chance of energy shortages in any given year (without factoring in the retirement of additional coal plants). See Section 3.7.3.5 of the Draft EIS, Table 3-165. Appendix J, Chapter 4 shows the seasonal variation of the loss-of-load events.
5050	3	beyer.aarohn2015@gmail.com	N/A	They are useful for only 1 reason and that is barges. Now if you look to see how much it costs each year to keep the locks and dams maintained every year and also add up the dredging of the river channel the total cost exceeds what we get back in the economy from the barges. Plain and simple. Add in the millions of dollars the BPA has spent on salmon and steelhead which is obviously not working as well. You want results that work? Tear the dams out. Take the Elwa dam removal for example. It will cost less money to removed the dams than it will be to maintain them for the next 50 years. People that are educated on the matter all know that they are in need of major repairs that cost millions of dollars.	The EIS evaluated the tradeoffs associated with the management of the system, which has multiple objectives. It was not an analysis that aimed to compare the benefits of navigation against the costs to salmon. The EIS estimates the costs to operate the Columbia River System dams, as well as the costs to the navigation and transportation industry that would occur if the four lower Snake River dams are breached under Multiple Objective alternative 3 as part of this analysis that aims to balance the objectives for the system.
5055	1	epfuerst@frontier.com	N/A	One is that impact on Southern Resident Orcas is not even mentioned.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects.
5055	2	epfuerst@frontier.com	N/A	Another is that there is absolutely no consideration of the huge impact of failing salmon and steelhead returns on sports fishing businesses and communities in Idaho and Washington was not a factor.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
5055	3	epfuerst@frontier.com	N/A	Lastly, I believe that to make no adjustments to the 45 day limit for comments on an 8,000 page document, while the coronavirus has changed everything in our lives, makes me wonder if you take this feedback seriously, or if you have already made up your collective minds.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
5055	5	epfuerst@frontier.com	N/A	III. The DEIS overstates the cost of replacing power from the Snake River dams with clean energy.	The EIS relies on the resource cost analysis provided by the Northwest Power and Conservation Council in their 7th Power Plan and the Mid-term Update. See Section 3.7.3.1, Step 3: Determine Need for Potential Replacement Resources and Associated Costs, at 3-821 and Appendix H, Power and Transmission, at Section 2.2 in the draft EIS. The EIS analysis used the Councils GENESYS model to assess the reliability of each of the alternatives, including Multiple Objective (MO) Alternative 3. While MO3 includes other measures besides breaching the four lower Snake River dams, the majority of the power impact is due to the loss in generation from the four dams. There are a number of uncertain factors in the cost of replacing the power in MO3, discussed in Section 3.7.3.5, in particular in Electricity Rate Pressure, and highlighted in the rate sensitivity analysis, (see Table 3-166 in the draft EIS). To address concerns about potential reductions in resource costs, publicly released draft information, such as updated prices for solar and battery storage, from development of the 8th Power Plan is included as rate sensitivities in the Final EIS. The Final EIS will include the de-escalating cost curves prepared by the National Renewable Energy Laboratory (NREL) that will be used by the Council in the 8th Power Plan.
5055	6	epfuerst@frontier.com	N/A	IV. The DEIS ignores salmon and orca science: It dismisses the overwhelming scientific research that restoring the lower Snake River will provide salmon and steelhead with their best chance to recover, and it ignores the benefits of increasing those runs for critically endangered orcas and struggling fishing communities. V. The DEIS fails to protect salmon: It fails to acknowledge that its recommendation for flexible spill at the federal dams will not deliver sufficient survival benefits for endangered salmon and steelhead. VI. The DEIS ignores the benefits and opportunities of salmon recovery for communities: The DEIS focuses on the financial costs of salmon recovery and ignores the enormous sacrifices already made by Tribes and rural communities in terms of lost fishing opportunity, reduced jobs and incomes, impacts on Tribal cultures and diets, and other socio-economic effects.	Based on our analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. In compliance with ESA, the co-lead agencies submitted Biological Assessments to NMFS and USFWS (Appendix V). In this Final EIS, the Biological Opinions from NMFS and USFWS can be found in Appendix V, completing ESA consultation on the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return (SAR) rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. In Section 7.7.8, the co-lead agencies conclude that impacts from the Preferred Alternative on Southern Resident killer whales would be minor. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. The Draft EIS provides extensive analysis of the impacts of the Preferred Alternative in comparison to the No Action Alternative to Tribes and rural communities cited by the commenter in Section 7.7.17, 7.7.19, and 7.7.20, while socioeconomic effects are discussed throughout Chapter 7 and summarized in Table 7-45.
5057	1	dcll1960@gmail.com	N/A	Secondly, I find a great miscarriage to the Clearwater communities and other communities the rely on economic benefit from sport fishing that those benefits were completely ignored in the draft EIS. There are numerous economic studies that have evaluated economic contributions of outdoor recreation and sport fishing within this system. Including economic benefit from irrigation, navigation and hydropower, yet leaving out sport fishing and associated recreation is completely unacceptable and ignores the devastating economic impacts the declining salmon and steelhead population populations have on these communities.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
5082	1	Opal R.	N/A	Please supplet[sic] the 2002 Environmental Impact Statement Immediately and use alternative #4 to breach the Lower Four Snake River Dams in 2019.	The EIS acknowledges previous analyses conducted in the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement. However, the EIS relies on the high quality information to evaluate the tradeoffs associated with breaching the four lower Snake River dams under MO3. The EIS acknowledges previous analyses of breaching the four lower Snake River dams, such as the 2002 Lower Snake River Juvenile Salmon Migration Feasibility Report and Environmental Impact Statement analysis referenced in this comment. However, the EIS relies on current information to evaluate the tradeoffs associated with dam breach under MO3. This includes applying current models and data rather than relying on findings from studies conducted nearly 20 years ago. Thus, the agencies chose to prepare a new EIS focused more broadly on Columbia River System operations, maintenance and configuration, using updated information.
5084	1	N/A	N/A	See attached Comment Letter.	Unfortunately, an attachment was not received from the commenter. The commenter did not provide any contact information the co-lead agencies could use to request these comments, so a response was not provided.
5089	1	christy1125@msn.com	N/A	However, the most immediate and significant affect will surely be that of increased electrical costs. It is projected that the current plan, endorsed by the salmon advocates (removing dams on the Snake River), will raise the cost of electricity by 50% wholesale and 25% retail. The EIS reports these estimated increases to be "reasonable". It is suggested that more natural gas production and usage can offset any of these negative impacts. The impact on blackouts also dramatically increases - which is devastating for those using medical equipment needing electricity. The majority of those being impacted by breaching these dams will be in the state of Washington. However, little note is made to surrounding states that also depend on either the purchase of water or electricity from these rivers. I live in the Teton Valley in the far eastern edge of Idaho and I believe that the economic effects will be dramatic for me and my neighbors. There is no natural gas energy available in all of our valley. There is some propane available, however the vast majority of residents are completely dependent upon electricity for all of their energy needs. We have an electric cooperative here which has managed to keep our costs fairly stable, however still on the high side compared to communities that have more energy competition.	The comment that replacing the four lower Snake River dams under Multiple Objective alternative 3 would drive up costs in the region is consistent with EIS findings. See Draft EIS, Section 3.7.3.5, Table 3-166. The comment that breaching the four lower Snake River dams would increase the frequency of power shortages unless and until replacement resources were built is also consistent with EIS findings. See Draft EIS, Section 3.7.3.5, Effects on Power System Reliability, page 3-903; and Appendix H, Table 2-1. The EIS power analysis considers Teton Valley and all of Idaho in the analysis of potential power effects. The Environmental Justice analysis in Section 3.18.3 provides further detail on potential disproportionate effects to tribal, low-income and minority populations. Chapter 5 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers.
5094	1	paul@Presari.com	N/A	It is really difficult to read the summary and understand the difference between the Alternatives. There is no easy way to even compare and contract the alternatives against the Preferred Alternative. So I find the Summary to be inadequate in that it fails to communicate and distinguish the alternatives from each other in a meaning, logical and concise manner. There is not even one table or graphic which seeks to describe the key proposals and use illustrations to define and depict the differences so that anyone can grasp the significance of the major factors in play. This deficiency renders the process useless for sound decision-making.	The Draft EIS includes analysis of five Multiple Objective alternatives (MOs) and a No Action Alternative (NAA). The Executive Summary provides an overview of the much longer Draft EIS, which contains highly detailed analysis and results. The Executive Summary also provides an overview of the major environmental effects of the Preferred Alternative, but it is not intended to be a substitute for the CRSO EIS document, which includes in Chapter 7, a comprehensive and detailed description of the environmental effects and mitigation for the Preferred Alternative. Table 2-12 on page 2-75 of the Draft EIS lists the measures that are in each of the MOs and the NAA and Table 7-2 lists the measures that were carried forward, modified, or added to the Preferred Alternative. The Final EIS includes a comparison among the No Action Alternative and the five MOs, including the Preferred Alternative.
5103	1	N/A	N/A	Truth be known the seals and sea lions in the Columbia River as far inland as Bonneville Dam harvest an undocumented number of salmon. A protected species (Seals and Sea Lions) in an area that they are not indigenous to is a complete denial of the real problem.	Sea lions are protected under the Marine Mammal Protection Act and are an indigenous species to the Columbia River. The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including reduction of pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
5106	1	chipd30@comcast.net	N/A	The biggest stress on the CRS is overpopulation. If that is not addressed, anything done regarding dams will at best only have a minor temporary effect. Commercial fishing off the coast sucks up fish 24 hours a day to feed our population. Anyone that's driven up the Columbia Gorge can't help but notice the numerous floats with nets attached. Between the commercial fishing, recreational fishing and Indian fishing, it amazes me that any fish make it to spawn. The Indians have adapted and they sell their fish year around at many places along the river. This hurts their claim of loss. The dams on the lower Salmon River have the lowest fish casualty rates of dams in the world. Their removal will not bring the desired change in fish populations.	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those the commenter mentions. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service website at: https://www.nwfsc.noaa.gov/research/index.cfm. Harvest certainly has an impact on salmon and steelhead populations. The co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and.
5106	2	chipd30@comcast.net	N/A	Climate change is reducing water flows in many rivers in the US. That will mean less water for all that depend on it. Taking out dams will not reduce the impact of climate change on water flows and availability.	Climate change is more complex than stating that water flows in the United States are being reduced. In the Northwest, many of the climate projections indicate increased winter and spring runoff and decreased summer and fall flows. Please see Chapters 4 and 7 for more information.
5113	1	hall.sue60@me.com	N/A	I understand these dams were built in the 60's & 70's to generate hydroelectricity for the Northwest & provide transportation of goods by barges. The Northwest can now replace the energy produced by these dams many times through wind & solar energy. The energy produced by these dams is now surplus & no longer needed. The use of barges for transportion of goods has dwindled more than 70% & is no longer cost effective. Grain is apparently the main product shipped by barge & is occurring only because it is subsidized by the federal government. However the cost of the operation of the locks & dredging every 3 to 5 years is prohibitive. Then there is still the exorbitant cost of maintaining the dams that are 50 to 60 years old which will no doubt increase as time goes by. By removing these dams the 140 miles of Snake River & the salmon population will be restored. It has happened in the removal of other dams.	While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. As explained in Section 3.7.3.5 of the Draft EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are among the most valuable projects in the FCRPS. Breaching the four lower Snake River dams would have a direct and substantial impact on the supply of Federal power and require replacement resources (either natural gas or renewables), placing upward pressure on power rates. Contrary to the statement in the comment, the EIS finds that the loss of the hydropower generation under MO3, which includes breaching of the four lower Snake River dams, has adverse effects on regional power reliability, increasing the likelihood of power shortages. See Draft EIS, Section 3.7.3.5, Effects on Power System Reliability, page 3-903; and Appendix H, Table 2-1. The four lower Snake River dams are cost effective. Hydropower benefits exceed costs by $209M to $513M annually. The average annual costs to operate and maintain the four lower Snake River projects is $75M (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32M (Appendix Q, Table 4-1). The annual hydropower (Table 3-171, Draft EIS) and navigation (Table 3-244 and Table 3-246, Draft EIS) benefits alone for these projects are estimated at $284M to $588M in the base case analysis for MO3. These hydropower values include the effect of other measures in MO3, but the majority of this value stems from generation at the four lower Snake River dams. This estimate is derived from what the hydropower analysis called the base case and does not account for the full characteristics of the lower Snake River projects generation such as sustained peaking capability and fast ramping ability to integrate variable renewable energy sources. Fully replacing the generation capabilities of the four lower Snake River dams could roughly double estimated replacement resource costs as described in Section 3.7.3.5. It is true that barge movements on the Snake/Columbia river have declined somewhat over the past 20 years, but not by 70 percent. While it is true that the Snake River freight volume is certainly smaller than the volume of the Mississippi and Ohio River systems, it is nonetheless an important transportation option for a large volume of freight, particularly for farm products, with the Columbia-Snake River system serving as one of the largest exporters of farm products in the U.S., and the largest exporter of wheat. The co-lead agencies' analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short-term. These effects are considered in the context of the overall objectives of the EIS.
5127	1	flint.stephan@gmail.com	N/A	There will be ample time to pursue an array of improvements to accommodate the intermittent nature of renewable energy that will replace the lost power: Expansion and increased connectivity of the power grid. [Aside from a discussion of a Tri-Cities to Ice Harbor link, and mention of grid congestion, there seemed to be no discussion on increased connectivity to distant resources. Isnt this typically used to accommodate the intermittent nature of renewable energy?] Demand-side reduction [lots of potential here new products like heat-pump water heaters keep showing up on the market, as do induction cooktops, small heat pump units replacing resistance heating, etc; time-of-day metering may also play a role now that we all have smart meters and appliances with programmable operating times]. Pumped storage [I could not find any entries under pumped storage in the index! This has been done for years at Banks Lake, yet this is not in the index either! There is one paragraph in Ch 3 that assumes (and dismisses) one huge pumped storage facility, rather than integrating it as a smaller part of a larger plan.] Dispersed generation [The document assumes renewable generation would consume large amounts of land, but an aggressive campaign for options like net-metered rooftop solar could decrease this and be implemented quickly without the lengthy permitting process needed for large facilities.]	The comments that the EIS modeled transmission system congestion as well as power flows and identified a concern in the Tri-Cities area are correct. The EIS analysis considers the role of imports and exports of power; however, additional new transmission interconnections were not considered a viable way to replace lost power. The commenter describes multiple technologies, both emerging and currently available, that may serve as potential replacement resources for lost hydropower. The EIS acknowledges that technological improvements would likely bring other options; many of the concepts suggested by the commenter could feasibly provide benefit, but are currently not available in quantities sufficient to maintain regional reliability as described in the EIS. The energy sector is constantly undergoing transformation. With new technologies and practices being introduced all the time, the analysis in the EIS is unable to capture all potential permutations of resources. The EIS examined all potential resources identified in the Northwest Power and Conservation Council's Seventh Power Plan and Mid-term Assessment, relying on these sources for resource information. The commenter specifically raised three areas of note: expansion and interconnectivity of the power grid, demand side reduction, and pumped storage. With respect to expansion and increased interconnection of the electric grid, the EIS concentrated on a minimal set of transmission infrastructure to replace the resources (speaking specifically to renewable resources for this comment). While additional transmission could be developed to incorporate more remote resources, those transmission additions would bring additional costs. Rather, the EIS considered wind and solar resources that were in promising areas for wind and solar resources as well as closer to existing infrastructure to take advantage of the latent capacity on the system without the added cost of integrating more remote resources. The EIS in the carbon free portfolios included the Northwest Power and Conservation Council's Seventh Power Plan 600 MW target for demand response and all cost effective conservation in the load forecast, which did not include pump storage as among these resources. Nevertheless, the EIS did evaluate pumped storage as a potential replacement resource among other storage technologies. See Draft EIS, Section 3.7.3.5, page 3-909. While there are several feasible sites in the region that could provide pumped storage capacity, those projects have additional cost, permitting and environmental concerns. There is also uncertainty that these resources would provide sufficient energy and capacity to provide a credible source of replacement resources; the capability of pumped storage would not be able to address the scope considered in the EIS. See Draft EIS, Section 3.7.3.5, page 3-909. Appendix H (Chapter 2) provides additional details on resource selection, including discussion of pumped storage.
5130	1	N/A	N/A	Dam breaching (MO3) gives salmon the best chance of recovery of the alternatives presented in the DEIS. The DEIS should consider another option to breach the four lower Snake River dams and utilize spill at the Columbia River dams to 125% TDG. This results in the best scenario for salmon recovery. This management option is outlined in detail as the MO34 alternative proposed by the Fish Passage Center in Chapter 2 of their Comparative Survival Study 2019 report. NOAAs own recovery plan states, [p]erhaps the single greatest change in food availability for resident killer whales since the late 1800s has been the decline of salmon in the Columbia River basin. The DEIS underrepresents the importance of Columbia basin salmon in the diet and fitness of Southern Resident killer whales. In fact, they are not mentioned once in the 36- page executive summary.	The Preferred Alternative includes fish passage spill that is similar to the spill analyzed in Multiple Objective alternative 4 (MO4). The Preferred Alternative is described in Chapter 7, including a description of the measures being used and the rationale for why other alternatives, including MO3 and MO4, were not selected as the Preferred Alternative. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. Two of those objectives are directed at salmon and steelhead. Additionally, the CRSO EIS evaluated spill at ranges from 125 percent to 110 percent Total Dissolved Gas (TDG) across the alternatives including under MO3, which includes the measure to breach the four lower Snake River dams, where 120 percent TDG spill was evaluated at the four lower Columbia River dams. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3, which includes breaching the four lower Snake River

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. MO4 also had significant regional economic impacts, specifically to power. The proposed combination of MO3 and MO4 would likely satisfy fewer EIS objectives to lesser degrees. For power and transmission, for example, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about 1 in 7 years. MO4 would produce power shortages in about 1 in every 4 years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5 percent of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River dams, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125 percent and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
5130	2	N/A	N/A	In the full DEIS, all of the alternatives were predicted to have a negligible effect on Southern Resident killer whales with the exception of MO3 (dam breaching) which predicted a minor effect.	The Preferred Alternative is anticipated to have negligible effects to SRKW (see Section 7.7.8), while MO3 is anticipated to have a minor effect (see Section 3.6 of the FEIS).
5130	3	N/A	N/A	The report also states that Puget Sound Chinook salmon stocks are more important than Snake River stocks due to their availability for greater periods of time during the year but fails to recognize the biological need of Southern Resident killer whales to have continuous access to salmon from a variety of river systems. The orcas cannot depend on 2-3 river systems or seasonal periods of abundance to provide adequate prey resources all year. Southern Resident killer whales spend over half of the year in coastal waters. Columbia basin salmon comprise over half of their outer coast diet. Spring Chinook are of particular importance for Southern Resident killer whales.	The quantity and quality of prey is one of the limiting factors identified by the National Marine Fisheries Service (NMFS) in recovery of Southern Resident killer whales (SRKW), along with vessel traffic and noise, toxic contaminants, and other health risks (e.g., inbreeding). The operation of the CRS directly affects Chinook salmon, both wild, natural and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKW. However, according to NMFS, in terms of abundance of salmon available to SRKW for prey, populations of some Snake River adults stocks are now greater than they were in the 1960s, before the four lower Snake River dams were built. NMFS scientists maintain that recovering salmon stocks for SRKW goes beyond the Columbia River Basin, and that hatcheries produce more than enough Chinook salmon in the Columbia River Basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW. Additional details on the most crucial prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613 The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The Preferred Alternative (PA) carries forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The PA has negligible effects on SRKW as described in Section 7.7.8 in large part because hatchery production is consistent between the No Action Alternative and the PA. Again, this conclusion is based on the fact that Chinook salmon available to SRKW from the lower Snake River comprises only a small percentage of their overall diet. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent, congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation, and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by the U.S. Fish and Wildlife Service (USFWS).
5146	1	N/A	N/A	Surely we can design passage ways for fish to cross each dam in both directions and still generate electricity and barge transport. Screens above the dam could direct fingerling toward sloped ladders, these same passages should allow adult fish cross the dams. Screens would be swinging gates that open to allow barges to pass.	Over the last 20 years researchers, scientists and biologists have worked to improve survival and passage of salmon and steelhead at dams and projects in the Columbia River Basin. For this EIS, alternatives were developed from actions identified in public scoping and in meetings with regional scientists and biologists. New fish passage structures and improvements to existing structures were discussed and some were included in the current alternatives. Other measures were removed from consideration because they were not technically feasible.
5162	1	N/A	N/A	In reading the DEIS, I tried to develop a data-driven viewpoint by extracting numbers for both direct and indirect costs of removing the dams and also for the effect that removing the dams would have on the survival of salmon and steelhead. Not only what the total costs would be for physically removing the dams, but also for replacing the lost hydropower and peaking power, barge transportation and irrigation. I looked for an assessment of indirect costs to consumers such as the increased expenses to retail ratepayers, the added prices of food products, and increased fuel costs. I also scoured the Executive Summary and the report appendices for meaningful numbers for predicted fish restoration based on the models used. This buried information was nearly impossible to assess, but here's what I learned or inferred: Direct costs of removing the dams would run about 2 billion $ for breaching. Replacing lost hydropower with greenhouse-gas-producing coal/gas fired plants and developing the presently lacking battery storage technology needed to provide steady power from wind or solar generation would cost unknown billions of $ more. Less tangible costs would come from assuring vital peaking power to avoid brownouts when the other sources are not available. Indirect costs would include an estimated 50% rate increase for retail users. More useful numbers may be in the report, but are hard to find. Assessments given in the main report sections were qualitative rather than quantitative, i.e., more fish etc. Against the high costs of dam removal is balanced the projected increases in salmon and steelhead populations.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. The EIS does not employ a cost-benefit framework for decision-making. Consistent with NEPA analysis framework, the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. Consequently, a focus solely on the monetized economic costs and benefits would exclude important tradeoffs associated with the alternatives communicated in the EIS, including effects on fish. The EIS evaluates the performance of the CRSO EIS alternatives against the Purpose and Need Statement and EIS objectives, for example improving fish passage and survival, providing for reliable power generation, and minimizing greenhouse gas emissions. Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives.
5162	2	N/A	N/A	However, the projected long-term increases in fish populations based on models described in the DEIS are not large. For example, the predicted survival of yearling chinook salmon in the report's CSS model would only increase from 0.58% to 0.68%. This seems a small improvement that might well not be realized considering the variable effects of global warming and unpredictability of ocean conditions. Could the report include uncertainty estimates for these numbers? In another model, the maximum predicted fish return to the Lower Granite dam site would increase by a factor of 1.7. In other words, the predicted return would less than double not exactly overwhelming. The DEIS modeling does not indicate anything like restoring the historic salmon and steelhead runs as some have suggested.	Estimates of uncertainty were included in the later results from the CSS fish modeling group. These estimates have been included in Appendix E of the Final EIS. The co-lead agencies used high quality data and modeling to evaluate effects to salmon and steelhead from each alternative. The Lifecycle models from National Marine Fisheries Service (NMFS) and the CSS group are both peer-reviewed and regionally accepted models that have been used to predict the effects of actions on anadromous fish for many years. The comment is correct, the model results do not show great differences in juvenile survival among the alternatives. Still a 10 percent increase in juvenile survival would be a significant benefit for any of the ESA-listed salmon population. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of NMFS and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
5162	3	N/A	N/A	A major improvement in the DEIS would be to develop and include summary quantitative assessments of projected dam removal costs and of projected fish population increases. Another useful inclusion would be an assessment of how the dam removal would affect job numbers. The comments above apply mainly to the predicted long-term impact of breaching the LSR dams. The report also indicates a major adverse effect on fish populations in the short term during and following dam removal. How long would the transient effects persist, and how much would fish populations decline in this period? It seems worth noting that challenged species such as salmon-eating orca would also be negatively affected during the dam removal phase and recovery period. Could their short-term survival be assessed?	A summary of the environmental consequences is provided in Chapter 3, Table 3-1. This table provides an overview of the effects of the alternatives on the fish as well as the anticipated changes in costs to operate the system. The regional economic effects associated with the alternatives is described in Section 3.19.3 and Annex C of Appendix Q. The construction activity associated with dam breaching at the lower Snake River projects would be anticipated to support approximately 12,000 jobs over a 2 year period. Section 3.3 describes the near-term sedimentation effects following dam embankment breaching, which are expected to last up to 10 years as legacy sediment deposits within the reservoirs are incrementally eroded and re-deposited throughout the lower Snake River reach. The sedimentation and water quality effects of the dam breach on fish are described in Section 3.5. The estimated severity of the sediment pulse varies for the type of fish and the mitigation measures implemented under MO3. However, major short-term effects would occur due to the large amount of suspended sediment during dam breaching. There is the potential for large-scale mortality for any fish in the river during this construction work. The effects of MO3 on the orca are described in Section 3.6. The construction disturbance under MO3 would not affect habitat for the Southern Resident killer whales. Table 3-106 describes a minor effect to orca from changes in prey availability under MO3. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020).
5167	1	N/A	N/A	The initial concept that these dams provide flood control is not based on fact. Actually the reservoirs silt up and increase the potential for flooding. The silt needs to be constantly removed at a high cost.	The lower Snake River dams are not authorized for flood risk management and this is clearly stated in the EIS in Section 1.2. Chapter 7, Table 7-1, also indicates that there is no elevated risk to flooding in the lower Snake River reach for any of the alternatives examined in the EIS. Unlike free-flowing channels, in Lower Granite Reservoir the forebay elevation at the dam controls the energy grade-line of the water surface, and the reservoir is drawn down during high water events to ensure water levels remain low. Furthermore, the Walla Walla District of the Corps constructed 8 miles of levees around Lewiston as mitigation to help protect lives and property from potentially destructive high-water conditions after the dams were built.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The most recent dredging in the Lewiston area, has been to maintain a 14-foot depth in the Federal navigation channel, as discussed in the 2014 Programmatic Sediment Management Plan (https://www.nww.usace.army.mil/Missions/Projects/Programmatic-Sediment-Management-Plan/) and also referenced in the EIS.
5167	2	N/A	N/A	The reservoirs increase water temperatures which endangers the health and viability of androgynous species which need cool water to survive.	Many reservoirs within the Columbia River System exhibit the typical water temperature lag that is commonly seen in impounded waterbodies. The reservoirs tend to be cooler in the spring and warmer in the fall as compared to undammed rivers. Reservoirs do not necessarily increase water temperatures. In fact, data demonstrates that some reservoirs, such as Dworshak Reservoir, provide cold water and are operated to improve downstream water temperature conditions to support anadromous fish populations.
5167	3	N/A	N/A	Irrigation needs of crops to feed cattle is not sustainable. Hay and alfalfa are water hungry crops. We need to subsidize farmers so that they can shift to other human food crops.	NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. (see 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026). The mitigation requested is not within the co-lead agencies' current authorities.
5169	1	jimretired42@gmail.com	N/A	In the spring , summer of 2000 there was an abundance of fish. so much so the authorities increast the daily bag limit. Since that time our fish runs have been dwindling evey year until now they are in peril of vanishing completly. One reason is the California sea lion which has made its way up the Columbia River to the Bonnivile Dam and the Willamette Falls. These sea lions should be removed from the river by what ever means it takes and not allowed to return. Maybe we could herd a pod of Orcas up the river and they would take care of the sea lions.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including reduction of pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
5169	2	jimretired42@gmail.com	N/A	. Yes the dams have taken a toll on the fish but the Corps of Engineers have provided funds to build hatcheries to maintain the runs. Several of these hatcheries have been shut down and need to be reopened. I belive a lot of this is the lack of good judgement on the part of some poor leadership.	Hatchery programs are included in the No Action Alternative and would be expected to continue under the Preferred Alternative (PA), and Multiple Objective alternative 1, Multiple Objective alternative 2, and Multiple Objective alternative 4, and certain hatcheries would continue under MO3. No new hatchery programs are considered as mitigation under any alternatives, but MO3 does include increased hatchery production due to short-term impacts from breaching the four lower Snake River dams. Based on the anadromous fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as proposed under the No Action Alternative, and a number of other mitigation measures would continue as well.
5170	1	Michaeled223@comcast.net	N/A	Rather than proposing a meaningful alteration to hydro system operations to protect threatened and endangered salmon and steelhead, the Draft Environmental Impact Statement (DEIS) recommends only minor adjustments to the status quo, a routine that has cost billions of dollars, resulted in salmon and steelhead runs of perilously low levels, increased the extinction risk for orcas, and resulted in uncertainty for communities across the region. Similar plans have been rejected five times in a row by the federal courts. The DEIS preferred alternative based on flexible spill does not even provide reasonable assurance that it will avoid extinction, let alone recover Snake River salmon and steelhead to abundant, harvestable levels. Indeed, both the parties to the current, short-term Flexible Spill Agreement and respected scientists have asserted that flexible spill will not deliver the long-term relief these fish require. The intensifying impacts of a changing climate will further erode the benefits of flexible spill. There is a good chance this alternative will not meet the requirements of the Endangered Species Act and will likely land everyone back in court starting yet another cycle of expensive litigation that keeps the region mired in uncertainty	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Both human-caused and natural factors that are outside the responsibility and control of the co-lead Federal agencies, also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The CSS model, which includes latent mortality effects, predicts that median Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. That result, however depends upon the latent mortality hypothesis central to the CSS model being correct. To address this uncertainty and minimize risk, the Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or Total Dissolved Gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
5170	2	Michaeled223@comcast.net	N/A	The colder, more abundant and more undisturbed stream habitat in the Snake River Basin presents the greatest potential for wild fish recovery of any watershed in the Columbia Basin. For more than two decades, tribal, federal, state, and independent research has repeatedly confirmed that river restoration that includes dam removal will work. While this might have been a radical idea at some point in time, it is not any longer. Dam removals from Maine to Washington Stat have abundantly illustrated this now proven method to restore fish populations. Indeed, the DEIS itself recognizes that breaching the dams will deliver greater benefits to endangered Snake River fish populations, with greater certainty, than any other option. Several decades of failed recovery efforts should adequately illustrate that recovery of robust, harvestable levels of Snake River salmon and steelhead is not achievable with the dams in place.	Section 3.5.3.6 under the Larval Development/Juvenile rearing sub-heading (line 17110) of the Draft EIS describes that breaching the four lower Snake River Dams is estimated to increase the available spawning habitat for fall-run Chinook from 226 acres to 3,521 acres, an increase of 15 times the area available today. Shallow water rearing habitat is very important to juvenile fall Chinook. The Final EIS has been updated to more clearly articulate this. The EIS studied breaching the four lower Snake River dams as part of MO3. Many dam removal projects that have occurred across the United States have very different circumstances than what is contemplated in MO3. For example, the Elwha dam in Washington State, has little relevance to the lower Snake River dams. Elwha Dam had no passage and provided no economic benefits. In contrast, the lower Snake River dams provide upstream and downstream passage and also produce power and provide navigation and recreation opportunities. The EIS concluded MO3 would have greater improvements to certain salmon species in the lower Snake River. It did not conclude there was greater certainty of that result in MO3 over any other alternative. The conclusions were based on the ranges predicted in two independent models that have different parameters and limitations in their predictive capabilities. Because of delayed response time in MO3, and the potential severity of the short-term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Based on the EIS analysis, the Preferred Alternative would make a substantial contribution to improving Snake River anadromous fish runs. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2 percent (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
5171	1	tomstuart@cableone.net	N/A	I'm angry about the alternatives studied to date in the court-ordered EIS process, the analyses conducted, and the "preferred alternative" selected. Selection of alternatives: the agencies failed to evaluate or consider the option that would be most beneficial for ESA-listed fish populations in the Columbia basin: undamming the lower Snake River, while spilling to 125% TDG at Lower Columbia projects during the salmon migration. This option was widely discussed in many venues during the past three years, but was ignored in this EIS. Should we conclude then, that the object of this entire NEPA process was not to find a strategy that would actually restore endangered salmon?	Improving anadromous fish conditions were two of the eight multiple objectives of the CRSO EIS. The co-lead agencies disagree, however, that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125 percent Total Dissolved Gas (TDG) at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. MO3 and Multiple Objective alternative 4 (MO4), individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5 percent of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125 percent and breaching the four lower Snake River dams is unreasonable, and was not proposed as an alternative. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
5171	2	tomstuart@cableone.net	N/A	Second, agency leaders should be ashamed for failing to fully evaluate and incorporate the economic impact of the various alternatives on the sportfishing and commercial fishing enterprises of the NW. You've studied in great detail the impacts for energy production, shipping, and agriculture, albeit with some errors and exaggerations. But you've ignored fishery-based economies and tribal cultures -- the people, jobs, families, and towns that suffer the most with an FCRPS status quo that does not restore abundant salmon runs. The estimated contribution of fisheries in Idaho alone is over $757 annually, and over $2 billion region-wide. The Idaho Department of Labor estimated the Clearwater region of Idaho lost $8.6 million each month during the steelhead season curtailment and closure in 2019. Commercial fishers, sportfishing guides, outfitters, tackle shops, hotels, restaurants and businesses in every riverside town from Astoria OR to Stanley ID are suffering. How can federal agencies ignore those jobs, families and towns? Are they less important to the region? It is outrageous that you've ignored these people in this EIS, while favoring other interests.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the MOs, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. For MO1, MO2, MO4, and the Preferred Alternative (PA), the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the PA and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5. The EIS recognizes the economic and cultural importance of salmon and steelhead fisheries. The cultural significance and impacts of salmon and

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries Tribal interests are described in Section 3.15.4. Additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including Tribal interests (Section 3.11.3.7). Chapter 7 also includes impacts of the PA on fisheries.
5171	3	tomstuart@cableone.net	N/A	To rebuild those populations and the valuable fisheries they support requires a smolt-to-adult return rate (SAR) of 4% on average, within a 2-6% range for good and bad years. Your PA doesn't even come close, and in fact, predicts actual SARs under 1% about 40% of the time, pushing the fish even closer to extinction. The PA leaves Idaho salmon on an extinction path. The flex spill agreement reached two years ago was never intended to be the basis for long term salmon recovery; it is unacceptable, and not likely legal, to simply tweak the system and hope for a miracle. The failure to deal with a warming climate in any substantive way is an egregious fault in the EIS, and in the PA.	The 2 to 6 percent Smolt-to-Adult return rate (SAR) target referenced in this comment refers to the Northwest Power and Conservation Councils (Council's) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia River Basin, the Councils recovery goals are shared by many parties. Based on the EIS analysis the Preferred Alternative will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which only contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon State water quality standards had to be changed to implement the new spill regime. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. For the Preferred Alternative, the CSS model, predicts that SARs will increase for both Snake River spring Chinook and steelhead with median values well above 2 percent (the lower end of the Council's recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address the uncertainty due to the different model results, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, and Total Dissolved Gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Finally, the climate effects to resources affected by CRS operations, maintenance, and configuration are discussed in Chapters 4 and 7.
5172	1	markham_julie@hotmail.com	N/A	Fisheries Biologists have been studying the causes of decline in Chinook salmon and Steelhead ever since they were listed back in the early 1990's, back when I started working as a Fisheries Technician for the Salmon Challis National Forest 28 years ago now, and they have always known that 80% to 90% of our loss of anadromous fish come from the dams slackwater and turbine mortality on outmigrating smolts. Back when they were listed we already had incredible amounts of good habitat for them to spawn and rear in all five states: Washington, Oregon, Idaho, Montana and Nevada as well as in Canada, so habitat has never been a limiting factor. I personally helped survey the amazingly beautiful and abundant anadromous habitat we had in the Frank Church River of No Return Wilderness Area. With ocean conditions changing it adds another hit on their survival. We can't fix the ocean, but we can remove a dam.	The commenter's assertion that biologists have always known that 80 to 90 percent of losses to anadromous fish come from the dams is in error. The run of river dams in this EIS are required to maintain juvenile fish survival for downstream at a rate of over 93 percent. Overall system survival has been, and continues to be, approximately 50 percent. This accounts for all forms of mortality, including predation. Some unknown degree of predation would continue to impact survival even under a dam breach scenario. Upstream survival of adult salmon and steelhead is between 80 and 90 percent and has been as high as 99 percent for some species on some years. Extensive work has been conducted to improve the survival of these species at CRS dams. This work continues with the installation of Improved Fish Passage turbines at Ice Harbor Dam. Recent testing shows juvenile survival rates through these turbines of over 98 percent. While the EIS did not evaluate habitat needs, recent presentations from the states of Washington, Idaho and Oregon reported that between 70 and 80 percent of the streams in these states have passage issues, either through perched culverts or a lack of diversion screens to protect outmigrating smolts. In one study in the Salmon River drainage, one small stream diverted nearly all fish into irrigation channels with very few passing downstream. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes the measure to breach the four lower Snake River dams. However, the Preferred Alternative also meets most other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend the measure to breach the four lower Snake River dams within MO3, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
5172	2	markham_julie@hotmail.com	N/A	I would like to see us adopt a strategy that is being used for the dams on the Kalamath. The formation of a corporation with the whole objective of collecting non-profit volunteer funding for the cost of removal and becoming the experts through hiring biologist, hydrologist and designing plans on the process of dam removal. The Federal government could and should be funding this effort but are obviously still reluctant. The four lower Snake dams are known to be the ones to remove. They are aging and cost rate and tax payers millions if not billions annually in maintenance and mitigation. It might come down to cost benefit where it might be better financially for BPA/Federal government to turn over licensing of one or more of these dams to a corporation for eventual removal. I've always hoped we could keep hydropower in the grid mix because it is a clean and no-brainer safe power source, so still think there might be some innovation, something new that needs to happen, using BPA/BOR/USACE and outsourced multi agency, multi entity think-tank - expertise on turbines and hydrology; to lower dams to more of river flow level, or remove them and have power generation with a portion of the flow off to the side. Irrigation water could be lifted from the river with pumps or simply tiered paddle wheels. With other power sources coming on line we shouldn't need as much of it as hydropower and we could fill in power needs during low flows during the summer use using locally at place of use - generated solar and wind. Bottom line though is we definitely need dam removal to save these fish. I absolutely will not accept an option that suggests extinction as inevitable. I've worked too hard too many years for this.	The co-lead agencies analyzed the effects of breaching the earthen portions of the four Lower Snake River dams in MO3. Chapter 3 describes effects to hydropower, irrigation, fish and all other affected resources and provides a cost analysis for all the alternatives. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. The Preferred Alternative also meets most other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effect to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend the measure to breach the four lower Snake River dams within MO3, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Different models predict different long-term survival benefits to ESA-listed species from breaching the four lower Snake River dams, benefits that can contribute to recovery. Under the National Marine Fisheries Service (NMFS) COMPASS model, juvenile Snake River Spring/Summer Chinook in-river survival would improve by 9.6 percent due to dam breach, which is a 19 percent relative increase over the No Action Alternative. The NMFS Lifecycle model predicts an increase in adult returns of 13.6 percent for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88 percent to 1 percent). Results for Snake River steelhead are similar (10 percent absolute improvement, or 23 percent relative juvenile survival increase; Smolt-to-Adult return rates (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River spring/summer Chinook is predicted to improve by 10.4 percent due to dam breach, which is an 18 percent relative increase over the No Action Alternative, while SARs would increase by 115 percent (from 2 percent to 4.2 percent). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8 percent which is a 46 percent relative increase over the No Action Alternative. The CSS model also predicts that SARs increase by 177 percent (from 1.8 percent to 5 percent). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four lower Snake River dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 Draft EIS, because the four lower Snake River dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four lower Snake River dams represent 90 percent of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170, Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
5173	1	N/A	N/A	Historically half of all the salmon returning to the Columbia Basin were bound for the Snake River. But after the river was dammed more than half a century ago, the wild salmon runs plummeted and left the orcas with fewer fish to eat. Despite the fish ladders and the current interim spill measures, dams continue to cause serious salmon declines by directly killing and preventing their migration. Breaching these dams will cut dam-caused mortality by at least 50%.	The commenters mention of 50 percent mortality is inconsistent with the fish analysis provided in the EIS in Sections 3.5 and 7.7.4. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Regarding orcas: the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020).
5173	2	N/A	N/A	I am also very disappointed that the DEIS failed to fully or accurately consider southern resident orcas. The DEISs treatment of orca is, in fact, misleading and inaccurate. The DEIS claims that salmon from the Snake River are not important to the orcasclaiming that they comprise only a small percentage of the southern resident orca's overall dietand that neither the preferred alternative, nor dam removal, would appreciably benefit orca. This is patently false and ignores analysis from orca scientistsand even the agencies' own analysisthat shows the Snake and Columbia basin salmon are important to the orcas. These orcas primarily eat Chinook salmon and forage for these fish from central California into the Salish Sea. The Columbia basin supports salmon runs that the orcas have relied on for centuries, and, according to a study by the National Oceanic and Atmospheric Administration (NOAA) and the Washington Department of Fish and Wildlife, two of the ten highest priority salmon runs for the southern residents are Snake River runs. Historical evidence indicates that prior to the Snake River dams being built, there were many more Snake River salmon, and that these fish likely constituted a larger portion of the orcas' diet. Once-abundant species such as Chinook salmon, which make up 80 percent of an orca's diet, are only returning at a small fraction of historic levels. Starving female orcas are experiencing high rates of pregnancy loss, a heartbreaking statistic that was starkly illustrated recently by a grieving mother who refused to let her dead newborn calf go.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5173	3	N/A	N/A	abundant salmon runs would enable orca to access a historically important part of their diet, particularly at critical times of the year when female orcas are pregnant. The country's leading southern resident orca scientists have clearly stated that the four lower Snake River dams must be breached if we hope to prevent the extinction of these orcas. Scientists from the Fish Passage Center have stated that breaching all four of these dams would result in roughly one million adult Chinook salmon returning to the mouth of the Columbia River, providing a significant and important source of food for endangered southern resident orcas. The DEIS itself recognizes that breaching the dams will deliver greater benefits to endangered Snake River fish populations, with greater certainty, than any other option. With only 72 southern resident orcas left in the wild, there is little time to act and prevent their extinction. A restored Snake River is the only action that will enable substantially increased abundance of salmon and allow for an increase in overall food supply for orca. Moreover, restored abundance will also benefit sport, commercial, and tribal fishing economies and communities.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The determination for SRKW in regards to MO3 was based on the following facts: the population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5173	4	N/A	N/A	It is also important that we protect and restore salmon runs throughout the orcas' seasonal range. Typically, the southern residents forage for salmon off the west coast of the U.S. in the winter and spring. According to GPS data from NOAA, they spend a considerable amount of time at the mouth of the Columbia River foraging for salmon returning to both the Columbia and Snake Rivers to spawn. Despite the scientific consensus that orcas rely on Snake River salmon and the hundreds of thousands of comments the agencies received about orcas, there were roughly two paragraphs about the orcas in the entire 7,584-page document. I strongly urge the agencies to update this section of the DEIS and reevaluate the impact of all the alternatives on southern resident orcas.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5173	5	N/A	N/A	The agencies also failed to fully analyze the economic benefits of dam breaching, particularly for tribal, commercial, or recreational fishing businesses. When discussing the costs of replacing the energy from these dams with other renewable energy sources, the agencies grossly over-estimated the costs. A report from the Northwest Energy Coalition shows that through strategic investments, the energy produced by these dams can be replaced at a miniscule cost to ratepayers while also improving the reliability of the electrical grid. The DEIS also did not accurately assess the projected costs associated with maintaining the four lower Snake River dams.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. Section 3.11.3.7 describes the potential economic impacts to tribes related to recreation. The EIS analyzed the effects on regional reliability if the four lower Snake River dams were breached in MO3. To maintain regional power reliability at the No Action Alternative levels, additional replacement resources would be necessary. The EIS considered two resource portfolios to replace the power output of the lower Snake River dams: a least-cost conventional portfolio (natural gas) and a zero-carbon portfolio (primarily solar). See Draft EIS, Section 3.7.3.5, at Pages 3-904-910. Under both of these replacement portfolios, however, regional power rate pressure increases considerably. The rate impacts of these replacement resources, which includes cost savings from breaching the four lower Snake River dams, is described in Section 3.7.3.5, Table 3-166, pages 3-920-924 in the Draft EIS. As described in the EIS, even with the cost savings associated with reductions in dam operating and fish and wildlife mitigation costs, the net impact on power rates is in the range of between 13-50 percent, for zero carbon resources replacements, and 4-10 percent, for natural gas/least cost replacements. The EIS considered the Northwest Energy Coalition (NWEC) study cited by the commenter. See Draft EIS, Section 3.7.3.1, Step 3, at page 3-820, and Section 3.7.3.5, Related Study, at page 3-913 in the Draft EIS. However, that study is not directly comparable with the EIS for several reasons, including that the EIS has a broader scope and relies on more recent regional load and resource availability and costs data. See Appendix H, Power and Transmission, Section 2.4, in the Draft EIS.
5173	6	N/A	N/A	The DEIS also fails to meet tribal cultural, health, and economic needs, or treaty trust obligations. For tens of thousands of years, Native peoples have lived with abundant salmon. Restoring plentiful salmon to the Columbia and Snake rivers is not just ecologically important, it is an environmental justice issue.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The treaties bind all parties and are the supreme law of the land. The co-lead agencies recognize and respect that supremacy. In terms of honoring our treaty obligations, the co-lead agencies included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The purpose of the Environmental Justice analysis included in Section 3.18 of the Draft EIS is to determine "whether there may be disproportionately high and adverse human health or environmental effects on minority populations, low-income populations, or Indian tribes (CEQ 1997). The environmental justice analysis considers the extent to which the alternatives have the potential to affect the availability of fish for commercial, ceremonial and subsistence fishing for Indian tribes, relying on analysis presented in the Section 3.15.4 of the fisheries analysis as well, in making this determination.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					In addition, Section 3.17 of the Draft EIS discusses how the analysis evaluated impacts to tribal interests, including treaty rights. Where applicable or pertinent for specific EIS resources, the EIS described how tribal interests would be impacted by the different action alternatives in Chapters 3 and 7. Further, impacts to cultural resources are considered in Section 3.16, impacts to tribal health and economic needs are evaluated in Section 3.18 Environmental Justice, and impacts to fisheries are addressed in Section 3.15.
5177	1	jtmaxwell08@gmail.com	N/A	Your alternatives do not include the breaching of only 1 of the 4 dams as a potential alternative, why? You immediately discount breaching based off issues related to power generation and GHG without giving any evaluation to renewable energy as an alternative to breaching. Alternative energy can account for 600 MW (1 dam) and would also keep Ice Harbor in place for grid connectivity. Did you make this choice because you had a pre-determined preferred alternative, and only taking out one dam and seeing if it benefits endangered species would be too competitive of an option compared to the preferred alternative?	It is accurate that the co-lead agencies did not consider dam breaching of only one of the four Lower Snake River dams. The co-lead agencies instead proposed an alternative that evaluated normative river flows in the lower Snake River, which responded to direction from the U.S. District Court for the District of Oregon's Order and Opinion and comments received during scoping to evaluate breaching all four dams. This allowed the agencies to analyze what the greatest extent of beneficial and adverse impacts to affected resources would be if all four lower Snake River dams were breached. Breaching one or two of lower Snake River dam would not allow the co-lead agencies to operate for navigation in most situations (except in high flow situations), would likely not meet the objectives for greenhouse gas or power reliability, while also not likely making a substantial change for migrating salmon in the Snake River based on analysis of breaching all four projects and in comparison to other alternatives. The United States Federal government supports the development of alternative forms of energy through many different programs and policies. For example, the Bonneville Power Administration also has a robust conservation program, from which about 90 aMW in conservation are saved a year. Further, when acquiring long-term resources, the Bonneville Power Administration statutory directives give priority to conservation and renewable resources. The analysis for MO3 demonstrates what types of resources would be needed to replace the key attributes of the four lower Snake River dams. Included in this analysis is a resource portfolio made up of alternative forms of energy (i.e., wind, solar, and batteries). As described in Section 3.7, and Chapter 7, the adverse reliability and upward rate pressure impacts from breaching the four lower Snake River dams support retaining these resources over other alternative forms of energy.
5177	2	jtmaxwell08@gmail.com	N/A	Water temperature and total dissolved gas concentrations have no solution in your collaborative approach. That is what is killing the fish and you acknowledge your cant fix the problem and give no guarantee the preferred alternative will do so in future.	The EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives' effects on Snake River stocks, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Total Dissolved Gas (TDG) levels are regulated under the Federal Clean Water Act, and administered by the States. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125 percent of saturation on fish and other aquatic organisms. Based on this reassessment Oregon issued a 5-year "standard modification" and Washington issued a permanent rule change, approved by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125 percent. However, given the uncertainty in the effects, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. Based on the EIS analysis the Preferred Alternative will make a substantial contribution to improving Snake River anadromous fish runs. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2 percent (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
5177	3	jtmaxwell08@gmail.com	N/A	You purposely gloss over and avoid addressing this issue because your solution doesnt work (despite supposedly having used a collaborative approach to address concerns about river operations the last several years). Your report is a failure for this reason and shows that you did not have enough time to complete the report and do a full analysis. That or you were under politic pressure not to avoid alternatives like partial breaching. Is that due to the new time restrictions on EIS documents placed in by this administration or were you just oblivious?	The co-lead agencies appropriately analyzed all direct, indirect and cumulative effects to resources affected by Columbia River System operations, maintenance and configuration and presented this information to the public in the Draft EIS. The co-lead agencies instead proposed an alternative that evaluated normative river flows in the lower Snake River, which responded to direction from the U.S. District Court for the District of Oregon's Order and Opinion and comments received during scoping to evaluate breaching all four dams. This allowed the agencies to analyze what the greatest extent of beneficial and adverse impacts to affected resources would be if all four lower Snake River dams were breached. Breaching only one or two of lower Snake River dam would not allow the co-lead agencies to operate for navigation in most situations (except in high flow situations), would likely not meet the objectives for greenhouse gas or power reliability, while also not likely making a substantial change for migrating salmon in the Snake River based on analysis of breaching all four projects and in comparison to other alternatives.
5188	1	N/A	N/A	The Draft EIS proposes a plan of action that does not significantly modify previously utilized methods such as increasing spill rates or collecting and transporting juvenile salmon and steelhead around dams. The current and proposed plans will not achieve consistent smolt-to-adult return rates (SARs) of 2%-6% which are necessary to rebuild the Snake and Columbia River Salmon and Steelhead. Nor will they mitigate the documented rise of water temperatures at the dams proposed for removal. The U. S. Environmental Protection Agency (EPA) 2003 modeling found that the water temperature in an undammed river could reduce water temperatures up to 6.8 degrees increasing the survival rate of salmon species. Numerous scientific reports including the 1996 Return to River, NOAA Fisheries in the 2000 Biological Opinion for Federal Columbia River Power System (FCRPS) operations, the 2000 U.S. Fish and Wildlife Service report to the U.S. Army Corps of Engineers and the interagency Comparative Survival Study (CSS) of 2017, all identify the benefits for salmon survival which would occur after the removal of the four lower Snake River dams.	The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon State water quality standards had to be changed to implement the new spill regime. Section 7.7.4.1. describes that: The transport of juvenile salmon collected at Lower Granite, Little Goose, and Lower Monumental projects could begin as early as April 15, approximately two weeks earlier than current fish transport operations described in the No Action Alternative. Transport operations would end, September 30 at Lower Monumental and October 31 at Lower Granite and Little Goose. Collected juvenile fish would be transported to a location below Bonneville Dam via barge or truck on a daily or every-other-day schedule, depending on the numbers of fish collected at the collector projects. This action could increase the number of juvenile fish transported to the estuary. Regarding water temperatures under the measure to breach the four lower Snake River dams in MO3, the EIS analysis indicates that night time summer water temperatures, as well as fall water temperatures, would be cooler than No Action Alternative conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The models showed minor changes in the Columbia River under this alternative. Regarding the analysis of effects, the co-lead agencies used the high quality information in the CRSO EIS. Specific to salmon and steelhead, the co-lead agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0 to 2.7 percent for Chinook, a 35 percent relative increase. The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
5188	2	N/A	N/A	There are other issues that are relevant to the removal of these dams. These dams do not provide flood control. In fact, they are creating a risk to cities such as Clarkston and Lewiston because silt is accumulating behind the Lower Granite Dam. This is raising the level of the river and thus increasing the risk of flood. Among the options being considered by the Corps of Engineers is raising levees, dredging and other measures. The volume of sediment may be not be solvable by dredging.	The lower Snake River dams are not authorized for flood risk management and this is clearly stated in the EIS in Section 1.2. Chapter 7, Table 7-1, also indicates that there is no elevated risk to flooding in the lower Snake River reach for any of the EIS alternatives. Unlike free-flowing channels, in Lower Granite Reservoir the forebay elevation at the dam controls the energy grade-line of the water surface, and the reservoir is drawn down during high water events to ensure water levels remain low. Furthermore, the Walla Walla District of the Corps of Engineers constructed eight miles of levees around Lewiston as mitigation to help protect lives and property from potentially destructive high-water conditions after the dams were built. The most recent dredging in the Lewiston area, has been to maintain a 14-foot depth in the Federal navigation channel, as discussed in the 2014 Programmatic Sediment Management Plan (https://www.nww.usace.army.mil/Missions/Projects/Programmatic-Sediment-Management-Plan/) and also referenced in the EIS.
5188	3	N/A	N/A	Also these options will cost millions of dollars over the long term and also pose threats to fish, wildlife and recreational opportunities. These dams only provide 4% of power and the Bonneville Power Administration (BPA) has surplus dam-produced power currently. Additionally, renewable wind and solar and natural gas thermal energy are available at cost-effective pricing currently. Expansion of these energy sources plus dam removal work will create jobs. Funding for enhanced rail transport may or may not be necessary because freight transport on the Lower Snake River has been in decline for decades because fewer items like paper, pulp, logs, etc. are shipped on barges. Crops and other products can be freighted by rail or trucked to Pasco, WA for barge loading or railed and trucked to Portland for distribution. Improvements in the rail system and highways to replace the barges is affordable using moneys necessary for the maintenance of these four dams and would benefit not only the regions farmers but also businesses, manufacturers and communities from Spokane to eastern Washington.	While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville markets power. As explained in Section 3.7.3.5 of the Draft EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are among the most valuable projects in the FCRPS. The four lower Snake River dams produce around 1,000 aMW of power, which is approximately 12 percent of the average power produced by the FCRPS. See EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159 in the Draft EIS. Losing this amount of power is equivalent to losing power capable of serving 730,000 homes in the Northwest. See EIS, Section 3.7.3.5, Summary of Effect, page 9-935 in the Draft EIS. Whether Bonneville will have surplus power to sell is dependent upon water conditions and availability of generation. In most average water years, Bonneville will have surplus or secondary power to sell on the open market. This type of power, however, is made on an as available basis and is not the same quality or dependability as firm power, which is power available under extremely low water conditions. See EIS, Section 3.7.2.7, Firm Power, pages 3-802-803 in the Draft EIS. The four lower Snake River dams supply both firm power and secondary power to support Bonneville's power obligations. See Draft EIS, Section 3.7.2.7, Table 3-111. As such, breaching the four lower Snake River dams would have a direct and substantial impact on the supply of Federal power and require replacement resources (either natural gas or renewables), placing upward pressure on power rates. The rate impacts of these replacement resources, which includes the cost savings from the breaching of the four lower Snake River dams, is described in Section 3.7.3.5, Table 3-166, pages 3-920-924 in the Draft EIS. As described in the EIS, even with the cost savings associated with reductions in dam operating and fish and wildlife mitigation costs, the net impact on power rates is in the range of between 13-50 percent (for zero carbon resources replacements) and 4-10 percent (for natural gas/least cost replacements). Potential effects from removal of the lower Snake River shallow draft barge are described in Section 3.10.3.5, Navigation and Transportation analysis for MO3. The EIS finds that potential improvements to the rail or road system (or both) are highly dependent on how rail rates would change without lower Snake River shallow draft. How the rates would change without barging can not be known with certainty and would ultimately affect the rail and the road systems. The EIS acknowledges that depending on how rail rates respond to breaching of the four lower Snake River dams, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required.
5198	1	debbie@alexanderzoo.com	N/A	We can provide better fish ladders and other solutions to keep the fish from declining.	Alternatives were developed from actions identified in public scoping and in meetings with regional scientists and biologists. New fish passage structures and improvements to existing structures were discussed and some were included in the Multiple Objective alternatives. Other measures were removed from consideration because they were not technically feasible. See Chapters 2 and 7 for additional information on structural measures included in the MOs, including the Preferred Alternative.
5208	2	dinoatgs@gmail.com	N/A	The 4 lower Snake River dams do provide electricity and navigation benefits, but I would speculate that alternatives to those dams could be developed. It will not be inexpensive, but if a honest cost benefit-analysis of improved anadromous fish runs compared to the current situation is done, that removing the dams will prove over time to be the most beneficial solution to society.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level. The EIS does not employ a cost-benefit framework for decision-making. This is because, consistent with NEPA analysis framework, the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. Consequently, a focus solely on the monetized economic costs and benefits would exclude important tradeoffs associated with the alternatives communicated in the EIS, including effects on fish. Furthermore, the EIS evaluates the performance of the CRSO EIS alternatives with respect to EIS objectives, for example improving fish passage and survival, providing for reliable power generation, and minimizing greenhouse gas emissions. Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives.
5212	1	N/A	N/A	The proposed EIS does not adequately address the impacts of these dams on the salmon and the environment. Nor is there evidence to presume that minor changes to the plan will be effective. Even though billions of dollars have been spent on mitigation of the environmental effects of the dams, salmon and steelhead are at some of their lowest levels on record, orcas are on the edge of extinction, and the plan has been invalidated five times in federal courtits time to come up with a new approach.	The EIS uses high quality information in analyzing effects to resources from the alternatives evaluated. Modeling from two peer reviewed and regionally accepted models was used to compare the alternatives' effects to salmon, while qualitative analyses conducted by regional teams were used to evaluate effects to species without accepted models. The Preferred Alternative is not simply a minor change to the plan. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The CSS model, which includes latent mortality effects, predicts that median Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (well within the range of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions would generally continue to ensure compliance with the ESA. Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the CRS project. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
5212	2	N/A	N/A	Exceeding the established water quality standard of 68 degrees F has been a long-standing problem. Studies indicate that dam removal, in returning the natural flow of the river, will cool the waters by as much as 12 degrees F and address this issue. The dam removal will also recover 15,000 acres of riverine habitat and agricultural land.	The analysis of MO3, which includes a measure to breach the four lower Snake River dams, shows that the lower Snake River water temperature regime would reflect that of a natural river system, without the water temperature lagging effect that reservoirs create. Spring water temperatures would warm faster, while fall water temperatures would cool faster, as compared to current conditions. The EIS analysis also indicates that summer water temperatures would cool to a greater extent at night, but some exceedances in the 68F water quality standard would still occur, especially during hot weather events. Breaching the four lower Snake River dams would not return the river to natural flow conditions since there would still be multiple hydroelectric facilities (dams and impoundments) upstream of the lower Snake River reach that would effect the hydrology of the system. The EIS analysis does not support the portion of the comment that references recovering 15,000 acres of riverine habitat and agricultural land under MO3. Section 3.5.3.6 under the Larval Development/Juvenile rearing sub-heading (line 17110) of the Draft EIS describes that breaching the four lower Snake River dams is estimated to increase the available spawning habitat for fall-run Chinook from 226 acres to 3,521 acres. Section 3.12.3, documents for MO3 in Region C, pumps are unable to deliver water to an estimated 47,926 acres.
5212	3	N/A	N/A	The dams are a flood threat to cities of Clarkston and Lewiston due to growing sediment deposits. It is agreed that even costly dredging would not be enough to solve the sediment problem. And, cities do not want levees built to cut them off from the river.	The lower Snake River dams are not authorized for flood risk management and this is clearly stated in the EIS in Section 1.2. Chapter 7, Table 7-1, also indicates that there is no elevated risk to flooding in the lower Snake River reach for any of the EIS alternatives. Unlike free-flowing channels, in Lower Granite Reservoir the forebay elevation at the dam controls the energy grade-line of the water surface, and the reservoir is drawn down during high water events to ensure water levels remain low. Furthermore, the Walla Walla District of the Corps of Engineers constructed eight miles of levees around Lewiston as mitigation to help protect lives and property from potentially destructive high-water conditions after the dams were built. The most recent dredging in the Lewiston area, has been to maintain a 14-foot depth in the Federal navigation channel, as discussed in the 2014 Programmatic Sediment Management Plan (https://www.nww.usace.army.mil/Missions/Projects/Programmatic-Sediment-Management-Plan/) and also referenced in the EIS.
5213	1	g_bailey@stjohncable.com	N/A	As a Whitman county wheat grower, I want to keep a functional river transportation system to get our product to market. Washington wheat growers export nearly 90% of their wheat overseas, and both the river and railroad are necessary to efficiently move products to market as well as deliver inputs necessary for our operations. Losing either system would leave us as captive shippers, and transportation costs would certainly increase dramatically. The dams provide much more than just transportation for ag products. The hydropower supplied by the dams provide the region with clean, carbon free electricity. Irrigation provided by snake river waters benefit many farmers who raise row crops and grapes. The river also provides many recreational opportunities.	As described in Section 3.10.3.5, Navigation and Transportation, the analysis of MO3, which includes the measure to breach the four lower Snake River dams, finds that average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are double, depending on their specific location and other conditions. The statement that the four lower Snake River dams generate carbon free power is consistent with discussions in the EIS, as is the statement recognizing the transportation and irrigation benefits of the system. MO3 was not identified as the Preferred Alternative in the Draft EIS.
5213	2	g_bailey@stjohncable.com	N/A	Overfishing, pollution, ocean conditions, changing climate, predators, and dams have all contributed to the challenges faced by the salmon. River systems without dams have also experienced declining fish runs. Improvements in fish passage, increasing hatchery output, and changing stream flows are all important to increase salmon survival	The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams, including those mentioned in this comment. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service website at: https://www.nwfsc.noaa.gov/research/index.cfm. Chapters 6 and 7 also discuss the impacts from past, present and reasonably foreseeable future actions on anadromous fish.
5229	1	frsuter@comcast.net	N/A	There are stories of the millions of salmon that migrated the Columbia and Snake Rivers before all of the dams were built. Today, we breathe a sigh of relief if the winter run of chinook salmon reaches 60,000. Snake River sockeye were listed as endangered since 1991; Snake River chinook were listed as threatened since 1992. In 1993, US District Judge Malcolm F. Marshs ruling found that the National Marine Fisheries Service - instead of looking for what could be done to protect the species from jeopardy - took action that was too heavily geared towards a status quo that has allowed all forms of river activity to proceed in a deficit situation - that is, relatively small steps, minor improvements and adjustments when the situation literally cries out for a major overhaul. (This was sourced from the US District Court, District of Oregon, May 2016 finding). Now, TWENTY-SEVEN YEARS LATER, on page 18 of the DEIS Executive Summary, Columbia River System Operations Objectives are stated as: Improve Juvenile Salmon Improve Adult Salmon Improve Resident Fish Provide a Reliable and Economic Power Supply Minimize GHG Emissions Maximize Adaptable Water Management Provide Water Supply Improve Lamprey Where in the DEIS Executive Summary, under Columbia River Systems Operations Objectives are the objectives: Restore Juvenile Salmon and Steelhead populations Restore Adult Salmon and Steelhead populations Restore Resident Fish populations Facilitate the recovery of threatened and endangered species that have inhabited the Columbia and Snake Rivers Provide a Reliable and Economic Power Supply Minimize GHG Emissions Maximize Adaptable Water Management Provide Water Supply Restore Lamprey populations To abide by the US District Courts order, shouldnt these be your objectives? How long are the agencies involved in Columbia River Systems Operations going to disregard repeated court orders to address the significant decline of Columbia and Snake River salmon and steelhead? The fish are facing extinction in these waters and the agencies answer is to continue with the status quo - a status quo that has placed these fish in this perilous situation. The Preferred Alternative pits two diametrically opposed objectives against each other - increasing spill to aid juvenile salmon migration against the objective to provide reliable power supply. The first time these two objectives face a challenge (drought caused by climate change, for example), which objective will take precedence? We all know the answer to that - salmon and steelhead loose.	The CRSO EIS documents the assessment of benefits and impacts of changes to the operations of the 14 Federal projects of the CRS. Using a multi-disciplinary approach and with the coordination and consideration of cooperating agencies and Tribes, as well as public stakeholder input, and by using high quality information, the co-lead agencies developed the Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies, working with the cooperating agencies, developed the objectives for operating the system, using the Purpose and Need Statement and input from Tribes, cooperating agencies, and the public. The eight objectives are what the Federal agencies are trying to accomplish (the why). They are statements of the desired outcome of the EIS, as identified by the Federal agencies and from scoping comments. An example of an objective is to improve ESA-listed anadromous salmonid adult fish migration within the project area. Objectives do not include language to "restore" populations. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to minimize impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. As required by NEPA, the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, and fully described by resource and alternative in Chapter 3, 4, 6, and 7. Effects are summarized by resource and alternative in Table 3-1 in the Draft EIS, and presented for comparison in Tables 7-1 and 7-55 in the EIS. Effects specific to anadromous fish are described in Sections 3.5.3 and 7.7.4. Table 3-61 in the Draft EIS compares expected survival by alternatives, and Table 3-62 in the Draft EIS provides a comparison of the alternatives specific to anadromous fish. Impacts to CRS affected resources from climate change and cumulative effects are described in Chapters 4, 6, and 7. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets.
5229	2	frsuter@comcast.net	N/A	Where in the DEIS is the study that values the economic loss, in terms of revenue, jobs and loss of life should the continued status quo operation result in the collapse of the food chain? Where in the DEIS is the study that values the jobs created by improving the electrical grid to satisfy the addition of renewable energy sources (wind and solar)? Where in the DEIS is the study that values the jobs created by producing energy storage systems that facilitate the use of wind and solar energy sources? Where in the DEIS is the study that values the impact on GHG emissions that embrace renewable energy sources or the latest energy efficient appliances and building codes? Or the positive impact on the rail system? Or the electrification of the rail system?	Estimating the potential regional economic benefits of clean energy development, including job creation, that are described in the comment are beyond the scope of the EIS. The EIS acknowledges the importance of renewable energy for achieving clean energy goals, and evaluated the change in greenhouse gas emissions for the two resource replacement portfolios evaluated under each alternative. Under Multiple Objective alternative 1, Multiple Objective alternative 3, and Multiple Objective alternative 4, the EIS finds an increase in emissions, which were monetized based on the social cost of carbon. See Section 3.8.3.5 pages 3-1014 and 3-1017 in the Draft EIS for the results of these analyses.
5255	1	2015johnpwells@gmail.com	N/A	The DEIS must include a comprehensive economic analysis of Idaho'ssportfisheryand itspotential if abundant wild salmon and steelhead runs are restored. In 2003 during an average return year, in the Clearwater region alone salmon and steelhead fisherman spent $8.6 million a MONTH. In 2019 anglers of all persuasions spent a total of $750 million in the entire STATE in the YEAR. Salmon and steelhead fishing supports guides, outfitters and businesses in river towns throughout the State of Idaho. The people and towns that largely depend on wild salmon and steelhead for their livelihoods have been given less than equal consideration in the DEIS and your current PA.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
5255	2	2015johnpwells@gmail.com	N/A	The dam breaching alternative is the only option that meets life-cycle survival criteria, achieves meaningful recovery and minimizes the jeopardy of extinction. The science indicates that only the removal ofthe dams will result in SARs that meet the regional goals of 4%. A SAR range of 2% to 6% has been deemed necessary for recovery to sustainable harvestable numbers of fish. Breaching is the only alternative that adequately minimizes the risk of extinction for Snake River stocks as a baseline which is required by the DEIS.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.

					With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of the Northwest Power and Conservation Council's recovery targets for the region), increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia River Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The 4 percent average SARs target and range of 2 percent to 6 percent referenced, refers to the Northwest Power and Conservation Councils (Council's) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia River Basin, the Councils recovery goals are shared by many parties. Based on the EIS analysis the Preferred Alternative will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects.
5255	3	2015johnpwells@gmail.com	N/A	Your alternative MO3 needs to include an honest cost-benefit analysis of the 4 LSRD and the powerthey generate. Purchasing power on the open market in today's market placeis significantly cheaper than than estimated annual LSRD maintenance and operations. Turbine replacements and maintenance in the next decade for the 4 dams will cost tens of millions of dollars in addition to the on-going mitigation efforts which have failed. Removing the 4 LSRD is both a win for the fish and a long term financial win for the BPA.	The findings of this EIS do not support these claims. MO3 showed significant rate impacts relative to the No Action Alternative, after accounting for avoided spending at the four lower Snake River dams under the alternative. See Draft EIS, Section 3.7.3.5, Table 3-166. Additionally, a calculation of a benefit-to-cost ratio is not a requirement of NEPA or the basis of alternative selection under NEPA (see 40 C.F.R. 1502.23). Instead, the direct and indirect effects to the natural and human environment were evaluated, including some effects that were evaluated quantitatively and monetized, while others were evaluated qualitatively. The EIS estimates the costs to operate the Columbia River System dams, as well as the costs to the power system that would occur if the four lower Snake River dams are breached under MO3. Further, the commenters suggestion that the firm power produced by the four lower Snake River dams could be replaced with spot market purchases at substantially lower prices is not supported by the analysis in the EIS. The power provided by Bonneville from the collective Federal Columbia River Power System, which includes the four lower Snake River dams, is sold as firm power to its customers under long-term contracts. See Draft EIS, Section 3.7.2.7. Under these contracts, Bonneville meets its customers firm power load with firm power in every hour as determined by the customers contracts. Power sold at spot or market prices are generally sold for shorter durations and are generally sold in blocks or whole quantities. As such, these spot power prices are not a reasonable comparison to the power sold by Bonneville, because there are a variety of additional benefits from firm Federal power, such as reliability and dependable supply at a fixed price as opposed to the volatility of the market. Although the turbines at the four lower Snake River dams are between 41 and 50 years old and nearing their design lives, there are no plans for any immediate replacements. Investment decisions are driven by equipment condition, probability and consequence of failure and, as such, it is common for equipment to be in service well past its design life. For example, some turbine runners at McNary dam will be over 70 years old by the time the replacement project is complete. Long-term planning analyses that calculate the optimal economic time to replace equipment based on current and expected equipment condition, probability of failure and outage consequence, point to the late 2030s as the earliest replacement dates for major powertrain equipment at the four lower Snake River dams. Most turbine replacements are forecasted between the 2040s and 2060s which would put the turbines at the four lower Snake River dams at about the same age at replacement as McNary. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170 in the Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review , the Headwater/Lower Snake Asset Class is forecast to have a 50-year levelized cost of generation of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
5255	4	2015johnpwells@gmail.com	N/A	The DEIS needs a much more thorough economic analysis of the benefits of restoring the Lower Snake River corridor. One-seventh or 140 river miles of the entire Snake River would be reclaimed by dam removal. This would provide and restore opportunities for fishing, hunting, rafting and general tourism which would add significantly to the economies of the area. The management plans of the federal agencies have proven numerous times to be significantly flawed over the last 25 years. A total of $18 billion federal dollars has been spent on recovery efforts since 1981, yet wild salmon and steelhead throughout the Columbia-Snake basin are still ESA listed.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the MOs, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The recreation analysis for the EIS considered the broad range of recreational activities supported by the region, including recreational fishing. While the analysis described any potential impacts to recreational fishing visitation, the EIS did not estimate these impacts separately from the overall impacts to recreation, or estimate changes in fishing visitation related to changes in fish abundance. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the Multiple Objective alternatives, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The commenters suggestion that $18 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at Federal Columbia River Power System (FCRPS) projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish). Bonneville uses its authority under 16 U.S.C. 839b(h)(10)(A), to make expenditures to implement its Fish and Wildlife Program. These expenditures provide systemwide funding for actions that also mitigate for the non-power purposes of the CRS, so Bonneville recoups the non-power share of those expenditures from the U.S. Treasury as credit, as required under 16 U.S.C. 839b(h)(10)(C).
5264	1	N/A	N/A	INACCURATE and MISLEADING INFORMATION In 2016, I attended the Court ordered CRSO scoping meeting held in Boise and was surprised to see charts labelled salmon and steelhead abundance is improving. The charts stated These graphs show the number of natural-origin adult fish returning to spawn. They represent the most complete data available on abundance for natural origin fish. The creators of these graphs had deliberately misled the public by selectively parsing out data from 1990-2015 and ignoring decades of data from 1957 to 1990. This was a focused effort to distort the truth and a seemingly unethical attempt to characterize fish status as being much better than the actual data clearly demonstrate.	The co-lead agencies take the responsibility to provide high quality information very seriously and disagree with the statement that any information has been used to deliberately mislead during any portion of this NEPA process. The intent of the graphs referenced that were presented at the scoping meetings were to show trends in wild fish populations since the 1990s when the stocks were listed under the Endangered Species Act. The intent was to focus on recent trends due to current dam operations combined with contemporary environmental variables. In 2016, the recent trends were generally positive for most stocks in the Columbia River Basin.
5264	2	N/A	N/A	It is disappointing (and surprising) that, in several locations, the EIS similarly presents inaccurate information in an apparent continuing effort to mislead the public: 1.) The Figure on pg. 3-300 distorts the truth and misleads the public by plotting combined salmon and steelhead return to Bonneville Dam from 1938-2019. To be accurate, this Figure needs to plot data by species and by wild and hatchery fish separately to avoid actual wild fish abundance from being hidden by hatchery fish.	Figure 3-111 on page 3-300 in the Draft EIS, is neither inaccurate nor misleading. The title is "Combined Annual Returns of Salmon and Steelhead to Bonneville Dam 1938-2019." The caption is: Figure 3-111. Combined Annual Salmon and Steelhead Returns (all species) to Bonneville dam from 1938-2019. These returns are a combination of hatchery and natural origin fish (data source: University of Washington-Data Access Real Time (DART) tool). This figure is part of the general overview of anadromous fish in the study area. The later sections of the EIS break out analyses and discussion by species and origin. The comment implies that hatchery fish are not relevant to the EIS. However, since ESA-listed salmonid species often include both naturally spawning and hatchery fish in the listing designation, many hatchery programs provide important benefits to ESA-listed species. In addition, hatchery origin fish are very important to Tribal and sport harvest within the Columbia River Basin, and are important supplementation to rebuilding natural populations.
5264	3	N/A	N/A	2.) The EIS contains misleading Figures and inaccurate statements about smolt survival, especially on pg. 3-302. Despite all the data to the contrary, the EIS continues to tout a per-dam survival metric. This metric is inaccurate for multiple reasons: it ignores delayed mortality, it ignores reservoir mortality, and it fails to illustrate that dam mortality is additive. In contrast to the touted >96% survival per dam, actual smolt survival from the Snake River to below Bonneville Dam averages about 50% (FPC 2019). For decades, the essential role of SARs in stock persistence and productivity has been clearly established and re-affirmed. In the 1960s, with four Federal Columbia River Power System (FCRPS) projects in place, SARs ranged from 3.5% to 6.5%	The metric "dam survival rate", is an empirical estimate (or modeled based on empirical data) of the survival rate of a specific group of fish from the immediate forebay through the structures and tailrace, or the inverse of the mortality rate induced by passing through the immediate forebay, structures, and tailrace. It is the most sensitive metric for assessing effects of operations and configuration of dams and therefore is frequently used. Dam survival rates were a key metric for the 2008 National Marine Fisheries Service Biological Opinion. When first mentioned at line 7247 on page 3-301 in the Draft EIS, the co-lead agencies have clearly stated that this metric does not include system or latent mortality. The next section discusses reach survival rates, which do include all mortality from passing the dams, the reservoirs and any other source in the system. By using total in-river survival, travel time, powerhouse passage rates,

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				(Raymond 1988; McCann et. al 2015, 2016). Dramatic changes have resulted from completion of all eight FCRPS projects. Water travel times from Lower Granite to Bonneville Dam, for example, increased from 2 days to a range of 40 days and an average of 19 days (Tuomikoski et al. 2009; Petrosky and Schaller 2010) and 76% of juvenile salmon that pass through the Columbia River hydro system died as a result of injury or stress incurred while migrating (Schaller et al. 2014). The PATH (Plan for Analyzing and Testing Hypotheses) process linked SARs to the probability of achieving NOAA interim survival and recovery standards in the 2000 FCRPS BIOP (Marmorek et al. 1998). The PATH analyses confirmed that a median SAR of 2% was necessary to achieve the 100-year interim survival standard for spring/summer Chinook salmon; a median 4% SAR was necessary to achieve the 48-year interim survival standard; and a median 6% SAR was necessary to achieve the 24-year interim survival standard (Marmorek et al. 1998). The Northwest Power Planning Council Fish and Wildlife Program (NPCC 2003, 2014) has consistently established an SAR goal with a 4% mean and range from 2%-6%. In 2018, the Independent Science advisory Board stated, SARs Objectives provide a readily measured, 1st-order objective for restoring stocks. Recent SARs for Snake River wild spring/summer Chinook salmon have averaged 0.7% above 8 dams in comparison to SARs for non-ESA listed wild spring Chinook salmon that have remained within the NPPC SAR objectives above fewer dams in the mid-Columbia River (McCann et al. 2019). From 2000-2017, wild Chinook salmon SARs averaged 3.6% in the John Day River above 3 dams, 2.5% in the Yakima River above 4 dams, and 0.7% in the Snake River above 8 dams (McCann et al. 2019). The John Day, Yakima, and Snake River populations experience the same treaty and non-treaty fisheries, pinniped predation, and ocean conditions; the primary differences among them are the number of dams they pass. A 4-fold increase in SARs will be necessary to meet survival standards and reduce extirpation risks for Snake River stocks. Eighty percent of the variation in salmon survival is explained by SARs (CSS 2017). Consequently, a more evidence-based approach is needed in the final EIS to evaluate each alternative and its ability to substantially improve SARs and meet the 4% SAR mean goal.	and Smolt-to-Adult return rates (SARs), the analysis done by the co-lead agencies is providing a full picture of the impacts to ESA-listed fish throughout their life cycle from the different approaches of operations, maintenance, and configuration captured in the alternatives. The SARs target of 4 percent and the range of 2 to 6 percent referenced in this comment refers to the Northwest Power and Conservation Councils (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the EIS analysis the Preferred Alternative will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative best meets all the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The agencies used current, high quality modeling information consistent with NEPA and did not rely on information contained in the Plan for Analyzing and Testing Hypotheses (PATH) Weight of Evidence Report (ESSA Technologies 1998), which is over twenty-years-old and does not reflect current CRS operations.
5264	4	N/A	N/A	3.) The statement on pg. 3-304 is very misleading: The adverse impact of past Columbia River System operations has been reduced over time, and multiple mitigation actions have improved habitat, hatchery operations, and predator management, thus increasing survival rates of individuals in these ESUs, reducing extinction risk, and thereby contributing to improvements in the likelihood of recovery. First, it implies that the likelihood of recovery is increasing, see Figure 1 above and the text describing the status of Central Idaho wild stocks to illustrate the continuing high risk of extinction for Snake River populations. Second, it implies that the actions taken over the past 30+ years have been effective. They have not, despite nearly $17 billion spent.	The co-lead agencies agree that more can and should be done to further improve the status of salmon and steelhead in the Columbia Basin. The co-lead agencies contribution to those additional efforts is reflected in the Preferred Alternative. The statement referenced on page 3-304 in the Draft EIS is accurate. The Preferred Alternative will continue progress and build off of the improvements of previous Federal efforts. The commenters suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at Federal Columbia River Power System projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96 percent and 93 percent for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30 percent. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
5264	5	N/A	N/A	Lack of a Full Suite of Alternatives: A full range of alternatives is needed, including an alternative that maximizes recovery of anadromous fish. The core of an effective EIS is the inclusion and evaluation of a Full Range of reasonable alternative, including a rigorous assessment of how well alternatives meet stated SAR goals.	The co-lead agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinions from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. While meeting the regional Smolt-to-Adult return rates (SARs) goals is a worthwhile endeavor, it is a recovery goal. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
5264	6	N/A	N/A	Inadequate Climate Assessment: I could find no quantitative discussion of the effect of climate change on Snake River salmon and steelhead. Climate effects are predicted to worsen and the EIS needs to more thoroughly describe potential climate effects for each alternative.	Regarding climate change, the climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at this time at the required resolution (river-scale vs global- or regional-scale). Therefore it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Sections 4.2.3 and 7.8).
5264	7	N/A	N/A	Inadequate Assessment of the Importance of Wild populations: Similarly, I could find no discussion of the importance of maintaining wild population abundances and their ability to maintain life history and genetic diversity. As described above, diverse wild populations provide the best opportunities for stocks to persist and adapt in an uncertain future. Each alternative should be evaluated to assess its ability to maintain wild stock diversity and adaptability.	Diversity is an important factor in an evolutionarily significant unit's (ESU) ability to persist and adapt, and is one of the factors considered in assessing an ESU's long term viability, along with abundance, productivity, and spatial structure. Analyzing all of these factors is appropriate for an Endangered Species Act (ESA) recovery analysis and is typically done by National Marine Fisheries Service in a Biological Opinion. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will continue to be led by National Marine Fisheries Service and the U.S. Fish and Wildlife Service and will to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies performed an appropriate level of analysis to assess the effects of operation and maintenance of the CRS on ESA-listed species. A full analysis of recovery is not required under either NEPA or the ESA.
5264	8	N/A	N/A	Vague EIS Goals: On pg. 2-3, Objective 1 is to: Improve ESA-listed anadromous salmonid juvenile fish rearing, passage, and survival within the CRSO project area through actions including but not limited to project configuration, flow management, spill operations, and water quality management. What exactly does this mean? As described above, Snake River stocks are a HIGH risk of extinction, including wild stocks in wilderness. A more rigorous and evidence-based goal is needed to achieve recovery. SARs, as described above, provide a rigorous and widely accepted goal within the basin. The EIS needs to re-state its goal to reflects recovery, not simply include something as vague as to improve.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region), increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
5264	9	N/A	N/A	Over Estimated Preferred Alternative Benefits: The Preferred Alternative (PA) fails to meet Court ordered mandates for recovery and will not improve the probability of persistence for ESA listed stocks. The stated benefits list an improvement of 35% and 28% for Chinook salmon and steelhead SARs, respectively. In truth, this is a relative benefit. However, even if that benefit were real, a 35% improvement for SARs averaging 0.7 % (see above) would ensure population declines because SARs would remain near or less than 1%. When SARs are below 1%, steep populations declines occur (ISAB 2018). Instead of recovering populations, the PA is more likely to result in continued population declines toward extinction. Of the alternatives evaluated in the Draft EIS, only MOA 3 (Multiple Objective Alternative 3) would result in an improvement in survival that would be sufficient to move toward recovery of Snake River salmon and steelhead. The CSS (Comparative Survival Study 2019) estimated a 2 to 3-fold increase in salmon abundance with the Natural River option and a 4-fold increase if Natural River is coupled with maximum spill over the Columbia River dams. SUMMARY Please correct the flaws listed above and more rigorously evaluate a full range of alternatives. Most importantly, please meet the Court ordered mandate and select a preferred alternative that will move past decades of ineffective actions and establish an evidence-based and effective path toward recovery.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies used high quality information in the EIS analysis. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2 percent (the lower end of the Northwest Power and Conservation Council's recovery targets for the region), increasing from 2.0 percent to 2.7 percent for Chinook, a 35 percent relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. Improving anadromous fish conditions were two of the eight objectives of the CRSO EIS. The agencies disagree, however, that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125 percent Total Dissolved Gas (TDG) at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For power and transmission, MO3 and Multiple Objective alternative 4 (MO4), individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5 percent of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125 percent and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
5281	1	N/A	N/A	Mitigation efforts on the Snake River system toward the protection of Salmon continue to fail. Numerous studies reflect that fish hatcheries present on the River are actually reducing the survival of Wild Fish. The failings occur as the larger hatchery smolts released into the system prey upon their smaller	Based on the fish analysis in Section 7.7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under this alternative, hatchery programs would continue as described under the No Action Alternative in Chapters 2 and 7, and a number of other mitigation measures would continue as well. The Preferred Alternative proposes measures such as increased spill

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				wild counterparts. Hatcheries also over time, dilute the genetics of Wild Fish resulting in marked degradation in their overall size. An example of this genetic interference is that the once mighty Snake River Chinook Salmon species historically that approached 100 pounds in size, is now after years of hatchery operations reduced returning fish to average in the 20 to 30 pound range.	intended to improve survival of anadromous salmonids. Figure 3-111 in the Draft EIS was an illustration that the CRS can and has supported large numbers of returning adult salmon and steelhead. As noted, this figure combines hatchery and wild fish. Over time, the Preferred Alternative is anticipated to benefit both wild and hatchery fish. Hatchery origin fish are very important to Tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS.
5281	2	N/A	N/A	This EIS makes little mention of the Endangered Southern Resident Orcas and minimizes the significance of Snake River Chinook Salmon as their prey. In doing so, this EIS draft ignores NOAA data on the diet of the SRKWs. The narrow scope of this EIS fails to account for the immeasurable cultural value, and economic benefits to the Pacific Northwest of protecting both Wild Snake River Salmon and The Southern Resident Orcas from Extinction. This EIS draft ignores the stark evidence that, as the 4 Lower Snake River Dams continue to block the River, significantly contributing to the lack of Wild Salmon available to the SRKWs such that, these dams are contributing in starving them toward extinction. This omission is a stark and critical failure of the bureaucracy to reconcile the obligations of the US Corps of Engineers, NOAA, and The Bonneville Power Administration under The Endangered Species Act and, once again sets these parties up for more costly litigation defending their self serving positions at the publics expense.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. The Preferred Alternative meets all eight objectives of the EIS and the purpose and need, including improving fish passage and survival for ESA listed fish. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5281	3	N/A	N/A	We must acknowledge that the primary purpose of these 4 dams was historically for the transportation of exports by barge and, it is important to note that now far less products are transported annually by barge than when the dams were built. The only reason barging remains the preferred option by farmers in the region shipping their wheat to market, over the rail option running directly beside the Snake River is that, the barging option continues to be heavily subsidized by rate hydro payers. The fact a newly upgraded rail line running beside the Snake River is not mentioned in this EIS, raises additional concerns around the objectivity of the draft report in this seemingly convenient omission of information that in effect downplays the viability of breach option for the 4 Lower Snake River Dams. The absence of this information raises flags of a perceived lack of accountability and bias by the bureaucracy responsible for producing the document.	Barging is not subsidized by rate hydro payers. Costs for construction and operations and maintenance are based on cost allocations for the projects. Costs for work on navigation features (navigation lock) is attributed to the navigation purpose. Costs for features serving multiple purposes are assigned to the purposes according to the approved cost allocation. The Great Northwest Railroad, owned by WATCO, is a short-line railroad that runs along the Snake River from Lewiston, ID to Ayer Junction, WA. Research completed for the EIS suggests that elevator to river port movements via short line rail are not currently occurring because in order for them to ship grain to river terminals on the Columbia River, they must operate on part of Union Pacific's rail line and WATCO's operating agreement with Union Pacific does not allow for these shipments. The effect of including this assumption and allowing movements on these short lines during a breach scenario would be to somewhat reduce the anticipated increases in shipping costs to shippers. A statement has been added to Section 3.10.3.5 to this effect, along with a reference to Appendix L that provides additional discussion of the impacts of modifying this assumption on quantified costs to shippers.
5281	4	N/A	N/A	We know the Lower 4 Snake River Dams produce nominal power for the grid and typically do so at times of year, when market demand is reduced. Arguments that these dams are crucial back up power for the grid fail to take into account and acknowledge the new technologies available in alternate green power options. In this there is also lack of objectivity in reconciling this with the significant costs of annually maintaining 4 obsolete dams.	The commenters statements are inconsistent with the findings in the EIS. Specifically, the four lower Snake River dams produce around 1,000 aMW of power, which is approximately 12 percent of the average power produced by the Federal Columbia River Power System (FCRPS). See Draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. This amount of lost power is equivalent to the amount of power used to serve 730,000 homes in the Northwest. See EIS, Section 3.7.3.5, Summary of Effect, page 9-935 in the Draft EIS, noting that generation from the four lower Snake River dams is approximately 90 percent of the power loss in MO3. While the regional power system does have surplus in some periods, most typically in the spring of high-water years, there are also periods when the region has very little or no surplus. For example during a winter cold snap demand for power may reach its annual peak. During a heat wave in summer when demand for power is high, river flows may be relatively low and several Federal and non-Federal hydropower projects are spilling water for juvenile fish passage. The EIS analysis for MO3, which includes a measure to breach the four lower Snake River dams, indicates that there is roughly a 14 percent chance of energy shortages in any given year (without factoring in the retirement of additional coal plants). See Section 3.7.3.5 of the Draft EIS, Table 3-165; Appendix J, Chapter 4 shows the seasonal variation of the loss-of-load probability (LOLP) events. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Draft EIS Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS.

					2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecast direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
5281	5	N/A	N/A	The cost of maintaining the 4 Lower Snake River Dams to the national economy is set conservatively at about $150million per year, yet clearly, these dams are largely responsible for the destruction of Wild Salmon runs which used to be seen way up into the Rocky Mountains of Idaho. If we remove the earthen berms around the Lower 4 Snake River Dams, Salmon and Steelhead would again have access to those areas and, their return would bring with them vitality and economic benefits to the region. Economic studies already completed for the region, warrant review and attachment to this EIS draft as they support significant benefits that would be realized to the Tri-Cities region once Snake River again runs free. In transitioning to breach the dams, rate payer funding already allocated to maintaining the 4 obsolete dams, could be used to support a smooth transition of the breach option. Farmers reliant on irrigation could be supported for associated costs of extending piping and pumping capacity from the returnees lower elevations of a free running Snake River.	The four lower Snake River dams do provide for fish passage. Breaching the dams would not give anadromous fish access to currently-blocked areas. Bonneville (or its ratepayers) does not have authority to fund the breach of dams under its statutory authorities. First, Congress granted Bonneville's discretionary direct funding authority (16 U.S.C. 839d-l) for Bonneville, the Corps, and Reclamation to proceed with funding additions, improvements, or replacements to the multiple purpose projects of the CRS without having to first wait for appropriations for the entire activity. Instead, Bonneville provides the power share directly so that the Corps and Reclamation need only seek appropriations to cover the non-power share; that is, the share attributed to the non-power purposes of the dam. Stated another way, Bonneville can provide direct funding to cover only hydropower costs, whereas costs attributable to or shared by other purposes of the dams would be joint projects and would require congressional appropriations to cover the non-hydropower share of the cost. The breach of a dam is not an addition, improvement, or replacement of a dams power features, so the direct funding authority does not apply to the breach of a dam. And, even if Bonneville could provide funding for breach, it could provide no more than the power share of the cost of breaching. Congress would still have to provide appropriations to the Corps for the non-power share. The use of Bonneville's discretionary direct funding authority therefore cannot provide a means of funding the breach of dams absent an act of Congress. Second, Bonneville cannot use its authority under the Northwest Power Act section 4(h)(10)(A) (16 U.S.C. 839(b)(h)(10)(A)) to fund dam breach. The Bonneville Administrator must use the Bonneville Fund to protect, mitigate, and enhance fish and wildlife affected by the operation and development of the Federal Columbia River Power System in a manner consistent with the Northwest Power and Conservation Councils (Council) Fish and Wildlife Program, the Councils Power Plan, and the purposes of the Act. Currently, dam breaching is not part of the current Council Fish and Wildlife Program, the Seventh Power Plan, or evident within the purposes of Act. For example, dam breaching is inconsistent with the statutory purpose of Section 2(6) of the Act, which says in relevant part that anadromous fish are dependent on environmental conditions substantially obtainable from operations and management of the Columbia River System and other hydropower facilities in the basin. Additionally, as demonstrated in Section 3.7 (Power Generation and Transmission) of the EIS demonstrates, dam breaching is also inconsistent with another purpose of the Northwest Power Act, Section 2(2), which provides for assuring the Pacific Northwest an adequate, efficient, economical, and reliable power supply. Section 4(h)(10)(A) therefore does not mandate or confer authority on the Administrator to fund the dam breach. The costs to operate and maintain as well as provide capital investments for the lower Snake River dams are described in Appendix Q, Tables 4-1 and 5-1. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170, Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class2/ is forecast to have a 50-year levelized cost of generation3/ of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecast direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide mitigation for the effects to private infrastructure such as irrigation pumps, wells, or private docks. However, private and public entities could extend intake pumps, groundwater wells, or other infrastructure. MO3 was not identified as the Preferred Alternative in the Draft EIS.
5339	1	N/A	N/A	For a plan of this scope and magnitude that effects huge numbers of citizens it is beyond unfortunate that such a minimal open comment period was offered. That is not transparency in government. Several of my friends were not aware of this DEIS and the short time frame to comment. If the intent was to fly under the radar it was wildly successful.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
5379	1	smitchel@alscott.com	N/A	attachment below	Unfortunately, an attachment was not received from the commenter. The co-lead agencies requested the commenter resubmit via e-mail on June 25, 2020; however, the co-lead agencies did not receive a response to this request.
5384	1	bjohnstone1@cableone.net	N/A	MO3 needs an accurate cost-benefits analysis of the four lower Snake river dams and the actual power they generate not the design generation capabilities. 8-9 months of the year these dams are not capable of meeting anywhere near design capabilities due to lack of water flow in the river itself. Turbine and generator maintenance cost will be in the 10s of millions of dollars per year. The MO needs a more thorough and realistic economics analysis on the benefits of a restored lower Snake River corridor. Fishing, hunting, rafting and general tourism need to be considered using a actual model.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. While a cost-benefit analysis was not performed, the EIS analysis included a thorough analysis of quantifiable impacts of each Multiple Objective alternative, including impacts on power generation. For MO3, the costs of replacing the lost generating capability of the four lower Snake River dams is discussed in Section 3.7.3.5, Lower Snake River Replacement, page 3-905 in the Draft EIS. The rate impacts of these replacement resources, which includes cost savings from breaching the four lower Snake River dams, is described in Section 3.7.3.5, Table 3-166, page 3-920-924 in the Draft EIS. As described in the EIS, even with the cost savings associated with reductions in dam operating and fish and wildlife mitigation costs, the net impact on power rates is in the range of between 13-50 percent (for zero carbon resources replacements) and 4-10 percent (for natural gas/least cost replacements). The comment is also correct that the four lower Snake River projects do not operate at full capacity all year. However, this is the case for most resources. Very few hydropower projects or other resources, including natural gas, wind, and solar, operate at their designated name-plate capacity for most of any year. On average, these projects produce power year-round, including during times of peak demand. For example, using average water conditions, and an 80-year water data, the four lower Snake River dams produce between 460 aMW to upwards of 1,400 aMW of power during the winter months of December through February, which are typically the most energy intensive months for Bonneville. See EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159 in the Draft EIS. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170, Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/Levelized Cost of Generation is defined as the forecast direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes directed funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville system-wide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
5416	1	N/A	N/A	Removal of the four lower Snake River dams would also limit the regions ability to meet its clean energy goals. The four dams combined generate more than 1,000 average megawatts of affordable, carbon-free electricity. They allow us the flexibility to safely integrate other renewables such as wind and solar into the grid. We need these resources to build upon as we work toward a clean, renewable energy future.	The information provided in the comment regarding greenhouse gas emissions and the integration of renewables is consistent with the findings of the EIS. See Draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
5416	2	N/A	N/A	Reliable service is also critical to the success of our local economy. When a pear is picked from a tree in the fall, that pear must be transported to a controlled atmosphere environment and cooled from the ambient temperature of perhaps 90 degrees to 30 degrees in 24 hours or less in order to maintain peak quality and marketability through next several months. According to the DEIS, the loss of the lower Snake River dams would double the regions risk of blackouts. A blackout during harvest could result in financial ruin for the fruit producers in our service territory and throughout the region.	The comments that breaching the four lower Snake River dams would increase the frequency of power shortages unless replacement resources were built and could have adverse socioeconomic effects are consistent with EIS findings. See Draft EIS, Section 3.7.3.5, page 3-903. The co-lead agencies did not include the measure to breach the four lower Snake River dams, which was evaluated in MO3, in the Preferred Alternative identified in the Draft EIS.
5443	1	beverlynichols58@yahoo.com	N/A	Within the United States, the Columbia-Snake River watershed is the most important source of salmon for the endangered Puget Sound orcas. In its 2008 Recovery Plan for Southern Resident Killer Whales, NOAA Fisheries underscored the importance of this watershed to the orcas, stating that, [p]erhaps the single greatest change in food availability for resident killer whales since the late 1800s has been the decline of salmon from the Columbia River basin. The endangered orcas forage in the coastal waters of the Northeast Pacific Ocean more than half the year. According to satellite tags, the orcas travels often center around the mouth of the Columbia River when Snake River Chinook are returning to the Columbia. The births of eight surviving orca calves between December 2014 and January 2016 coincided with larger Snake River hatchery salmon runs that occurred in 2013 through 2015, in association with a hatchery research project that greatly inflated the runs. Although the research project has ended, it provides good evidence that when there are plentiful Snake River Chinook, the endangered orcas can conceive, reproduce, survive and recover. Breaching the dams would be the single measure most likely to recover abundant salmon and steelhead in time to enable the endangered Puget Sound orcas to survive.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The determination for SRKW in regards to MO3 was based on the following facts: The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
5443	2	beverlynichols58@yahoo.com	N/A	The recent Ninth Circuit decision in United States v. Washington, No. 13-35474, 2016 U.S. App. LEXIS 11709 (9th Cir. June 27, 2016), held that both Washington State and the United States governments are liable to signatory tribes for blocking or impeding salmon migration in violation of the 1855 Stevens Treaties. This exposes the United States and potentially Washington State to huge damages liability to the tribes, if the dams continue to be maintained. This liability can be cut off by breaching the dams this year.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. Treaty specific information is included in Section 3.17 as well as Chapter 7. The co-lead agencies recognize and respect the legal obligations imposed by treaties. The co-lead agencies accordingly included Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration of decision making. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. The cultural significance and impacts of salmon and steelhead fisheries are described in the Ceremonial and Subsistence Fisheries sub-section and the Social Importance of Commercial, Ceremonial and Subsistence Fisheries sub-section of Section 3.15.2.1. Fisheries tribal interests are provided in Section 3.15.4 additional details regarding the economic significance of salmon and steelhead fisheries have been added to the recreation analysis (Section 3.11) including tribal interests (Section 3.11.3.7). Treaty rights are discussed in the Executive Summary, Section 3.16 Cultural Resources, and Section 3.17 Indian Trust Assets, Tribal Perspectives, and Tribal Interests. Appendix P includes copies of tribal perspectives that were submitted by tribes. Tribal consultation is described in Sections 1.5, 3.5, and 3.15; and Chapter 9. Most sub-sections within Chapter 3 include a Tribal Interests section at the end of the sub-section that attempts to summarize tribal issues by topic. Currently, fish ladders are proven effective at moving adult fish upstream at the dams that have them. In terms of bypassing fish upstream, the current configurations of the CRS dams that have fish ladders already have effective upstream adult passage. The 4 lower Snake and 4 lower Columbia River dams also have systems for bypassing fish around turbines and powerhouses. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
5447	1	ttidwell1@hotmail.com	N/A	The Executive Summary and the DEIS are misleading when they over emphasize the consequences of power generation reduction with alternative MO3, breaching the 4 lower Snake River (LSR) dams. These dams produce only 4-5% of FCRPS average power generation and produce less power than BPA currently exports to other regions. The secondary power generation from the other dams easily replaces the power generation from the lower Snake River dams. Given there maybe a few days of peak power use in the winter and summer when the LSR dams add system capacity, but this can be provided by other resources. The DEIS does reference that the loss of power generation with MO3 could be replaced through conservation, solar, wind,	The comment suggests that the regional supply of power is sufficient without the output of the four lower Snake River dams, and even sufficient without replacing the output of the four lower Snake River dams with other resources. The comment reaches this conclusion by comparing the average resource output for the remaining regional resources (without the four lower Snake River dams) with average load in the region. Such an approach, however, only demonstrates that on average that is under average conditions - all power system needs would be met. This approach does not address conditions other than average. That is, regional demands for power would not be met at times of greater than average load or lower than average resource output. In those instances, power system emergencies or blackouts would occur. The EIS uses a more robust measure of power system reliability and resilience than the average MWs approach suggested by the commenter. Specifically, the EIS uses the loss-of-load probability (LOLP) metric utilized by the Northwest Power and Conservation Council. See draft EIS, Section 3.7.2.2; Appendix H Power and Transmission, at Section 2.1; Appendix I Hydroregulation, Section 2.4.4. The LOLP metric evaluates the adequacy of the power supply in the region to meet firm power

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				and batteries. In addition the DEIS does not show the potential for increased power generation from more efficient turbines or increasing the average capacity at CRS dams.	needs under various conditions. It is measured in terms of a percentage, and represents the likelihood of a year having one or more blackouts. See Appendix H Power and Transmission, at Section 2.1 in the draft EIS. The current LOLP under the No Action Alternative is 6.6 percent; this is equivalent to a year with one or more blackouts in every 15 years. The EIS uses this LOLP level as the benchmark from which to gauge the other MOs. Under Multiple Objective (MO) Alternative 3, on average, the region has surplus generation leading to export sales during certain periods and water years. Nevertheless, to maintain regional reliability at the LOLP levels of the No Action Alternative, replacement resources would be needed. This is driven by the timing and magnitude of changes in hydropower generation analyzed in the EIS. As shown by the analysis of the LOLP, in some years and times of the year, particularly winter and later in the summer of drier years, without the four lower Snake River dams there would be insufficient power supply in the region leading to power emergencies and blackouts. Specifically, without replacing the power from the four lower Snake River dams, the LOLP of the region would more than double to 14 percent, which is equivalent to one or more blackouts every seven years. See Section 3.7, page 3-903 and Appendix H-Power and Transmission, at Table 2-1 in the draft EIS. The commenter also presumes that the power produced from the four lower Snake River dams is surplus and exported out of the region. The power output for the four lower Snake River dams are not exclusively sold as surplus as the commenter suggests. Bonneville sells power from the Federal Columbia River Power System (FCRPS) as a unified system, not from specific projects. In this regard, the power generated from the four lower Snake River dams are pooled with all other FCRPS power sold by Bonneville to meet Bonneville's collective power obligations. Most of this power is used to meet the loads of regional publicly owned utilities, such as municipalities, rural utilities, and public utility districts under long-term power-sales contracts (see Section 3.7.2.5 Bonneville Power and Transmission Customers in the draft EIS). A small portion of power is sold in the California energy market, but these sales are not from specific projects, but rather from the collective FCRPS. Finally, the references to a regional surplus does not take into account the accelerated loss of coal from the region in coming years. The EIS relied on existing coal retirements for its analysis. See draft EIS, Section 3.7.3.5, at page 3-841 and Appendix H, Section 2.3. As discussed in these parts of the EIS, with accelerated coal retirements, the region would likely experience a significant regional deficit of power, which would require adding additional power resources to maintain power system reliability at the No Action Alternative levels. See draft EIS Sections 3.7.3.3 through 3.7.3.6 and in Section 3.7.3.5, Potential Replacement Resources and Associated Costs; see also Section 3.7.3.2, Table 3-12. The No Action Alternative incorporates turbine upgrades at McNary dam and Ice Harbor dam. Therefore, these increases in efficiency are already included in the evaluation of the current reliability. (See draft EIS Section 2.4.2.1.) The action alternatives, including the Preferred Alternative, include planned turbine upgrades at John Day Dam, as discussed in the draft EIS in Sections 2.4.3.1, 2.4.4.1, 2.4.5.1, 2.4.6.1, and 7.6.2.15.
5447	2	ttidwell1@hotmail.com	N/A	The DEIS does describe in detail the less cost and GHG consequences of replacing the loss of power generation with fossil fuel production (coal and natural gas) which would lead the public to think that this is the only option. This is contrary to what is happening in the west with more renewable energy on the market and more being developed. One example is all new housing construction in California is required to have solar panels. The DEIS quantifies by acreage the number of solar panels needed to replace both the primary and secondary power generation of the 4 LSR dams, but the final EIS needs to display the annual increase in renewable power generation that has been occurring and projections for the future especially if there is an increase in market. According to an article in the New York Times, in 2019 solar capacity increased 23% from the year before and is projected to increase by another 19% this year. In several western states wind turbines and solar panels now produce electricity at a lower cost than natural gas and coal. Over the next 5 years total solar capacity will more than double (SEIA).	The EIS acknowledges the increase in renewable power generation occurring in the region in Section 3.7.2.1, Power Generation (see Figure 3-160 in the draft EIS). The EIS also uses the best available resource information from the Northwest Power and Conservation Councils, 7th Power Plan and Mid-term Update to evaluate potential replacement resources. The basis for developing both of these portfolios may be found in Section 3.7.3.1, Methodology, and Section 3.7.3.5, Potential Replacement Resources and Associated Costs for Multiple Objective Alternative 3, specifically. In addition, regarding the potential increase in renewable power generation, the EIS presents the increased solar generation from the replacement portfolios. See Table 5-16 in Section 5.2.1 of Appendix H in the draft EIS. As described in Section 3.7.3.1, Availability of Coal Resources (page 3-841 in the draft EIS) and Section 3.7.3.2, Effects on Power System Reliability (pages 3-845-847 in the draft EIS), the region is retiring the majority of coal-fired generation, and it is likely that the region could develop considerable quantities of solar generation to replace the coal generation. Based on responses to public comments, the final EIS contains an expanded description of how the potential replacement resource portfolios were selected for the EIS. (See Section 3.7.3.1 in the draft EIS).
5447	3	ttidwell1@hotmail.com	N/A	The DEIS indicates the cost of electricity with alternative MO3 will increase which is misleading. Especially after 2028 when firm power sales contracts expire and preference customers will have a choice to purchase power from other power suppliers. As stated in the DEIS the average spot market price for power has steadily declined due to the abundance of low-cost natural gas and large-scale development of variable renewable energy resources, such as wind and solar. There is nothing in the law that directs BPA to maximize power generation and BPA currently over produces power generation and then sells secondary power at a significant discount. The final EIS needs to display the price for secondary power compared to what their find and preference customers pay.	Chapter 4.1 of Appendix H presents both the average market prices and Bonneville wholesale power rates for all alternatives. The surplus power price is below that of Bonneville's wholesale power rates, but the comment incorrectly suggests that: (a) the wholesale spot-market price for power is equivalent to the firm power provided under Bonneville's long-term power sales contracts; and, (b) that customers could purchase all their power from the spot market. The spot market price is for wholesale market energy purchases for surplus energy. It does not ensure availability nor deliverability, and is not suitable for load service, i.e., service to a load in any amount at all times. It is suitable only for buying and selling around firm load and resource forecast error, and for reducing system and fuel costs where and when more optimal and lower cost dispatch of energy resources is possible. The spot market does not always have power available. Bonneville's long-term power sales are sold at a rate that is designed for firm load service; it ensures that what is needed is provided regardless of weather, hydrologic conditions, load, wind, market depth, or solar variability. See Section 3.7.2.7, Power Rate Determination, for additional details. The commenter is correct that preference customers will have a choice in 2028 to purchase power from Bonneville or from other sources. See Section 3.7.2.5, at pages 3-801-02 in the Draft EIS; Section 3.7.3.1, at pages 3-842-43 in the Draft EIS. This option is captured in Section 3.7.3.1, Financing Portfolios, page 3-815 in the Draft EIS. Whether Bonneville acquires new resources or customers acquire new resources themselves, the end-user rates will increase to cover this cost. For Multiple Objective 3, Section 3.7.3.5, Table 3-172 in the Draft EIS shows the effect on retail rates for these options, and Table 3-176 in the Draft EIS shows the impact on commercial and industrial customers. Finally, to maintain regional reliability at the No Action Alternative levels, replacement resources would be needed under Multiple Objective 3 (MO3). The cost of replacing the capability of the four lower Snake River dams is described in detail in the Draft EIS in Section 3.7.3.5, Potential Replacement Resources and Associated Costs. The Draft EIS takes into account the cost savings from the breaching of the four lower Snake River dams. Even with these savings, base rates paid by customers of Bonneville (local public and community owned utilities) would likely increase. Using natural gas as the replacement resource (the least-cost resource portfolio) Bonneville's wholesale power rates could increase 4 percent to 10 percent. See Table 3-166 in the Draft EIS. Using zero-carbon resources to replace lost capability from the four lower Snake River dams capability, Bonneville's wholesale power rate could increase 13 percent to 50 percent. See Table 3-166 in the Draft EIS.
5447	4	ttidwell1@hotmail.com	N/A	With river navigation, the DEIS states that downriver tonnage on the Columbia River has increased but on the Snake River it has decreased. In 2018 less than 6% of downriver tonnage passed through the locks on the lower Snake River dams with over 94% entering below Ice Harbor Dam and on the Columbia River. The DEIS overestimates that the cost of transportation of agriculture products will increase with the breaching of the 4 LSR dams. According to the DEIS there has been a 47-50% reduction in downriver wheat and barley tonnage on the LSR and no indication that it will increase. Construction of shuttle rail facilities in the Palouse is just one example of how the market and designation of product determines the mode of transportation. By using examples that transportation costs will increase with the breaching of the 4 LSR dams is misleading since the data indicates that less tonnage is being transported on the lower Snake River which indicates that truck and/or rail is a viable transportation option. Also I did not find in the DEIS that commercial river navigation does not pay for the locks O&M costs and the necessary dredging. This cost is covered by the public through Congressional appropriations. In the final EIS, this cost should be displayed to show the true cost comparison of river transportation versus land transportation.	Access to barge transportation is the most cost effective means of accessing export markets for many of grain producers in the Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS shows. It is true however, that barge movements on the Snake/Columbia river have declined over the past 20 years, but it also appears that the decline has stabilized over the past 10 years. The commenter is correct that the lower Columbia River volumes have increased downriver from Portland, Oregon due to the expansion of export terminals that ship soybeans/corn coming from the Midwest U.S. The EIS provides the history of volumes moving down the Snake River in Section 3.10. Cost analysis results for alternatives and associated system operations are described in Section 3.18. Appendix Q provides additional details regarding O&M costs, including dredging.
5447	5	ttidwell1@hotmail.com	N/A	With alternative MO3 there will be economic impacts to some ongoing river activities. Definitely the cruise boats operating on the Snake River will have to change their operation. However the DEIS just shares information on current operations and does not use economic data that would offset the economic losses. The final EIS needs to display the potential for different recreation opportunities that would occur with a free flowing river and still have the cruise boats operating on the Columbia River.	Cruise ship visitation is characterized in Section 3.10, including a description of its economic contribution to the region. Section 3.10.3.5 describes the contribution of cruise ships as supporting approximately 230 jobs in the region, $6.2 million in labor income, and $17.8 million in annual output (sales). Impacts on the industry are described in Section 3.10.3.5. Under MO3, it is assumed that cruise boats would no longer be able to operate on the lower Snake River. River recreation that would occur post dam breach in the long-term under MO3 is described in Section 3.11.3.5.
5447	6	ttidwell1@hotmail.com	N/A	As I stated before, the navigation economics uses data that is no longer relevant and needs to use current information to show the economic impact to river transportation. According to the DEIS downriver tonnage of wheat and barley through the locks on the LSR dams has decreased from 4.8 million tons to the low of 2.4-2.7 million tons annually. The vast majority of the annual 67 million tons of downriver tonnage occurs below Ice Harbor Dam on the Columbia River. The lower Snake River only supports 5-6%. And again the final EIS needs to include the cost of O&M for locks and dredging when discussing the economics of river navigation.	Access to barge transportation is the most cost effective means of accessing export markets for many grain producers in the Pacific Northwest currently and removing that option will increase transportation costs for grain producers, as the EIS shows. It is true however, that barge movements on the Snake/Columbia river have declined over the past 20 years, but it also appears that the decline has stabilized over the past 10 years. For evaluating effects, 2.4 million tons is used, which reflects the average over the past 10 years. The forecast of tonnage on the lower Snake River is 2.4 million tons, as described in Section 3.10.3.5. Cost analysis results for alternatives and associated system operations are described in Section 3.18. Appendix Q provides additional details regarding O&M costs, including dredging.
5447	7	ttidwell1@hotmail.com	N/A	With irrigation benefits from the lower Snake River dams the DEIS states that the water table will drop and modifying existing pump systems is cost prohibitive. I question this statement where upgrading the surface and groundwater infrastructure can be done with one estimate of $200 million.	In Region C (lower Snake River), and potentially Region D (mainstem Columbia River) around the confluence of the lower Snake River, MO3 alternative, which includes breaching the earthen embankment of the four lower Snake River dams, would have adverse effects to farmers and irrigation. Currently and in the No Action Alternative, water is available from the pools of these facilities and from groundwater that results from the pools. Removing the earthen embankment portion of the dams will reduce pool elevations by up to 100 feet, which would make surface pumps inoperable. Groundwater pumps in the wells may also be affected due to decreased groundwater elevations depending on the connectivity of the aquifer to the pools. Municipal and industrial water pumps in the Lewiston area would also likely be adversely effected. The analysis in the EIS estimates a range of $132,145,280 to $205,656,518 for municipal and industrial (not including irrigation) water supply modification construction costs for pumps and wells. Private or public entities or businesses could take actions and/or build infrastructure to extend pumps or water supply access for water. The Corps (2002b) report analyzed dam breaching and its effect on water supply. This analysis considered several system modifications that would allow for the continuation of water deliveries to existing farmlands. The report concluded that modifying the existing pump system was cost prohibitive. See Chapter 3 analyzes the social and economic effects of implementing a dam breaching alternative (MO3) and Chapter 5 for mitigation discussion.
5447	8	ttidwell1@hotmail.com	N/A	The final EIS also needs to display the increase in costs to the public when interest on BPA debt increases and also what happens if interest rates increase. The public needs to be aware that BPA loses millions of dollars each year with the operation of dams that are not economically viable. The final EIS needs to clearly state that the operation of the 4 LSR dams results in a net annual loss of $71 million to BPA. The final EIS needs to document the economic impact of both past and future land management activities on both public and private land to help mitigate the dam impacts to anadromous fish. Yes, BPA has provided funding to offset some costs of structures and habitat improvement, but here is no compensation to land owners or the public for actions that have been implemented to prevent the loss of anadromous fisheries especially in Washington, Oregon, Idaho and Montana. The economic impacts include but not limited to impact on ranching and farming operations, costs to maintain forest resiliency, impacts to recreation and O & G businesses, impacts to communities that depend on anadromous fisheries as a main economic activity and also the loss to the public with the reduction in opportunities to fish and now with the high likelihood of eliminating the viability of wild anadromous fish in Idaho.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries that would occur under a dam breach scenario as major and beneficial, although quantitative impacts from fish modeling results are limited. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $156 million

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					and $417 million and the benefit-cost ratios are between 2.9 and 6.1. If the generation could be reliably replaced with short-term wholesale market purchases (see Table 3-170 of the Draft EIS), the lower bound for net benefits would fall to $57 million and the benefit-cost ratio would fall to 1.7. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation <Blockedhttps://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf> at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: Blockedhttps://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf <Blockedhttps://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf> and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecasted direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
5447	9	ttidwell1@hotmail.com	N/A	In the section of the DEIS addressing climate change I appreciate that the current science is shared that shows how the climate is warming and will only increase in the near future. The DEIS also indicates how climate change will affect stream flow, amount and timing of spring runoff, and snow pack. But the final EIS also needs to emphasize that fish access to the cold water habitat provided in the Snake River drainage is essential to maintain the viability of wild anadromous fisheries.	The scope of the EIS includes areas affected by the operations and configuration of the CRS projects; the comment is not clear as to what portion of the Snake River drainage is the subject of the comment. The Snake River basin upstream of the Lower Snake River projects is currently accessible to anadromous fish via fish ladders on these projects, and the effects to fish from each of the alternatives is analyzed in Chapter 3 of the Draft EIS. The Snake River drainage above the Hells Canyon Complex is outside of the scope of this EIS as the co-lead agencies do not have jurisdiction over these projects.
5447	10	ttidwell1@hotmail.com	N/A	The DEIS is very clear that with the preferred alternative, unless there is a significant reduction in latent mortality, which the DEIS provides no assurances, we will continue to see a reduction in SAR. We are on the cusp where it will only take a few years with low SAR and we could lose the wild anadromous fisheries in the Snake drainage. The DEIS states that BPA is not responsible for the recovery of threatened and endangered fish species. BPA is required by law to not likely jeopardize the continued existence of any threatened or endangered species, but BPA is also responsible for recovery of the anadromous species to ensure viability.	Based on our analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. In compliance with ESA, the co-lead agencies submitted biological assessments to NMFS and USFWS (Appendix V). In this Final EIS, the Biological Opinions from NMFS and USFWS can be found in Appendix V, completing ESA consultation on the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return (SAR) rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
5447	11	ttidwell1@hotmail.com	N/A	The final EIS needs to fully display the benefits of MO3, present the beneficial economics and provide reasonable estimates of what it will take to mitigate effects to river transportation, irrigation, and a reduction in secondary power production. The final EIS should include the economic analysis from the ECONorthwest study on the Lower Snake River Dams Economic Tradeoffs of Removal.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in the Snake River and tributaries as major and beneficial. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. As described in Chapter 5 Mitigation, specific regulations guide the development of appropriate mitigation measures to address environmental impacts. If in a future analysis, breaching were to be selected as the Preferred Alternative, further, more detailed evaluations and NEPA would be needed along with congressional authorization and appropriations to assess the engineering requirements of the project and to potentially further refine and develop mitigation measures. However, it should be noted that as described in Section 5.1.1., Overview of Mitigation, mitigation measures developed as part of a NEPA process are not intended to indicate the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures described. But rather provide a list of potential mitigation needs, some of which could be implemented by other agencies, officials and/or the public who would potentially benefit from the mitigation measures. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. The ECONorthwest analysis and the EIS employ different analytical frameworks and rely on different findings with respect to the outcomes of breaching the four lower Snake River dams. First, the ECONorthwest report applies a cost-benefit analysis framework, emphasizing monetization of all categories of impacts. Consistent with NEPA analysis frameworks, the EIS expresses beneficial and adverse effects across a variety of qualitative and quantitative environmental and economic metrics. That the effects of the alternatives on fish are not quantified as monetized economic values does not mean that they were not considered in the context of the analysis. Second, the findings of the ECONorthwest report that the benefits outweigh the costs of breaching the dams rely on the implicit assumption that breaching would result in restoration of salmon populations. The fish effects analysis in Section 3.5 of the EIS does not find that Multiple Objective alternative 3 would result in recovery of salmon or steelhead populations or in restoring the populations to historical levels. Thus, the values presented in the ECONorthwest report should not be considered as representative of the benefits of MO3.
