1.2.3 Comments and Response Table

The co-lead agencies reviewed and considered all submissions received during the public comment period. Table 1-2 contains all substantive comments received in those submissions with a response from the co-lead agencies. Submissions that expressed statements of support or opposition; made general statements without requests for information; did not request a change in the EIS; or commented on topics outside the scope of the CRSO analysis are not included in Table 1-2. A general response to these type of comments can be found in Chapter 9 of the Final EIS.

It should be noted that a single submission can contain both substantive and non-substantive comments within the text. The co-lead agencies reviewed all submissions and identified the substantive comments within these submissions.

Form letter substantive comments and responses are addressed in Section 1.2.4.

Table 1-2 is sorted by letter number, then comment number. To find a specific substantive comment, reference the letter number associated with commenter in Table 1-1 above, or search by name, email, or affiliation. Comment text is presented as submitted which can include spelling errors. This text has not been edited.

Table 1-2. Table of Comments Received and Co-Lead Agency Response (1/ References cited in responses can be found in the Final EIS Chapter 11, References)

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response1/
14	1	tcuezze@gmail.com	N/A	While the Corps, USBR, and BPA (agencies) have made many efforts to reduce salmon mortality, including fish ladders and cold-water releases, these have had only minuscule effects on salmon. The 4 dams on the lower Snake River block access to critical salmon spawning habitat on Idaho's Salmon River and on numerous smaller tributaries. Dam removal is empirically the most effective technique to aid salmon recovery, as demonstrated by the remarkable success of the removal of Elwha and Glines Canyon dams on the Olympic Peninsula. The Preferred Alternative continues a 50 year track record of failure to prevent salmon mortality. Even if salmon survival rates in transiting the dams were 100%, the Preferred Alternative does nothing to address the problem young smolt face in transiting large, slow moving reservoirs rather than fast-flowing rivers.The energy expenditure of transiting the 8 reservoirs on the Snake and Columbia rivers between the Salmon River and the ocean leave salmon unprepared to face the rigor of saltwater and cause high mortality rates. Only MO3 can truly address salmon recovery.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on our analysis in the Fish resources section of Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery as compared to the No Action. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and effect on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The effects of removal of the Elwha Dam and the effects of breach of lower Snake River dams are in not comparable. Elwha Dam had a nameplate capacity of just under 15 MW. Its annual power production pales in comparison to the 1,100 aMW provided by the lower Snake River dams. Also, Elwha Dam did not have fish passage. The four Snake River dams do. Removal of the Elwha dam allowed the Elwha River to flow freely. Even if the four Snake River dams were removed, the Snake River would still have regulated flows due to the dams located upstream.
14	2	tcuezze@gmail.com	N/A	The Agencies present numerous negative effects to MO3 while excluding its many positive impacts. Chief among these is the issue of power generation. In the Draft EIS, the Agencies downplay the fact that power from the dams on the lower Snake River is not sold to contracted customers of the BPA but is surplus which is sold to customers outside the BPA service area to subsidize BPA power. Most of the power from the lower Snake River dams is sold to California, where electricity prices have dropped due to increasing use of renewables. Eliminating the power generation from the Snake River dams would not create a need for more power production in the Pacific Northwest, and would still leave the BPA with a large surplus of power. The main area affected would be California, where renewable energy is increasingly cheap and plentiful. The Agencies also claim that base power from the dams is key to serve as baseline power generation as the grid switches to renewables like wind and solar. However, the Pacific Northwest already has a large-enough surplus of hydropower, nuclear, natural gas, and other constant-output energy sources to meet this baseline demand. While population is expected to increase, these increases will be countered with more efficient energy technology. Only very rarely is Snake River dam energy used to meet load requirements, and multiple analyses have shown that the cost to cover these small requirements with new facilities will be much lower than the cost to mitigate negative effects on salmon. Additionally, because these are run-of-the-river dams with relatively little energy storage capacity, they do not provide consist levels of energy production and therefore are not as reliable as sources of baseline power.	The power output for the four lower Snake River dams are not directly sold to California entities nor is their output sold exclusively as surplus as the commenter suggests. Bonneville sells power from the Federal Columbia River Power System (FCRPS) as a unified system, not from specific projects. In this regard, the power generated from the four lower Snake River dams are pooled with all other FCRPS power sold by Bonneville to meet Bonneville's collective power obligations. Most of this power is used to meet the loads of regional publicly owned utilities, such as municipalities, rural utilities, and public utility districts under long-term power-sales contracts (see Draft EIS Section 3.7.2.5 Bonneville Power and Transmission Customers). A small portion of power is sold in the California energy market, but these sales are not from specific projects, but rather from the collective FCRPS. As explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, breaching the four lower Snake River dams would have a direct and substantial effect on the supply of Federal power to meet regional load requirements. These effects would impact both actual energy to meet regional load requirements and generating capacity (peaking capacity) to meet variability in loads. The four lower Snake River dams are among the most valuable projects in FCRPS. These dams provide over 1,000 MW of carbon-free energy and up to 2,000 MW of sustained peaking capacity at certain times of the year. The dams also have unparalleled ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,200 MW of capability in certain months of the year. To maintain regional reliability at the No Action Alternative levels, replacement resources would be needed. The cost of replacing the capability of the four lower Snake River dams is described in detail in the Draft EIS in Section 3.7.3.5, Potential Replacement Resources and Associated Costs. The Draft EIS takes into account the cost savings from the breaching of the four lower Snake River dams. Even with these savings, base rates paid by customers of Bonneville (local public and community owned utilities) would likely increase. Using natural gas as the replacement resource (the least-cost resource portfolio) Bonneville's wholesale power rates could increase 4 percent to 10 percent. See Table 3-166 in the Draft EIS. Using zero-carbon resources to replace lost capability from the four lower Snake River dams capability, Bonneville's wholesale power rate could increase 13 percent to 50 percent. See Table 3-166 in the Draft EIS. While the four lower Snake River dams are indeed run-of-river projects, there is flow in the lower Snake River year-round. Further, upstream storage projects (Dworshak and Brownlee), regulate some of the water flowing into the lower Snake River. In particular, the lower Snake River projects produce a significant amount of power in the winter, which is currently the region's highest demand period.
14	3	tcuezze@gmail.com	N/A	Next, the Agencies say that the loss of barge transportation capability provided by the dams will cause increased cost and GHG emissions due to the need to transport grain by truck or rail. The draft EIS fails to consider that barge shipments have declined 70 percent in the past two decades and that rail and truck are already on the way to becoming more economically viable. Investments in rail would also have numerous benefits beyond transportation in grain, including the potential for cheaper container shipping and passenger rail travel.	Access to barge transportation is the most cost effective means of accessing export markets for the majority of grain producers in the Pacific Northwest currently and removing that option will increase transportation costs for grain producers and increase air emissions, as the EIS shows. It is true that barge movements on the Snake/Columbia river have declined somewhat over the past 20 years, but not by 70 percent. As Table 3-229 in Section 3.10.2.1 shows, over the past 18 years, Snake River tonnage has decreased by 1.7%. That decline is mostly attributed to investments in shuttle rail terminals.
14	4	tcuezze@gmail.com	N/A	As for irrigation, pipeline extensions to draw water from the current level of the river would be cheap and practical.	This EIS discusses engineering solutions (pipeline extensions for example) in Section 3.12.3 Environmental Consequences - Specifically under Region C under the MO3 alternative (see page 3-1267, line 3244, in the Draft EIS) and in Appendix N. The report which this EIS draws upon, as discussed, concluded that modifying the existing pump system was cost prohibitive. In Region C under the MO3 alternative this analysis accordingly concludes that pumps are unable to deliver water to estimated at 48,000 acres.
14	5	tcuezze@gmail.com	N/A	Lastly, the draft EIS overstates cultural and economic impacts to local economies while ignoring benefits further out. The EIS emphasizes the loss of "riverport identity" of towns in the region and current flatwater recreation opportunities. However, a restored lower Snake River would provide many opportunities that the current system of sterile and slow-moving reservoirs does not. A restored Snake River would provide many opportunities for whitewater kayaking, rafting, and canoeing. Land previously submerged between the dam could be converted into a matrix of parks and agricultural areas which would both support local communities and provide interesting recreation opportunities. Located within a day's drive of the major metro areas of Portland and Seattle, a restored river has enormous potential to become a major opportunity. In contrast, reservoirs are abundant throughout the Northwest and attract little in the way of tourism. If towns can develop a "riverport identity," could they not also develop a "swiftwater identity?"	The social welfare effects on fisheries under MO3 are described as major and beneficial in the long-term, with increases in regional economic effects if commercial fish catch rates increase. For the effects on recreational fishing under MO3 (Section 3.11.3.5), the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River). There is some uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. However, the EIS does describes that the visitation in the long-term, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting recreation and tourism businesses.
14	6	tcuezze@gmail.com	N/A	Healthy Columbia Basin salmon populations would also have huge cultural significance for native tribes and residents of the Northwest as a whole. More salmon would aid in the recovery of Southern Resident Killer Whales, a Northwest icon currently endangered because of low salmon population. Salmon fisheries along the coast would become much more economically viable, a boon to challenged seaside communities. Fishing and gathering rights guaranteed in treaties to Native groups would be restored, as would many important cultural sites.	Thank you for your comment.
27	1	cakoncal@msn.com	N/A	I would like to see an assessment and educated opinion on the impact of overfishing on the salmon and steelhead. Overfishing is a problem worldwide. It includes the oceans and affects fish count in theColumbia. This problem is never mentioned as a root cause. Both commercial fisherman as well as net-fishing Tribes up and down the Columbia are the causes.	Alternatives to include changes to harvest are not within the scope of this EIS. A recent EIS addressing harvest was conducted by NMFS. We cited this study in Chapter 3.15 as we used its results to determine abundance considerations. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and Harvest certainly has an effect on salmon and steelhead populations. The three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors.
104	2	pearl.momilani.barry@gmail.com	N/A	the federal government has ignored sound science. Tribal, state and federal fisheries biologists have all supported the removal of the four lower Snake River dams as a keystone action necessary for any valid salmon plan. To date, the federal government has ignored this scientific consensus due not to scientific principles, but rather due to political issues. Instead or providing more water, more spill over the dams for safe passage, and dam removal, the federal government has relived on old actions like barging and trucking salmon around the dams and limiting the amount of water in the river that science has shown over and over again simply do not work. In order to restore Snake River salmon populations to sustainable numbers, scientists have determined that they must consistently return adults to the uppermost Snake River dam, Lower Granite, at a minimum rate of 2% to 6%. Since 1975 when the eight dams (four on the lower Columbia River and four on the lower Snake River) were completed, return rates have only rarely exceeded the 2 percent survival minimum. From 1994 to 2004, they ranged from 0.35 to 2.5 percent, exceeding 2 percent in just a single year. An extensive modeling effort completed in 2000 analyzed of the causes of mortality for Snake River salmon. The model demonstrated that the four lower Snake River dams were the most significant factor preventing recovery. The cumulative effect of eight dams on the lower Columbia and lower Snake Rivers is too much for salmon survival and if the four dams on the lower Snake were removed (cutting the total number of dams Snake River stocks face in half), these salmon can rebound to healthy levels.	As required by NEPAs implementing regulations, the co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the alternative that includes the measure to breach the lower Snake River dams. However, the Preferred Alternative also meets the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The alternative that includes the measure to breach the lower Snake River dams, by contrast, has significant regional economic effects and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend that alternative (MO3) because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
188	1	jaybird@odessaoffice.com	N/A	Let's also replace the 36,000 MW of power generating capacity of the dam's with 36 ? 1000 MW nuclear power generation plants, which would be a little over one nuke plant per county in Washington; or spread the nukes around a little into Canada, Idaho and Oregon.	For the EIS replacement resources, we used the Northwest Power and Conservation Council's 7th Power Plan and Mid-term Update to prioritize replacement resources. Conventional nuclear power is not on the Council's list of resources to consider, and Small Modular Reactors are classified as "Emerging/Long-term: Resources that have long-term potential in the Pacific Northwest but that are not commercially available yet.
188	2	jaybird@odessaoffice.com	N/A	As I have mentioned before to Cathy McMorris-Rodgers and also the Bonneville Power Administration, we should: 1) leave the dams where they are, best operate to generate power, control water flow, and provide for navigation of commercial shipping, 2) as dams generate power from their huge upstream STORED ENERGY DEVICES, which ALREADY EXIST (duh!), are PAID FOR (?), and are very USEFUL and BENEFICIAL behind each and every dam, for a number of reasons (including we then don't need to develop and construct HUGE BATTERY(?) STORAGE SYSTEMS (which don't exist!!), 3) then pump the downstream water from each dam back upstream over the top of the dams into their existing stored energy pools, by installing downstream variable-speed pumping stations and piping for reusing the water (I call it DYNAMIC PUMPED STORAGE?), all of which is commonly used technology and commercially available today, and a not a huge cost to purchase and install compared to the other pursued alternatives, 4) and then hard-wire connect at least the 10,000-15,000 MW of variable wind and solar power generation along the Columbia etc., to power the required banks of dam(n) downstream variable speed pumps for whenever the wind blows and the sun shines, eliminating the numerous other, worse(?) alternatives to deal with the transmission and use of the variable power, including the upsetting of the existing grid which can't handle more than about 15% contributions of variable power, 5) now then, practice DYNAMIC PUMPED STORAGE at each available chosen dam and upstream storage reservoir until one of two limiting conditions occur: a) the dams overflow, or b) there is insufficient flow to maintain navigation for ocean-going ships along the Columbia-Pacific Ocean waterway. 6) Now then, for the other greenie's? and protestor's?, when we have excess variable power and excess water along the Columbia, build a piping system to divert Columbia River water using these same downstream variable speed pumping stations to transport excess water to refill Lake Powell and Lake Mead (that could be done in a few months) in order to rehydrate the Colorado River water system so that they can then use the excess water to generate their own power in their existing dams plus maybe provide enough water for the Colorado to reach the Pacific to satisfy	The comment that the lower Snake River dams are important for regional power system reliability and the integration of additional renewables is consistent with the findings of the EIS. The EIS did not consider the type of large scale adaptations to the potential storage capabilities the commenter describes. Appendix H discusses pumped storage as a potential resource for the zero-carbon portfolios, however it was not included in the base case MO3 portfolio. The energy sector is constantly undergoing transformation. With new technologies and practices being introduced all the time, the analysis in the EIS is unable to capture all potential permutations of new and emerging resources because to do so would be too speculative. As such, the EIS analysis focuses on technologies that are currently in operation that are (or are capable of) utility-scale performance. The source of information used in the EIS is from the Northwest Power and Conservation Council's 7th Power Plan and Mid-term update. The EIS acknowledges that technological improvements will likely bring other options.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				California for both their power and water demands (which of course the cost of both would need to be sufficiently high as a toll cost to pay for the system and it's operation).	
614	1	troylberglund@gmail.com	N/A	Lastly, I am skeptical of effectiveness of increased spill. While the flex spill option seems to try and find a balance, the wide ranges of modeling results between the two models used in all the spill options considered highlights the lack of knowledge about if increased spill actually helps salmon in a meaningful way. Since increased spill results in less carbon free electricity production, this should only be done if we are 100% sure it will significantly help salmon. If any spill is done above the 2016 levels, which the preferred alternative calls for, we must conduct thorough ongoing evaluations and if we can't produce indisputable evidence that increased spill is significantly helpful to fish, we should reduce the spill immediately and focus on carbon free energy production	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the biological models and to help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored, as will the effects to generating resources around the basin. The associated carbon output of those resources will continue to be a focal point in regional power planning efforts.
712	1	N/A	N/A	These four dams are losing money each year, Bonneville Power Administration (BPA) has to borrow $1.6 billion from the federal government (taxpayers? money) over the next 2 years just to maintain the four lower Snake River dams. It would only cost $340 million to breach all four dams. If we breach the four lower Snake River dams this year, Eastern Washington would gain $200-300 million in economic benefits every year and an average of 3,000 jobs annually would be created.	The cost to breach the earthen embankments of the lower Snake River projects and drawdown the reservoirs is described in Annex A of Appendix Q, and is estimated at approximately $995 million. The economic benefits of breaching are provided in Section 3.19.3. In addition, there would be benefits to river-based recreation, including recreational fishing (Section 3.11), and commercial fisheries (Section 3.15). The EIS evaluated beneficial and adverse effects across an array of resource areas, including potential effects at the national, regional and local level. The EIS does not employ a cost-benefit framework for decision-making. Consistent with National Environmental Policy Act (NEPA) analysis framework, the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. Consequently, a focus solely on the monetized economic costs and benefits would exclude important tradeoffs associated with the alternatives communicated in the EIS, including effects on fish. Furthermore, the EIS evaluates the performance of the CRSO EIS alternatives with respect to multiple stated objectives, for example related to improving fish passage and survival, reliable power generation, and minimizing greenhouse gas emissions. Table 7-1 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives. When considering hydropower only, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 in the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170 in the Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review[1], the Headwater/Lower Snake Asset Class[2] is forecast to have a 50-year levelized cost of generation[3] of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020. 1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant Federal Columbia River Power System (FCRPS) capital and expense (O&M) spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized cost of generation is defined as the forecast direct costs and administrative overheads of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
1290	1	lytetch@yahoo.com	N/A	While I acknowledge the concerns made by those promoting their removal, they are wholly focused on impacts to the fisheries. Hydroelectric dams are one of the cleanest and most reliable green energy sources. They can be ramped up and down to satisfy periods of peak and low demands, unlike large fossil fuel, nuclear and green energy sources. Their availability is predictable unlike wind and solar. The proposals to remove the hydroelectric dams do not provide an explanation of how the lost generating capacity will be made up. With the removal of many fossil fuel plants, lost hydroelectric capacity may be made up with natural gas turbines for peak demands and nuclear energy for sustained demands.	The commenter is correct that hydroelectric dams produce clean and flexible power that is more predictable than other zero carbon resources, such as by wind and solar. The EIS examines several alternative resource portfolios that have characteristics similar to, though not complete replacements for, the attributes of the four lower Snake River dams that would be lost if breaching occurred under MO3. (See EIS Section 3.7.3.5 in the draft EIS). One of these alternative resource portfolios is a zero carbon replacement scenario, which includes solar, wind, and storage technologies (e.g., batteries). As explained in Section 3.7.3.5 of the draft EIS, replacing the four lower Snake River dams' capability with zero carbon resources would require solar and storage technologies at levels that are above current utility scale quantities.
1290	2	lytetch@yahoo.com	N/A	There is very little discussion from the environmentalists on what the economic impacts would be from the removal of the dams. What is the environmental impact of shipping all of the goods that currently travel by barge to now be shipped by rail or by truck? What is the cost to irrigation districts to reconfigure water supply systems for lower and changing water levels? How many will be unable to provide a consistent supply of water? This affects individual's livelihoods and the nation's food supply. I encourage every decision maker involved in the process to weigh all of the benefits of the hydroelectric dams and substantial impacts of their removal as a whole and not just focus on one aspect.	The potential economic effects from breaching of the lower Snake River dams are presented in the EIS, organized by resource area and type of economic effect, with additional details provided in resource specific appendices. Economic effects are described for changes to Power and Transmission (Section 3.7), Navigation and Transportation (Section 3.10), Water Supply (Section 3.12), and Recreation (Section 3.11). Potential economic effects are evaluated for social welfare effects (national economic effect), regional economic effects, and other social effects. Additionally, the environmental effects associated with increased emissions from shipping goods by rail and/or truck are evaluated and described in the Air Quality Section (Section 3.8), and increase health and safety concerns are described in the Navigation and Transportation Section for other social effects (Section 3.10.3.5). Removal of the dams has the potential to drop surface and groundwater levels up to 100 feet and it is not possible from an engineering or cost standpoint to replace the delivery mechanisms. Assumptions regarding the cost of reconfiguring water supply systems are discussed in the Water Supply Environmental Consequences Section for MO3 (Section 3.12.3.4, Region C). Effects to livelihoods are captured to the extent possible in the regional economic effects and other social effects sections that follow. Please see Section 3.12 and Appendix N for additional information.
1427	1	mlgriffith@frii.com	N/A	Meanwhile, the salmon are unable to get up River to spawn, their counts are dwindling, and the Pacific Northwest Orcas (residents) are STARVING. The 4th dam isn?t even a hydroelectric dam but still puts an impediment in the River. You don't have to destroy the dams to help the salmon get up River. Build a channel around the dam that can be opened during Salmon seasons to let them get up and back down the river.	Comment reviewed and considered. Because there are no references to sections, pages, or line numbers of the Draft EIS, no changes can be recommended based on this comment. All fourteen dams within the CRS generate hydropower. Eight dams on the lower Columbia and lower Snake rivers have existing fish passage facilities.
1493	1	N/A	N/A	You should really consider the recent EIS on the removal of dams on the lower Snake River in Idaho. Yes it takes work and sacrifice, such as possible energy price increase, and irrigation issues to work around, but the results would be worth the sacrifice. Efforts to restore and preserve Salmon and Steelhead populations would be appreciated by our children and grandchildren	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
1684	1	Martin_Drumm@yahoo.com	N/A	The reasons for decline in salmon populations are more complex than higher spill rates can rectify. Although increased spill rates at appropriate times have been shown to slightly improve salmon migration, the effect has not been significant. Most importantly, higher spill rates are not significantly increasing salmon return rates which points to problems in the ocean that will not be solved by higher spill rates.	We agree that there are many factors that contribute to salmon and steelhead populations including changes to ocean conditions, predation, harvest, etc. The analysis in this study focus on the migratory effects to salmon and steelhead from the operations, maintenance, and configuration of the Columbia River System projects. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm . In its analysis of effects, the Draft EIS used high quality data and best science, including models and studies published in peer review science journals. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. Modifications to the no-action alternative, such as changes in flows, were incorporated into the fish modeling. With respect to the preferred alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The COMPASS and NMFS Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that will assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. The framework for the adaptive management process is detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the CRSO EIS.
1684	2	Martin_Drumm@yahoo.com	N/A	On the other hand, higher spill rates can and probably will have an significant impact on the Columbia basin economy and environment. Replacement energy is much more expensive and will make it harder for Washington to reach its objective of providing carbon-free energy. The mostly rural economy of the Columbia River basin is much more sensitive to energy costs than the western metropolitan areas so the negative economic impact of higher spill rates will also fall disproportionally on the eastern rural areas which already significantly lag behind western metro regions.	The comment that replacing the four lower Snake River dams under MO3 would drive up costs in the region is consistent with EIS findings. Whether this affects the ability of Washington to reach its carbon free energy targets is uncertain; however, the EIS acknowledges that MO3 would make achieving these goals more difficult. The Environmental Justice analysis in Section 3.18.3 and Chapter of the Draft EIS provides further detail on potential disproportionate effects to Tribal, low-income and minority populations. Chapter 5 of Appendix H, Power and Transmission, provides additional details on potential rate increases by county as well as for urban and rural utility customers. The EIS recognizes the concern voiced in the comment regarding increasing power rates. Under the Preferred Alternative the Bonneville wholesale power rate pressure is estimated to be 2.7 percent relative to the No Action Alternative. A portion of that rate pressure has already been incorporated into the BP-20 wholesale power rates; and, the remaining rate pressure likely falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control.
1694	1	mkhoban@hotmail.com	N/A	Spend the money needed to remove the dams to improve handling of fish / fingerlings above and below the dams. Put good minds to work on that. Use the new "fish cannon" or other fish transport system.	The co-lead agencies received additional comments related to use of water cannons, or similar proprietary adult fish passage devices. The current configurations of the CRS dams that have fish ladders already have effective upstream adult passage. Many of the considerations for structural changes proposed in the EIS would be to address downstream juvenile passage and survival, as well as habitat concerns. The technology of fish cannons or similar devices will continue to be evaluated for future applications.
1788	1	N/A	N/A	Our efforts and resources would be better spent on developing improved salmon survival methods, including areas not associated with dams (ocean predators, etc.).	We agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. The Draft EIS describes and acknowledges the multitude of factors that affect salmon and steelhead throughout their life cycle in the Affected Environment. The EIS analyzed the effects of the different alternatives to operations, maintenance, and configuration of the CRS projects. The scope of the Draft EIS focuses on the area affected by the alternatives presented for operation and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
1794	1	Lon@nw-econ.com	N/A	The Draft EIS (at 27) contains the following conclusions. (1) "GHG emissions would increase the most if the hydropower were replaced with natural gas." (2) "This increased reliance on fossil-fuel-based resources is estimated to increase power-related emissions by 2.7 percent (1 MMT of CO2) across the region even assuming the new replacement resources are other renewables." These conclusions assume that natural gas is the only fuel that would be burned in over 1,000 MW of new combustion turbines. This assumption is likely incorrect and should be reconsidered. On March 10, 2020, "[t]he Intermountain Power Agency (IPA) ... awarded Mitsubishi Hitachi Power Systems (MHPS) a contract for two M501JAC power trains for the Intermountain Power Plant (IPP) in Delta, Utah." These new power trains will be fueled by a mixture of 30% hydrogen and 70% natural gas when they go on-line in 2025, and 100% hydrogen by 2045. See https://amer.mhps.com/intermountain-power-agency-orders-mhps-jac-gas-turbine-technology-for-renewable-hydrogen-energy-hub.html. An increase in GHG emissions due to the removal of the Snake River Dams is not a foregone conclusion.	The commenter describes an emerging technology that may serve as potential replacement resources that would reduce the greenhouse gas (GHG) emissions from new combustion turbines. The energy sector is constantly undergoing transformation. With new technologies and practices being introduced all the time, the analysis in the EIS is unable to capture all potential permutations of new and emerging resources because to do so would be too speculative. As such, the EIS analysis focuses on technologies that are currently in operation that are capable of utility scale performance. The source of resource information used in the EIS is from the Northwest Power and Conservation Council's Seventh Power Plan and Mid-term Update. The EIS acknowledges that technological improvements will likely bring other options. The conventional least-cost and the zero-carbon resource portfolios were intended to provide a range for the cost and emissions effects of the alternatives assuming current technologies could be scaled to replace the four lower Snake River dams capabilities.
1799	1	ricksharp1@hotmail.com	N/A	Dam removal is not a viable option without data models exploring the changes and disruptions of the below listed areas and agencies of concern, consider off shore netting restrictions and catch limits for salmon and other species.	Harvest and catch limits are outside the scope for this EIS, but the EIS does acknowledge that changes in abundance may affect harvest and catch limits. However, NMFS recently completed an EIS that analyzed effects of harvest on Columbia Basin salmon and steelhead. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the alternative that includes the measure to breach the lower Snake River dams (MO3). However, the Preferred Alternative also meets the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic effects and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
1815	1	will.e.putnam@gmail.com	N/A	"The Corps has a fiduciary responsibility (ultimately derived from the Public Trust Doctrine) to protect the public interest and to fund only beneficial projects. A 'beneficial project' is measured by the National Economic Development benefit-to-cost ratios (BCR) as exceeding 1; meaning for every dollar spent, at least one dollar in benefit is returned. The LSRDs have a combined BCR of 0.15:1. This means the LSRDs are returning only 15 for every $1 invested; we are losing $0.85 for every dollar we spend. This pales to projections that a free-flowing Lower Snake River could return $4-$19 for every $1 invested depending on what was done with the free-flowing river post-breaching. This would be a BCR of 4:1 or 19:1, respectively. Protecting the publics interest means the Corps can place an underperforming project, such as the LSRDs, into a 'caretaker' or 'non-operational' status. This does not require a specific or new authorization from Congress, nor does it require that the project be 'deauthorized' by Congress first. Thus, the Corps has the fiduciary responsibility to place the LSRDs into a non-operational status, based on the BCR." (Jim Waddell in "5 Means For Breaching The Lower Snake River Dams" paper https://damsense.org/wp-content/uploads/2019/01/5-Means-Rewrite-10-Oct-2018.pdf).	A benefit cost ratio was not calculated for the CRSO EIS. It is not a requirement of NEPA nor is it the basis of alternative selection under NEPA (see 40 C.F.R. 1502.23). Instead, the direct and indirect effects to the natural and human environment were evaluated, including some effects that were evaluated quantitatively and monetized, while others were evaluated qualitatively. New congressional authority and appropriations would both be required to implement the dam breaching measures in MO3. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes.
1815	2	will.e.putnam@gmail.com	N/A	"The purpose of this letter is to warn you of several misconceptions regarding the U.S. Army Corps ability to quickly execute the breaching of the four lower Snake River dams (4LSRDs). Government data and evidence shows immediate breaching is in fact the only available remedy remaining which can quickly supply and recover adult Chinook for the Southern Resident Killer Whales (SRKW) in time to prevent their virtual extinction. NOAA historically estimated that 25% of the SRKW diet was derived from the Snake basin. However, with the collapse of the Frasier River and the declining Salish Sea and mid-Columbia runs, this is now well over 50%; as evidenced by the shift in residency of these whales spending much more time at the mouth of the Columbia River/coastal areas. All other past attempts and those laid out by your SRKW Task Recommendations cannot overcome this deficit. Even NOAAs 2017 Spring / Summer Recovery plan says that despite an extensive list of actions, none of them will recover these stocks. This is why immediate breaching of lower Snake dams is so critical since each dam and reservoir will kill approximately 2 million Chinook smolts starting in April of 2019. Each breach will allow several hundred thousand of these to grow big enough for orca and fisheries within 14-18 months post dam breaching. Nothing can achieve this quicker in terms of overall number and timing ...	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Life Cycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (tules and brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by USFWS.
1815	3	will.e.putnam@gmail.com	N/A	Because the 4LSRDs are failing to meet the national economic objectives dictated by Congress, (benefits must exceed costs; the 4LSRDs are well below 1-to-1); they fail to provide for salmon recovery; the Corps and Bonneville Power Administration (BPA) have insufficient funds to maintain all dams in the Federal Columbia River Power System (FCRPS); 99% of the power produced by the 4LSRDs is surplus and sold at a loss; they cannot provide peaking power; and these dams are the most expensive of the larger dams in the federal system. Therefore, the Corps is obligated to place them into a non-operational status that does not require Congressional authorizations or new appropriations." (Jim Waddell and Ken Balcomb in 2018 Open Letter to Governor Inslee https://damsense.org/wp-content/uploads/2019/01/Inslee-ltr-12-Dec-2018.pdf).	As explained in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are among the most valuable projects in the Federal Columbia River Power System (FCRPS). These dams provide over 1000 MW of carbon-free energy and up to 2000 MW of peaking capacity at certain times of the year. The dams also have unparalleled ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2200 MW of capability in certain months of the year. Regarding costs, the four lower Snake River dams are some of the most reliable and lowest-cost electricity sources of the 31 Federal dams from which Bonneville markets power. Bonneville also has sufficient funds to support these, and all, FCRPS projects. Bonneville sets its power rates to recover its total system costs, including the costs of the four lower Snake River dams, and therefore, does not sell power from these projects at a loss. (See Draft EIS Section 3.7.2.7, Power Rate Determination). Rather, Bonneville recovers its costs and maintains sufficient funds to support the FCRPS consistent with its statutory mandates. Finally, Bonneville sells power from the FCRPS as a unified system, not from specific projects. In this regard, the power generated from the four lower Snake River dams are not exclusively sold as surplus, but rather is used to meet Bonneville's collective power obligation, most of which is sold to meet the loads of publicly owned utilities, such as municipalities, rural utilities, and public utility districts. (See Draft EIS Section 3.7.2.5, Bonneville Power and Transmission Customers).
1824	1	gary@dukelow.com	N/A	Retention of Snake River Dams Removal of the dams is predicated on the number of returning fish. However, improvements in the dams for fish migration upstream as well has been extremely successful with returning salmon up to almost 100% of what there were before the dams were built. This is despite the effects of sea lions eating a huge amount of returning fish. A study by the National Marine Fisheries Service found sea lions were eating between 20% and 43% of the spring chinook run of salmon on the Columbia River. Several failed, non-lethal strategies have been attempted to remove sea lions, which have been eating the endangered salmon and steelhead. Last year, sea lions at Willamette Falls ate a quarter of a winter steelhead run that was already down to about 500 fish. If people were really serious about further increasing the amount of returning fish, more sea lions would be killed than what recent attempts have allowed.	Sea lion management decisions at Bonneville Dam rely on input from the Sea Lion Management Working Group. This Working Group is a collaborative effort with NOAA, USFWS, various Tribes, and the co-lead agencies. The co-lead agencies work to minimize the effects of sea lions on salmon by implementing Best Management Practices specified in the NOAA Biological Opinion and by implementing recommendations developed by the Working Group. The co-lead agencies will continue to use this process to minimize the effects of sea lions on salmon. The EIS discusses the Working Group and sea lion management in Sections 3.5, 3.6 and Chapters 5 and 7. Other entities in the region (e.g., NMFS, the states of Oregon and Washington, and local Tribal governments) have authorities and obligations to mitigate the effects from pinnipeds, and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
1824	2	gary@dukelow.com	N/A	Removal of the dams would have the following impacts: Removing the four Lower Snake River dams would increase the cost of electricity in Washington state. The Snake River dams provide some of the lowest-cost electricity in the Columbia-Snake River system, even accounting for the costs to protect salmon. The Northwest is facing a shortage of electricity in upcoming years and destroying the dams would worsen that shortage. Although they dont store energy like other dams on the Columbia River, the Snake River dams can adjust the flow over several hours, providing reliable energy when wind and solar power are not available. Replacement energy is more expensive: Claims about hoped-for dramatic reductions in solar costs are often capacity weighted, which means they are based not on projected averages across states but are based on costs where solar is currently being built, which is primarily in the southwestern United States. If we were replacing the Snake River dams with solar power produced in Phoenix, Arizona these estimates might be useful. Since we are not, they are not. In addition, rather than wind and solar costs going down, projections are that the cost of installing them will increase. One of the arguments made by dam opponents is that the operation of the dams is subsidized by the federal government in a variety of ways. It is fair to argue that we need to be honest about the subsidies in the system. It is not fair, however, to complain about subsidies for the dams while ignoring the massive, and expiring, subsidies for energy like solar and wind power.	The comment about the importance of the four lower Snake River dams for regional power reliability and cost are consistent with the EIS findings. The EIS uses the best available recent estimates for regional power costs, and balances potential resource costs by examining two potential replacement scenarios. The zero-carbon (largely solar power) was more costly than natural gas portfolio option but was still less costly than other scenarios tested such as wind power in the Columbia River Gorge or Montana. The portfolios and the methods underlying their selection are described further in Section 3.7.3.5, Potential Replacement Resources and Associated Costs as well as Appendices H, Power and Transmission and J, Hydropower of the draft EIS. Costs allocated to power at the four lower Snake River dams are not subsidized by the Federal government, but recovered through power rates Bonneville charges its customers and most frequently paid directly to the Corps pursuant to the agencies direct funding agreements. (See Draft EIS Section 3.7.2.6 Power Revenue Requirement).
1824	3	gary@dukelow.com	N/A	Guest column: Breaching dams wont help Orcas BY DAVE MCDONALD A recent Associated Press article (Oct. 30) tying the Snake River Dams to the livelihood of the Puget Sound Orcas left me scratching my head. Activists on the Seattle waterfront said the best way to save the Orcas is to restore the salmon runs that provide their food – mostly by removing the lower Snake River Dams. That is where the head scratching began. The inland waterway of British Columbia and Washington, the Salish Sea, is the favored habitat of the Orcas and where they spend most of their time. That obviously means the bulk of their salmon diet comes from the rivers emptying into those waters. The Columbia/Snake River system is not connected to that habitat favored by the Orcas. Breaching dams on a river system that does not connect to the main habitat of the whales is pointless. The geography doesnt work and the science is questionable (see NOAA Fisheries Service Report Southern Resident Killer Whales and Snake River Dams 2016). The activists described in the article on the Seattle waterfront were staring at the real problems and they are not the Snake River dams. The activists said nothing about the overwater structures, seawalls, bank armoring, bulkheads, breakwaters and filled estuaries that have decimated the nearshore ecosystem around Puget Sound. They said nothing about the destruction of ecological functions of the rivers and streams around Puget Sound. Those rivers and streams directly impact the whales because they are a major part of their favored habitat. To ensure the long-term survival of the whales, restoring the Puget Sound shoreline habitat and rivers must be the priority. The vital nursery, rearing and feeding areas for juvenile salmon along with migration	The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Life Cycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				routes in the sound have been totally disrupted. The lack of a natural habitat for salmon along the shoreline of Puget Sound has hurt well-being of the whales. Instead of wasting money on the Snake River Dams, put it to better use in the whales front yard and do something to directly benefit them. The whales are swimming in sewage from the Victoria outfalls and all the filth oozing into the Sound from surrounding urban areas. Carkeek Park creek in north Seattle has a sign warning people to avoid the water because of the fecal matter in the creek. All this waste matter is fouling the whales' habitat. Removing the Snake River Dams will not stop the fouling of the Puget Sound waters. Cleaning up superfund sites in the Sound is good but how about also restoring the estuary around the mouth of the Duwamish River. How many of the Puget Sound rivers are dammed? Would removing the Howard Hanson dam or part of the six dams on the Skagit River system help with river restoration? Would closing the mouth of the Duwamish River to boat and ship traffic during the migration periods for salmon improve their survival rates? These are the issues that should be addressed. If we are truly interested in helping the Orcas lets focus our limited resources on improving conditions in the Salish Sea, the home of the Orcas. The Snake River Dams are just a distraction from what really needs to be done	whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the CRS project. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
1825	1	kazthea@mac.com	N/A	The new proposed fall temperatures would allow a 2.6 degree increase. It would also allow Idaho Power to spend less on mitigation to meet standards that are never met anyway. Idaho and Oregon must sign on to the new temperature standard, which Idaho has already done. Shame on the state of Idaho! Fall is a critical time for fall chinook spawning that would help boost numbers of naturally reproducing spawning fish.	The EIS scope is limited to operation, maintenance, and configuration of the Columbia River System projects. The CRSO EIS does not evaluate changes to water quality standards nor changes in Idaho Power's operations of the Hells Canyon complex. Analysis of MO1 indicated an increase in lower Snake River temperatures was an unintended consequence of a measure intended to cool the river, so that measure was not carried forward to the Preferred Alternative.
1853	1	fordrattler@charter.net	N/A	I am concerned that breaching the lower Snake River dams not be an option to go forward with. I am of the opinion that this will increase green house gases by adding more truck traffic onto to the roads for agriculture and shipping of goods in the area. It will eliminate the barge traffic that is a good alternative to trucking. It will increase the need for more expensive electricity that the dams deliver in a carbon free state as they are now. The air quality with all the increased truck traffic will decline. There are not enough other environmentally friendly alternative energy sources that will be able to make up the energy provided by these hydro electric greenhouse friendly power sources.	The commenter's concern that breaching of the four lower Snake River dams will cause increased emissions and higher regional electricity prices is consistent with the findings of the EIS. The EIS considers a zero-carbon replacement resource portfolio to replace the capability of the four lower Snake River dams in Section 3.7.3.5, Potential Replacement Resources and Associated Costs. However, the Draft EIS also found that even assuming this zero carbon portfolio was selected, net GHG emissions may increase because existing fossil-fuel generation plants would also increase generation to maintain regional reliability. The Navigation and Transportation Section (3.10) reflects the adverse effects of implementing MO3, including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Similarly, Section 3.10 also describes increased safety concerns from the additional truck traffic resulting from MO3.
1873	1	rwrussell3@gmail.com	N/A	While I am concerned with the declining number of Southern Resident Orca whales, I do not believe this draft EIS has adequately analyzed the comparative impacts of dam removal to mitigation, for example, of salmon habitat around Puget Sound.	MO3 include a measure to breach the four lower Snake River dams. The effects of and mitigation associated with MO3 are captured in Chapters 3, 4, 5 and 6. Mitigation for the Multiple Objective Alternatives 1, 2, 3, and 4 is are described in Chapter 5. Mitigation for the Preferred Alternative is discussed in Chapter 7. As the project scope of analysis is on the operations maintenance and configuration of the 14 Federal dams on the Columbia and lower Snake Rivers, no effects on these operations are anticipated to effect salmon habitat in Puget Sound. Additionally, Puget Sound salmon do not use Columbia River habitat. While this EIS does not include an assessment of Puget Sound habitat, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon all around Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project. For more information on this work and partnership, visit http://www.pugetsoundnearshore.org/
1888	1	N/A	N/A	Instead of just pulling them out we should first come up with alternatives to replace power production and water storage. Victor Shauberger suggested to look to nature to solve these types of problems. The solution begins upstream with the various forks of the Snake River. The first thing to do is strategically place large rocks on both sides of the stream to create a fast moving channel in the middle and provide vortex swirling that allow beneficial travel and habitat for fish. The next step is to place some kind of pipe with holes in the top and screens to allow water to come in and debris and wildlife to stay out. The topography of the land should indicate where the best areas for water storage are. Instead of a large dam several reservoirs need to be placed to replace and potentially increase water storage. Same with the large dam turbines, several smaller turbines taking advantage of the faster current could be used to create and spread out power distribution or from one reservoir to another using a funnel shaped device to create a vortex which will help purify and add oxygen to water which will help wildlife and water quality. Also spiral or pipes with indentations will also create vortex effect. This will also increase velocity for electric turbine generators. Using gravity as much as possible will reduce workloads of irrigation pumps but some areas will still require power to pump uphill. Solar and ventilator type wind turbines could also be used where irrigation pumps are placed same with existing wind turbines which in my opinion are a bad design, hard to work on, and an eye sore but they already exist. In the long term these designs will produce more power and be more easily maintained and serviced than traditional dams plus they are more in harmony with nature. The Swiss as well as a guy in Texas are already using these principles for various applications. The key will be water collection and storage during peak runoff which the dams sometimes dont take advantage of. Anyhow Im sure theres enough hydraulic engineers working for the Core of Engineers to figure it out. Just figure out exactly how much power and water storage the dams are producing starting with the furthest upstream and replace and exceed current capacity before removing each dam.	The replacement resource scenarios described in the EIS are designed to ensure that the effect of breaching the four lower Snake dams on regional power reliability is minimized to the extent possible, taking into consideration the costs. The EIS recognizes that there are multiple ways that the generation losses from the dams could be replaced and relies on the best information currently available to identify cost-effective replacement scenarios. The co-lead agencies appreciate the insights in this comment regarding innovative project designs for replacing the power; however, information is limited to evaluate how effective these projects would be, so is not within the scope of this EIS.
1895	1	stevepettee@sbcglobal.net	N/A	Secondly, once reservoirs are drained, vast areas will open up to scavengers for Indian artifacts just like what happened when Priest Rapids Dam was recently lowered to make repairs. Those artifacts are currently protected and should stay that way for the next several hundred years.	The co-lead agencies did not identify MO3 as the Preferred Alternative in the Draft EIS. The co-lead agencies agree the potential exists for archaeological looting of exposed cultural resources to occur in the reservoirs following the breaching of the four lower Snake River dams under MO3. To mitigate for this potential effect to cultural resources under MO3, the co-lead agencies proposed several measures in Section 5.3.3.7 and Table 5.1, in the Draft EIS. Some of these measures include protective fencing, public relations activities to deter archaeological looting, implementation of any needed data recovery or emergency excavation of archaeological resources, and increased law enforcement patrols to also deter looting.
1901	1	gamerrick@startmail.com	N/A	The Dams Are Just One Factor in Salmon and Orca Survival Salmon from the Snake River are only one part of an orcas diet. Salmon survival rates through these dams are as high as 97%. NOAA Fisheries analysis shows Puget Sound Chinook salmon are most important for the Southern Residents. Cleaning the Puget Sound and reducing carbon output would be a better use of time and money in saving our treasured salmon and orca.	We agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm Many of these effects are outside the scope of this EIS, which analyzes the effects of operations and maintenance of the CRS dams, including cleaning the Puget Sound. However, However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by National Marine Fisheries Service (NMFS) in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the CRS directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these Federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin, including both hatchery and wild produced fish, are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). Reducing carbon output, as a general matter, is outside the scope of this EIS, but the EIS analyzes effects of the range of alternatives on greenhouse gas emissions and climate change in Section 3.8 and Chapters 4 and 7.
1901	2	gamerrick@startmail.com	N/A	The Dams Meet Washingtons Carbon-Free Goals Washington states Clean Energy Transformation Act (CETA) commits us to a path of no coal generation by 2025 and 100% clean energy by 2045. Zero carbon emissions are produced during hydropower generation. The Dams Provide Affordable Electricity Several independent studies indicate a shortage of electricity generation in the coming years, particularly with the closure of coal plants. The lower Snake River dams are critically needed to avoid a repeat of the 2000-2001 energy crisis that resulted in soaring electricity prices. The draft EIS indicates that replacing lost generation from dam removal with carbon-free resources could result in a 50% increase in power costs. That doesnt consider the loss of coal generation which will also need to be replaced by carbon-free resources to reach CETA goals. A rise in energy costs would worsen our homeless crisis and mean greater hardships for people already struggling to make ends meet.	The comment that four lower Snake River dams produce zero carbon emissions, and that replacing the four lower Snake River dams under MO3 will drive up costs in the region is consistent with EIS findings. The Environmental Justice analysis in Section 3.18.3 of the Draft EIS provides further detail on potential disproportionate effects to Tribal, low-income and minority populations for MO3. Chapter 5 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers.
1904	1	ruppert228@aol.com	N/A	3.) Higher spill rates are expensive and unproven. According to one of two fish survival models outlined in the EIS, this would decrease fish survival rates. For more details on each of my arguments, you can refer to Benton REA's letter to it's customers entitled "Your Action Is Needed To Save The Lower Snake River Dams" dated March 2, 2020.	In its analysis of effects, the Draft EIS used high quality data and best science, including models and studies published in peer review science journals. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the preferred alternative, the CSS model predicts that average Smolt to Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the preferred alternative. The COMPASS and NMFS Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. The framework for the adaptive management process is detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS.
1952	1	n.highland@charter.net	N/A	I do not feel that an adequate case has been made concerning the relationship between the dams, salmon survival rates and orca survival. It would seem that a focus by others on cleaning up Puget Sound and further reducing carbon output would go much further to benefit the salmon and orcas.	We agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions would generally continue to ensure compliance with the ESA. Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the CRS project. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project. Reducing carbon output, as a general matter, is outside the scope of this EIS, but the EIS analyzes effects of the range of alternatives on greenhouse gas emissions and climate change in Section 3.8 and Chapters 4 and 7.
1953	1	LDSpath1@cs.com	N/A	Why was Idaho Power left out of drafting this?	The CRS encompasses the 14 Federal projects on the Columbia River and its major tributaries (Figure 1-1). These dams are not operated by Idaho Power, so that is why it did not draft this EIS.
1955	1	w_sperry@hotmail.com	N/A	Please consider the far-reaching impact to human health and livelihood if dams are reduced or removed. I do not see that breaching dams is an answer to environmental problems and will not largely help the environment preservation over harming our safety and health we currently rely on	Through our analysis, the co-lead agencies concur that dam breaching has adverse impacts to both the human and natural environment. The analysis does show benefits for specific fish within the Snake River, but at the expense of other resources. Under MO3 (which includes the breaching of four lower Snake River dams), the impacts to human health related to changes of air quality, water quality and fish consumption is difficult to estimate, but is anticipated to be adversely affected, especially if the region does not take actions to resolve any water contamination or offset local air pollution. The Preferred Alternative was developed to maintain a balance of the benefits that can be achieved by modifying the operations of the 14 Federal projects, while minimizing any impacts to the natural and human environment.
1956	1	boxdorfabc@centurylink.net	N/A	Public comment meeting on Salmon in Boise?	In response to COVID-19 concerns and public health requirements within the comment period, the agencies converted the six planned in-person regional public comment meetings to conference calls that provided an approach consistent with the format of the planned in-person comment meetings. To ensure adequate opportunity for the public to provide comments on the Draft EIS, the agencies hosted an online comment platform, providing mailing addresses for written comments, and hosted a series of public comment meetings by telephone. The co-lead agencies offered these public comment meetings by telephone to maintain our commitment to accepting verbal comments in accordance with current public health guidelines. These teleconference meetings were structured similarly to the previously scheduled in-person public comment meetings and provided speakers with the same amount of time to submit a verbal comment. Due to the format of these meetings, they were accessible to any public commenter, regardless of location.
1973	1	kmazik@cox.net	N/A	Despite downward trending salmon and steelhead returns, the states first closed steelhead season due to abysmal returns in 2019, and 2020 returns that are predicted to be much of the same, the federal action agencies (Bonneville Power Administration, Army Corps of Engineers, Bureau or Reclamation) concluded that minimal change will come to fish management, even as Idaho communities experience economic hardships and an uncertain future. While the dEIS gave significant attention to industries of agriculture, subsidized barging, and power generation, Idahos (and WA and OR) rural fishing communities were literally left out of evaluating solutionso date, Bonneville Power Administration has spent $17 billion in fish recovery efforts to mitigate for downriver impacts with little to show for it. Yet despite evidence supporting a need for change, the draft plan seeks to continue with the same strategies and failed, irresponsible spending. Simply keeping salmon and steelhead on life support ignores the millions in economic benefits that healthy and harvestable returns would bring to Idaho. For all management alternatives and their Preferred Alternative, the economies of recreation and fishing (guiding, outfitting, hotels, restaurants, gas stations, boat shops, license fees, etc.) were not even accounted for despite existing, publicly available data. Idaho communities are speaking up, looking for leaders who are willing to ask hard questions and seek new and bold solutions that include all stakeholders, industries, and communities. The recently released draft environmental impact statement is not that plan.	The scope of the CRSO EIS covered eight objectives of which salmon, steelhead, and resident fish were three. In particular, the co-lead agencies developed measures to improve fish passage and fish flows, and reduce adverse impacts to spawning habitat. Fish harvest is the responsibility of NMFS and USFWS and continues to be researched by these agencies. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and Tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so. The co-lead agencies agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. Moreover, the comments suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA-listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979, report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
1976	1	nittgritty@yahoo.com	N/A	Why all of a sudden, after 50-60 years, our dams seem to be killing off the Salmon population and thus the Orcas. I believe the problem does lie in the Puget sound area and should be studied from that angle.	Effects to Southern Resident killer whales from actions in Puget Sound are outside the scope of the CRSO EIS. The U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project. Regarding Southern Resident killer whales (SRKW), the population dynamics of the SRKW are complicated, and there is no one factor that contributes to the overall success of this species; however, the co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Additionally, Section 7.7.8 states impacts to Southern Resident killer whales would be negligible. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative. These hatcheries include conservation and safety net hatcheries, as well as through the continued existence of certain independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by USFWS. Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW.
1985	1	bmeek@agrinw.com	N/A	Specifically: I am glad economic costs and alternative measures to help the Salmon, Orca, and other populations are considered. I am supportive of helping these species but get very frustrated when the role the dams play is overstated. I agree with the assumption used in the irrigated ag section that removing the dams would effectively end irrigated farming on the nearly 50,000 acres that rely on these pools behind the Ice Harbor Dam. I think your economic impact numbers for the farm value and workers on the farms themselves are reasonable. I do believe there should be additional impact factored in for the processors in the tri-cities who would have supplies reduced. If the acres in this area were lost, they cannot be replaced near the current processing infrastructure in Pasco.	Impacts to individual cities was not included in the EIS. However, regional economic impacts and considerations of the effect to areas were included, for example impacts to Water Supply including municipal and industrial and irrigation is described in Section 3.12. Approximately 4,800 jobs (or 5.9% of total jobs) within the Ice Harbor and Lower Monumental socioeconomic area are estimated to be lost related to MO3 irrigation losses. Navigation and Transportation impacts are addressed in Section 3.10. Indeed, there would be additional impacts to such industries like processing plants that would need to develop new relationships and supply chains for business should MO3 be implemented.
1985	2	bmeek@agrinw.com	N/A	Final comment: I can appreciate the frustration the tribes have feel for the ways they have been ignored and under considered in the past. They have legitimate claims that must be addressed. Having said that the argument that they continue to make that this has caused them to lose their traditions is significantly overstated. Human behavior and psychology are universal. My grandfather was a great horseman and wishes his grandchildren were also. Much to his frustration we have access to modern ATVs and that is what we prefer. To argue the younger generation would be significantly different in the embrace of culture and tradition without the dams is the denial of centuries of human behavior.	Thank you for your comment.
1986	1	N/A	N/A	Heres a potential way to replace the power generated by the Snake River dams. Instead of a large dam smaller concrete structures could be built that basically create a spillway that diverts water into a parabolic funnel fountain with multiple funnels. Basically a central stream that allows water to create a vortex that turns an inner funnel with opposing magnetic charges and a stator on outer funnel to collect charge. The water that comes out will be aerated and somewhat purified. It could be spilled back into the water or spilled into another fountain repeating the process depending on elevation change where it enters and exits spillway. These can be built to any scale depending on power demands. Also the double helix vortex created can also generate some power because it also creates a rotating field. Screens placed at spillway entrance will prevent wildlife and debris from entering spillway and fountain. Theres sediment collection devices that need to be added but heavy materials such as lead could be separated if theres a need like in the Columbia River. Ill provide a basic freehand top view sketch as a visual. Improving the water quality and adding oxygen should help. Better stream and flow management would also help. If the water is used for irrigation it will help farmers because it has more oxygen and it will move better through the ground because it has a slight charge. Theres better designs but the concepts are the same. Discharging through a spiral pipe would also increase flow. It should cost less than building dams and actually help improve the environment and wildlife while still producing the same or more electricity.	The replacement resource scenarios described in the EIS are designed to ensure that the effect of dam breach on regional power reliability is minimized to the extent possible, taking into consideration the cost. The EIS recognizes that there are multiple ways that the generation losses from the dams could be replaced and relies on the best information currently available to identify cost-effective replacement scenarios. The co-lead agencies appreciate the insights in this comment regarding innovative project designs for replacing the power; however, information is limited that would be necessary to evaluate how effective these projects would be.
2053	1	N/A	N/A	3. The Dams Provide Affordable Electricity - Multiple independent studies indicate a shortage of electricity generation in the coming years, particularly with the closure of coal plants. The lower Snake River dams are critically needed to avoid a repeat of the 2000-2001 energy crisis that resulted in soaring electricity prices. The draft EIS indicates that replacing lost generation from dam removal with carbon-free resources could result in a 50% increase in power costs. That doesn't consider the loss of coal generation which will also need to be replaced by carbon-free resources to reach CETA goals. A rise in energy costs would worsen our homeless crisis in the Tri-Cities and mean greater hardships for people already struggling to make ends meet.	The comment that breaching the lower Snake River dams and replacing them with alternative sources of energy would drive up costs in the region is consistent with the EIS findings. Likewise, the connection between reducing carbon emissions (under CETA and coal-plant retirements) is an area that the EIS considered. The Environmental Justice analysis (Section 3.18.3 of the draft EIS) provides further detail on potential disproportionate effects to Tribal, low-income and minority populations. Chapter 5 and Exhibit 1 of Appendix H, Power and Transmission in the draft EIS provides additional details on potential rate increases by county as well as for urban and rural utility customers.
2060	1	rslovic@gmail.com	N/A	The study has a glaring omission. It fails to take into consideration the costs of upgrading the aging Lower Snake River Dams. The breaching costs have always included the amount of money needed to provide irrigation from a free-flowing river and the costs of rail spurs to rail lines to accommodate the 2 million tons of grain that currently travels by barge. Longer trains and lighter larger cars that have been developed can accommodate the additional grain. Every ounce of grain currently travels by truck to the barges and silos. The irrational argument about increased truck traffic is meant to confuse and scare people. I doubt Lewiston, Idaho will mourn the loss of its port since it loses a lot of money each year. It hasnt made money in years.	The costs to breach the dams and draw down the infrastructure are described in Section 3.19 and in Appendix Q (construction costs of the structural measures).Tables 4-1 and 5-1 in Appendix Q show the costs and cost savings under MO3. There would be approximately $107 million in annual capital and O&M cost savings under MO3 compared to the No Action Alternative for the four lower Snake River projects over the 50-year period of analysis. The cost of breaching the dams, as described in Section 3.19 and in Appendix Q, does not include changes to irrigation or rail infrastructure. The Navigation and Transportation Section (3.10) reflects the adverse effects of implementing MO3, including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent).
2060	2	rslovic@gmail.com	N/A	The 98% figures given for overall dam passage survival of chinook, and steelhead strains credulity. It makes me wonder about the rest of the figures in this report. The study continues to conflate the breaching of the four Lower Snake River Dams with the entire Columbia River System. For instance, the study talks about flood control even though the LSRD werent built to control flooding.	The 96% and 93% survival targets in the 2008 Biological Opinion are based on survival at each individual dam and are not cumulative. The in-river survival estimates presented throughout the Draft EIS show the total freshwater juvenile survival rates of salmon and steelhead as they pass the multiple dams of the CRS. The Draft EIS references the number of dams included in each estimate and varies by species (e.g., Upper Columbia vs. Snake River). The Draft EIS contains detailed descriptions of each project and also details whether the authorized purpose of a dam includes flood risk management or not.
2078	1	jdmcive@gmail.com	N/A	The average return for steelhead over Bonneville Dam from 1938 to 1947 averaged 127,000 fish. From 2000 thru 2009, the average return was 401,000 steelhead, a 316 percent increase. For spring chinook salmon, the 1938 to 1947 average was 62,000 fish. From 2000 to 2009, the average return was 164,000 chinook, a 265 percent increase. In a book titled Against the Torrents, copy write 2016, Darrell Bentz, a jet boat builder and fishing guide on the Salmon river states in 2007 there was an abundance of fish. Abundance of fish? How can that be! The snake river dams had been in place for over 30 years and we had and abundance of fish. I would like you to task you to list what has changed since 2007. Did netting on the Columbia river change? Did hatchery production change? Did the way fish arrive at the ocean change? Have predators to fish changed? These are the questions that need answered, because the dams havent changed and allowed an abundance of fish to come up the snake and salmon rivers in the past. Get all the information first before blaming the dams.	We agree that there have been many changes in the basin that impact anadromous fish populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm While the CRS dams have been in place since well before 2007, the configuration of the dams and operations have changed in order to improve passage conditions for ESA-listed salmon and steelhead. In addition, predation from a variety of sources (e.g., avian, native and non-native fish predators, and pinnipeds) has increased since 2007. Please see the Affected Environment in Chapter 3 of the Draft EIS for more information.
2080	1	N/A	N/A	This draft EIS is described as evaluating the impact of dam operations on threatened and endangered fish populations. I have lived near the Columbia River for nearly 40 years and have had a number of opportunities to visit the dams and their visitor centers. One thing that struck me was the census of fish data and the great decline of fish due to the canneries and fishing that occurred long before the dams were built. The Columbia River hogs were fished out, long before dam construction. There are a number of other causes of fish mortality, including Caspian Terns, California Sea Lions, Northwest Pike Minnows, and the growing and spreading populations of white Pelicans. Fishing also continues, including the use of gill nets that stretch across the river. I did not see any mention of a root cause analysis for the complete causes and extent of causes for fish mortality. A root cause analysis would show that the dams, with their fish ladders, are way down the list and not a main cause. It does not make sense to remove dams. The causes of fish mortality are elsewhere. The Columbia River dams have provided an opportunity for better, healthier lives for residents in the region and around the country. Life expectancy and health have improved due to the accessibility of power and irrigation water and the improved distribution of crops.	We agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm The Preferred Alternative includes a large suite of predation mitigation measures, some of which include maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary. The co-lead agencies currently implement a Northern Pikeminnow Management Program which includes an ongoing base program and general increase in northern pikeminnow sport-reward fishery reward structure to reduce predation by these fish. This measure would continue under the Preferred Alternative. Management of gamefish such as walleye typically falls within the authority of state fish and wildlife agencies. This EIS analyzes the operations, maintenance, and configuration of the CRS projects. Many of the effects listed in this comment are outside of the scope of this EIS. The co-lead agencies also looked at the cumulative effects of other actions, including harvest, in Chapters 6 and 7 of the EIS. However, the three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. Research continues to evaluate the magnitude of these effects.
2084	1	jfix3371@charter.net	N/A	Alternative 3 has the inherent assumption that breaching the dams this would preserve the salmon and by inference the Southern Resident Orcas. As noted on page 91 of the Washington State (i.e., Governor Inslee) funded report* only some of the factors leading to salmon mortality will be alleviated by lower Snake River Dam removal, while others may be introduced. When projecting changes to mortality and salmon population recovery levels there is extreme uncertainty due to the variety and magnitude of factors that contribute to overall populations, many of which change on a year to year basis. The salmon and Orca situation is amplified in the October 2018 announcement by Canada to help maintain their Northern and Southern Orca Pods. The Canadian effort is particularly relevant to Alternative #3 evaluation in the draft EIS. This announcement states that the Government of Canada is taking immediate and comprehensive action to encourage the recovery of their Orca pods (and by implication salmon) by: reducing Chinook fishery harvesting to increase this food source for both the Northern and Southern Orca Pods; adding more fishery officers on the water to verify compliance; requiring a mandatory minimum approach distance of 200 meters for all Orca populations in British Columbia (BC) and the Pacific Ocean; installing under-water hydrophones in the Salish Sea to better understand noise levels and impacts on the Southern Residents; partnering with the Vancouver Fraser Port Authority Enhancing Cetacean Habitat and Observation (ECHO) program on a voluntary vessel slowdown in Haro Strait (where Southern Pod Orcas are often found) to reduce underwater noise levels of vessels using the port, with a current participation rate of around 90 per cent; increasing aerial surveillance patrols through Transport Canadas National Aerial Surveillance Program; conducting additional research in contaminants, and noise from marine shipping for both Northern and Southern Orca Pods; collaborating with the shipping industry, United States partners, and Indigenous peoples to put in place a trial in which vessels move away from key foraging areas of the Southern Pod Orcas by going further south within existing shipping lanes in the Strait of Juan de Fuca. working with BC Ferries to develop a noise management plan to reduce the underwater noise generated by their fleet, including commitments to buying quieter vessels; and increasing research, strengthening regulatory controls, and enhancing enforcement of environmental regulations to reduce contaminants affecting whales	Thank you for your comment and additional information. We agree that there is uncertainty in projecting future outcomes based on past results. We continue to refine our monitoring and modeling efforts to gain additional insights regarding salmon survival and returns. The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020).
2084	2	jfix3371@charter.net	N/A	The extent of the Canadian programs illustrate that problems are far greater than removing four large dams on a section of the Snake River. Certainly, the primary goal is to increase salmon spawning in various river systems with assurance that there will be a concurrent increase in salmon availability to the Orcas. Available peer-reviewed scientific articles** illustrate that much uncertainty exists as to the actual causes in the decline of salmon availability to the Orca Pods in the Pacific Ocean. These causes must be understood to enhance Orca survival particularly for a species that travels hundreds of miles each year, could easily travel to locations with greater salmon abundance, as well as marine mammal prey, such as seals and sea lions. The most likely outcome of Alternative #3 are continued declines in salmon and ongoing risks to the Orca while destroying the economic vitality of an entire region of south eastern Washington leaving the lower Snake River with large concrete monoliths instead of functioning dams. I question whether the authors of this report spent time examining the existing recreational activities associated with the lower Snake River dams.	We agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm The EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (tules and brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). Impacts to recreational activities were analyzed for each alternative, in compliance of the National Environmental Policy Act (NEPA). Recreation analysis is available in Section 3.11 of the EIS.
2101	2	thefranks5@msn.com	N/A	Regarding the salmon/steelhead/fish issue: Has this study looked at purchasing or building some massive fish canons to jetison the fish over the dams in a friendly, cost effective way? https://www.youtube.com/watch?v=iPuQ39iGkAY It seems the cost would be relatively tiny, compared to breaching the dams and trying to replace them. And the company that designed, engineers and produces them, Wooshh Innovations, is Washington-state based, http://www.environews.tv/081819-feat-of-engineering-salmon-cannon-explodes-across-internet-as-fish-get-free-flight-over-dams/	The co-lead agencies received additional comments related to use of water cannons, or similar proprietary adult fish passage devices. Currently, fish ladders are proven effective at moving adult fish upstream at the dams that have them. The technology of fish cannons or similar devices has demonstrated some success on smaller scales, and their use will continue to be evaluated for future applications.
2117	1	lightnerlarry@cableone.net	N/A	The total absence of input from some of the most significantly impacted elements, which includes sportsman and recreational and fishing businesses, makes it a totally pre-determined outcome without any credibility. This EIS should be redone taking into full account the input from these sources.	The EIS recognizes the value of the salmon fishing industry to the region. Section 3.15 describes the values associated with salmon fisheries in the Pacific Northwest. Section 3.11 characterizes the sportfishing economy in the region. However, the uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, limits a quantitative analysis of the specific impacts of each alternative on these values. The effects are therefore discussed qualitatively. The social welfare effects on fisheries under MO3 are described as major and beneficial in the long-term, with increases in regional economic effects if commercial fish catch rates increase. For the effects on recreational fishing under MO3 (Section 3.11.3.5), the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River). There is some uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. However, the EIS describes that the visitation in the long-term, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting recreation and tourism businesses. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For MO1, MO2, MO4, and the Preferred Alternative, the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.

2118	1	N/A	N/A	We have been spending increased amounts of money to facilitate fish migration. It would be interesting to me to see what we are spending per fish. I suspect that it is a large number, but have not seen it reported. The publication of such a number would allow the general public to understand the cost impacts in a fundamental way of many of these actions. I know that my power bills have greatly increased over the years as increased money have been spent on supporting fish migration. I wonder if alternative means couldn't supply fish at a lower cost. Stronger efforts to reduce consumption of juvenile fish by predators and additional fish hatcheries would seem to be a more cost effective efforts.	This CRSO EIS looked at alternative ways to operate, maintain and configure the 14 Federal projects. We looked at a variety of ways to improve fish passage and survival, with a wide range of benefits effects, which were a few of the main objectives of the EIS. Both No Action Alternative and the Preferred Alternative includes actions to reduce predation and would be carried out by the Federal agencies. It is not feasible to determine per fish the expenditures, as not all costs are accounted for fish by fish, but typically by habitat, health, and other variables.
2130	1	N/A	N/A	2. Create some sort of control mechanism on the numbers of seals that prey on the salmon; maybe a birth control drug that could be administered to the female seal, or the male.	Developing and administering birth control to seals is beyond the authority of the co-lead agencies and the scope of this EIS, which analyzes the effects of operation, maintenance, and configuration of the CRS projects. Regarding pinniped predation, sea lion management decisions at Bonneville Dam rely on input from the Sea Lion Management Working Group. This Working Group is a collaborative effort with NOAA, USFWS, various Tribes, and the co-lead agencies. The co-lead agencies works to minimize the effects of sea lions on salmon by implementing Best Management Practices specified in the NOAA Biological Opinion and by implementing recommendations developed by the Working Group. The co-lead agencies will continue to use this process to minimize the effects of sea lions on salmon within their authorities. The EIS discusses the Working Group and sea lion management in Section 3.5, 3.6 and Chapters 5 and 7.
2130	2	N/A	N/A	3. Work with the native americans in controlling the number of fish taken by nets, something like what you're doing with the numbers that non-native people may take in a given year. This could be achieved by a better fish counting method than what is presently being done on the netting harvest made by the native american.	For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and Tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., National Marine Fisheries Service), and Tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so.
2146	1	spangrudelaptop@q.com	N/A	The purpose of this submittal is to illustrate how long "fisheries issues," especially "declining salmon numbers" and "water temperatures above 68 degrees F" have been noted within the Pacific Northwest. One reference which provides interesting reading concerning fisheries as related to the Northwest United States is this item: Chapman, D.W. (1986). Salmon and Steelhead Abundance in the Columbia River in the Nineteenth Century, Transactions of the American Fisheries Society, 115:662-670. This reference shows graphically that the 'maximum Salmon Harvest' occurred in the 1880's; and has been in general decline since that time. This 'maximum harvest' occurred long before (80 years) the construction of the Lower Snake Projects in the early 1960's. Water temperature data was collected on the Lower Snake River from 1952 through 1956; which was therefore done under free-flowing conditions prior to the construction of the four Lower Snake River projects. The data collection results are summarized in United States Geological Survey (USGS) Water Supply Paper #1253 (for the year 1952), USGS Water Supply Paper # 1293 (for the year 1953), USGS Water Supply Paper #1353 (for the year 1954), USGS Water Supply Paper #1403 (for the year 1955), and USGS Water Supply Paper #1453 (for the year 1956). During this time, temperatures in excess of 65 degrees Fahrenheit were recorded on 304 days, which is approximately 17 per cent of the total observations, or about one out of every six made. Temperatures in excess of 70 degrees Fahrenheit were noted on 100 days, which is about 5 percent of the total observations, or about one out of every 20 made. In 2019, the Water Temperatures at three United States Geological Survey gaging stations located upstream of Lower Granite Project were generally above the 68 Degree F thresh hold since mid-July or early August 2019, depending upon the gage location. These monitoring points are the Salmon River at Whitebird (USGS 13317000), Snake River at Anatone (USGS 13334300), and the Clearwater River at Orofino (USGS 13340000). This current Water Temperature information is readily available online. Data was once available for the Snake River at Weiser (USGS 13269000) location as well; but unfortunately data collection was terminated due to 'loss of funding' after the 2015 Water Year; even though the year 2015 witnessed some water temperature issues downstream. Hopefully the Lower Snake River's extended picture will be addressed, both temporal and spatial aspects, as part of the decision making process. Declining fish numbers were noted long before the construction of the Lower Snake River Projects; and Water Temperatures exceeding 68 Degrees F are currently noted many miles upstream from these dams; and far removed from their direct influence.	The scope of the EIS focuses on the area affected by the alternatives presented for operation, maintenance, and configuration of Columbia River System Projects. This comment provides detailed information on the habitat area outside of the influence of the projects, as well as historical information. The EIS presents a brief description of the tributary habitat area and historical information as context, but it is not needed to be described in detail as none of the alternatives would result in changes to this habitat. It is noted that the temperatures historically contribute to challenges to salmon in the basin and that many factors have contributed to salmon declines, both before and after construction of the dams. The alternatives are evaluated in terms of change from the No Action Alternative, which is the baseline condition of 2016 when the development of the EIS began. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Sections 3.4 and 7.7.3 of the EIS.
2167	1	crcarlson@hughes.net	N/A	I write to you as a wheat farmer and as the President of the Oregon Wheat Growers League, where I represent our grower members throughout the great state of Oregon. Our growers overwhelmingly support the preferred alternative that rightly avoids the extreme measure of dam breaching. If the dams were breached, the clean power, irrigation supply, and navigable waters made possible by the federal system of locks and dams on the Snake River would come to an end and cause devastation. The demand on the remaining power grid would be stressed to supply inexpensive and reliable power to businesses, irrigated farms and local communities. The irrigation supply to Snake River farms and residential customers would be cut off and the demand from the remaining Columbia River dams would need to supply the deficit. Would there be enough reserves to fill the demand, or would those Snake River acres go back to desert without an inexpensive source of water?	The analysis of MO3 identifies impacts to power generation and reliability, navigation on the lower Snake River, and to irrigation. In Region C under the MO3 alternative this analysis concludes that pumps are unable to deliver water to estimated at 48,000 acres. There is a physical limitation to delivering water to these lands in the absence of the dams. Breach of the dams has the potential to drop surface and groundwater levels up to 100 feet and it is not possible from an engineering or cost standpoint to replace the delivery mechanisms, nor do the co-lead agencies have the authority to do so currently. Please see Section 3.12 and Appendix N for additional information.
2167	2	crcarlson@hughes.net	N/A	Without the Snake River Locks, the 3.5 million tons of cargo, normally shipped by barge, would be shipped by train and truck. It is estimated that it would take more than 35,140 rail cars to carry this cargo, or more than 135,000 semi-trucks. The rail and highway infrastructure along the Columbia River are not prepared to function with the loss of barging on the Snake River. In addition, our local wheat co-ops would have to make major capital investments in elevators and infrastructure to receive truck traffic from the Snake River areas. This would mean increased train loading and barge loading all along the Columbia River. The rail lines are almost at maximum capacity through the Columbia River system; rail, truck and barge rates will increase as demand increases, another cost our farmers will have to incur. The increased cost of trucking and rail, plus the put through cost at our local elevators will cause an economic hardship on farmers and co-ops who need to get the products to market economically. The increased transportation cost will heavily impact wheat producers who are already struggling to make ends meet on many accounts. Barging our wheat and other commercial products is not only the best option to support farm businesses, it is also the most environmentally friendly and safest mode of transportation available.	The Navigation and Transportation Section 3.10 reflects the adverse effects of implementing MO3 including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent). The EIS finds that average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are much higher, depending on their specific location and other conditions.
2191	1	smolts@msn.com	N/A	We can provide alternative technology strategies for the main obstacles the dams create for the anadromous salmon, which do not involve dam removal: (1) upstream migration, (2) downstream dam passage, and (3) slowed migration through the reservoirs. Each of these technology strategies involves the use of induced flows for fish guidance using our Flow Velocity Enhancement System (FVES) (Patten No.: US 6,729,800 B2). (1) Upstream migration by adult salmon can be aided by inducing flows in the reservoir forebay where salmon exit the fish ladder, thus reducing fallback. Cool, deep water can be directed at the exit in summer and fall where fish would be attracted to both the low temperature and the directional flow that they expect from a naturally flowing river. (2) Downstream dam passage can be aided by using the FVES to direct young salmon to a new bypass channel at each dam. These channels replicate a natural stream with all the features found in a stream. Newly constructed channels or nature-like bypasses would complement the existing gate-well collectors and save water for generation that is now spilled for fish passage. (3) The well-known slowing of migration through the impoundments, particularly in the dam forebays, that lengthens exposure times of fish to high temperatures and predators can be countered by inducing flow with FVES units. Induced flows can provide guidance in zones where fish lose contact with the directional-flow stimuli provided by natural rivers. Each of these proposed technology strategies is based on published scientific literature that is readily available. See, for example, chapters 6 and 7 by C. C. Coutant and R. R. Whitney in R. N. Williams, editor, Return to the River--Restoring Salmon to the Columbia River. Elsevier Academic Press, New York (2006). For important details about the NATURAL SOLUTIONS nature-like bypass, please see Patent No.: US 6,652,189 B2. We encourage you to explore with our firm how these strategies might be incorporated into a multi-faceted remedial program for improved salmon protection and propagation while retaining the important economic values of the four Snake River dams.	Thank you for your comment and additional information. The EIS recognizes that there are multiple ways that fish passage at dams could be replaced and relies on the current high quality information to identify improvements. We appreciate the insights in this comment regarding innovative project designs for replacing fish passage; however, information is limited to evaluate how effective these projects would be. The co-lead agencies received additional comments related to use of water cannons, or similar proprietary adult fish passage devices. Currently, fish ladders are proven effective at moving adult fish upstream at the dams that have them. The technology of fish cannons or similar devices has demonstrated some success on smaller scales, and their use will continue to be evaluated for future applications.
2200	1	zanbang@gmail.com	N/A	The draft EIS suggests that removal of the dams would have adverse social and economic effects and yet the document fails to recognize that salmon and orca whales are a critical part of the social and economic fabric of our society. The entire economy of the pacific northwest is rooted in salmon, as it has been since time immemorial. By lifting up the leadership of our local tribes we can and will learn how to live on this land more efficiently and peaceably.	The EIS recognizes the social and economic values associated with salmon although these values are not all expressed in monetary terms. Section 3.15 provides a discussion of the value of fisheries (commercial and subsistence) associated with salmon, as well as passive use values that people hold for these fish. Section 3.11 describes recreational values associated with the fish. Given uncertainty associated with the specific effects of the alternatives on overall fish abundance, these values are described qualitatively. Additionally, Section 3.17 provides information on the cultural significance of the salmon to regional Tribes. The analysis described in Section 3.6 of the EIS finds that MO3 will have a minor effect on the Southern Resident killer whales (see Table 3-106) and all other alternatives would have negligible effects on the species.
2200	2	zanbang@gmail.com	N/A	The drafters of this EIS state that breaching of the dams has an adverse impact of disallowing co-lead agencies to operate dams and this is not a stated objective of this document. This section should be removed as it is irrelevant to the stated objectives.	As stated in Chapter 2, the co-lead agencies developed alternatives to meet the objectives and the Purpose and Need. The Purpose and Need Statement includes a desire to meet the congressionally authorized purposes of the system, which include hydropower generation, inland navigation, and irrigation, among others. Each alternative was measured against the No Action Alternative in how well it could meet both achieve the objectives and meet the Purpose and Need Statement . Table 7-1 in Chapter 7 summarizes these considerations. Breaching of the four lower Snake River dams would adversely affect the co-lead agencies' ability to meet those congressionally-authorized purposes, as well as does not meet, or meet as well, the EIS objectives. Operations to meet these purposes are described in the No Action Alternative.
2200	3	zanbang@gmail.com	N/A	It is faulty logic to suggest that the power lost from the hydroelectric dams must be replaced with Natural Gas leading to increased GHG emissions. Washingtonians would never stand for this. This section should be amended to reflect the zero carbon options that are laid out in the EIS in lieu of the natural gas option.	The commenter is correct that the least-cost portfolio replaces lost power capacity with natural gas. The Draft EIS also includes analysis describing a zero resource portfolio, consistent with the commenters suggestion. Both least cost/natural gas and zero emission replacement portfolios were analyzed in the Draft EIS to provide a full range of costs and potential resource replacements. Additionally, by considering natural gas replacement, the conventional least-cost scenario employs an industry-standard approach to valuing changes in capacity. The basis for developing both of these portfolios is in Section 3.7.3.1, Methodology, of the Draft EIS.
2200	4	zanbang@gmail.com	N/A	The suggestion that archeological sites will be adversely impacted by breaching the dam is absurd. The archeological sites were drowned with the building of the dams. Giving this land back to the people who have used it for generations will improve their own connection with ancestors.	The co-lead agencies respectfully disagree that archaeological sites will not be adversely impacted by dam breaching. The co-lead agencies anticipate massive exposure and erosion increases in reservoirs during dam breach activities. As the analysis in Section 3.16.6 in the Draft EIS demonstrates, this would likely entail bank erosion, and in some cases, mass wasting events. Understandably, the erosion rate is dependent on local topography (slope) and geology (sediment structure), but is still expected to be highly impactful to the known and unknown archaeological resources in the areas that will be impacted by dam breaching activities. Other impacts would likely include gully erosion, increased looting, and other forms of ground surface disturbance. The co-lead agencies do agree that impacts to traditional cultural properties (TCPs) may decrease in the long-term in the areas impacted by dam breaching activities. Restoration to a more normative river would allow Tribal communities that attach importance to these traditional areas to access them once again. The overall impacts to TCPs from the dam breaching alternative is presented fully in Section 3.16.3.6 in the Draft EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
2202	1	elapsley@cableone.net	N/A	Lower dams generate about 1,000 Mw. Built in 1960s with tax payers money. EST life 50-100 years. Trojan plant was1,064Mw. Replacement 6B-9B. Who would buy replacement, tax payer. Who would pay remaining life of dams, Tax payer. Cost to rate payers for hydro electric is about $.85 c/kWh. Other sources are 50% or higher. Where is the value to the public?	The comment that replacing the four lower Snake River dams under MO3 will drive up costs in the region is consistent with EIS findings. Construction of the dams is paid for by customers of Bonneville, through the power rates Bonneville sets. Loss of the four lower Snake River dams would drive up costs to regional ratepayers regardless of whether Bonneville replaced the lost capability or regional (non-Federal) entities replaced the lost capability. See Draft EIS Section 3.7.3.5, Tables 3-166, 3-167. The average cost of generation from the Columbia River System is 8.5 cents/kWh (see Table 3-112, Draft EIS). The costs of other resources vary based on a range of other factors. Appendix H, Power and Transmission provides additional details on the selection of replacement resources and potential rate increases.
2203	1	cglanewman@gmail.com	N/A	Instead of removing the environmentally friendly dams, the focus should be placed on the other more lethal factors that affect salmon, such as gill nets from Indian tribes. Tribes did not have motor boats and gill nets when the treaties were signed in 1855, giving them the fishing rights they point to today when arguing this issue. The intent of the treaties, were to guarantee their traditional fishing methods to acquire food to consume... not harvest half of all the fish in the waters every year! The Nez Perce tribe is now placing gill nets in the Clearwater River upstream from Lewiston, ID and stocking the same river with lamprey eel to compete with the salmon for food and habitat. In the last 150 years, there has been a change of circumstance....	The co-lead agencies agree that there are many effects to salmon and steelhead populations other than the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm Fish harvest management is not within the scope and the co-lead agencies have no role or authority over fishing limitations or quotas. Fishing and harvest are subject to separate actions by federal, state, and tribal agencies outside the scope of this EIS.
2210	1	N/A	N/A	The issue are the predation in the Salmon Rivers and Tributaries due to Aggressive Brook Trout introduced in the CSRO System from the Eastern States - they do not migrate instead live in the Salmon, Snake and Columbia River System all the way to Montana - they move from one river system to another easily according to Wild Life studies but they are the largest predator from the Frank Church area and all three forks of the Salmon Rivers of Idaho and their tributaries. NOAA Studies of Juvenile Chinook Salmon Pit-tagged when they come from Valley Creek for example into the SALMON River and tracked to Lower Granite - 80-85% of them do NOT make it due to the slower moving, shallow areas of the Salmon River - the Fish Accords designated to all 4 states total $730 Million in 2014 - the Judge upon ordering this EIS designated $1.5 BILLION to HABITAT and Hatcheries in 2017 - THE EIS should show where that money went and how it was spent in the Federal U.S, State and Tribal Agencies - it has 3 years to be used for Habitat - Federal U.S. Forest Service, Federal Fish and Wildlife, Federal Bureau of Reclamation, Idaho, Washington, Oregon and Montana Wildlife and Game and the Tribes need to show what they did with the money given to them to actually restore Habitat for the Juvenile Fish so they can hide from the aggressive invasive species. Bull Trout are doing better but also pray on the Juveniles - which desperately need Habitat to hide in the Salmon River Forks.	The co-lead agencies agree predation is an important factor affecting salmon survival in tributaries before they reach Lower Granite Dam. The scope of the Draft EIS, however, focuses on the effects of the operations and maintenance of the CRS projects and none of the measures in the range of alternatives would affect brook trout or other predator populations in the tributaries. Regarding habitat funding, the requested information can be found in annual progress reports that detail the accomplishments under implementation of the 2008 Columbia Basin Fish Accords and Biological Opinions.
2210	2	N/A	N/A	Claiming non-applicable treaties is inappropriate - they are mislead. Multiple Acts made such as the Stevens and the Dawes Acts were directed to make all Native Americans citizens by 1924 and give each individual land - the 1855 Treaties and others had a 25 year life. The Constitution doesn't conflict with itself - Native Americans are eligible to run for offices in the U.S. Government - they still have to be a Citizen. We do not make treaties with U.S. Citizens. Tribes are Quasi Sovereign within the 4 corners of the Constitution and highly revered with great effort to restore their ability to have ceremonial fish forge a truly Trust Relationship Mutually. I want Native Americans Tribal members to receive more money designated to them directly instead it is eaten up through the BIA Bureaucracy - taking .75 cents to .90 Cents on the dollar - so their bitterness is understandable all big governments hurts their own people - a multitude of funds never make it to the individual members - but they must self determine to put an end to that. But the fight for the fish is a quandary - no one keeps track of exactly how many fish are taken as 1/2 per the Bolt Decision which many like me fully support - Orofino, ID they sell their rights to take people on guided tours - Openly. There does seem to be conflicting activities for these ceremonial fish. Factually and unfortunately, without bias The Fish Passage Center (a group of multiple tribes and confederated tribes from multiple states that directs the Technical Management Team re: the CSRO per Consultation - disobeyed the Judges Orders on two accounts from the 2014 Bi-OP - Sadly, they didn't follow the Judges Assigned Scientific Team who called on them to move the Juvenile Fish twice in Spring of 2015 - urging juvenile boiling alive to move them in March instead of May - they refused and only transported 13% rather than the Judge Order 40-50% - the same conditions occurred in 2001 and the Juvenile Fish were collected at each of the 4 Snake River Dams and Transported at 98% below Bonneville with cooperation from Fish Passage Center. The EIS should reflect and review the concerns around the man-made crisis not as a point of accusation but as a point of direct concern as to why then do the dams need to be torn down upon such events. From 1957 to 2015 - 25 years the Adult Fish Return Consistently increased from one year to the next year with the highest record number of Adult Returns in 2015 - contrast that to 2017 the year when the Adult returns that the 2015 Juveniles would have come back and confirmed catastrophic loss of 65% by a Man-Made Crisis - an Evidentiary Hearing was requested and the Judge swept it aside saying "He didn't want to hear 'old business' "to man-made crisis that was unprecedented and shouldn't have happened - he also quipped with smile out loud that we might have to breach/do deep draw downs on the Snake River Dams" - DEEP DRAW DOWNS are the SAME affect and result and unnecessary. $1.5 BILLION was designated and where did it go? Tribes don't seem to be anti-dam they studied dams per the Native American Energy Act and their best Opportunity upon review from Alaska to California was the Lower Snake River Dams from 2014-2017. Wouldn't that mean they want the dams and the fish to succeed - if so what changed? The final draft of the EIS needs to answer this. While the EIS has to consider our Native American Neighbors - the Consultation with them failed in Spring 2015 - after decades of protocol and the Judges orders under the Spread the Risk program 50% In-river and 50% Transport to assure Salmon would return and every year transport was used - the fish came back in consistent numbers as a proven method - now the dams are on the chopping block - they and us have to both be bilaterally responsible with one another - that means help, understanding and accountability one to another - peacefully and work together.	The CRSO EIS evaluated alternative plans for operation, maintenance and configuration of the system. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Analysis shows that the Preferred Alternative would meet the objectives for improving juvenile salmon, adult salmon, resident fish and lamprey. The analysis found ranges in potential effects due to different assumptions included in each of the fish models used in the study. Using the Comparative Survival Study (CSS), Snake River Chinook salmon and steelhead are expected to see relative improvements in smolt-to-adult returns of 35 percent and 28 percent, respectively. The Smolt-to-Adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While achieving long-term recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. If latent mortality effects are reduced by passing more juvenile fish through the spillway, the NMFS Lifecycle Model (LCM) also shows that levels of SARs would increase. However, if latent mortality effects are not reduced, or are different than modeled, the LCM predicts that SARs for Snake River spring Chinook salmon may be lower than the No Action Alternative (a range of -7.5 percent to +28 percent change relative to the No Action Alternative) due to reduced opportunities for fish transportation. Results for upper Columbia River stocks are beneficial based on LCM estimates. In-river survival and SARs are anticipated to increase. The CSS model does not currently model upper Columbia fish. The Preferred Alternative also has measures intended to increase upstream passage success and reduce injury and mortality for Pacific lamprey. These measures are proposed structural improvements that include converting extended-length submersible bar screen material to screen material that would not impinge or entangle juvenile lamprey, expanding the network of lamprey passage structures to bypass impediments in fish ladders, changing the design for turbine cooling water strainers, and replacing turbines for safer fish passage. The Preferred Alternative would also meet the objective to improve resident fish. Effects to resident fish vary by region and species, but are generally minor relative to the No Action Alternative.
2210	3	N/A	N/A	All three modes of Transportation are required during harvest to transport the wheat to the port for sale - if the wheat and other products don't make it on time - no sale. The stakeholders meetings repeatedly made it clear the rail system was not adequate to handle transport adequately the wheat produced. And the Clean Air Act would be drastically affected by 40,000 additional rail cars or 174,000 additional semi-trucks.	The Navigation and Transportation Section 3.10 reflects the adverse effects of implementing MO3 including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportaton infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent).
2210	4	N/A	N/A	The Clean Water Act Model exaggerated water temps 20% in their model - WA Policy Center met with NOAA and went through the same data Empirically and proved the model WA Dept. of Ecology and the Fish Passage Center collaborated or were drawn to collaborate on by Dept. of Ecology of WA State.	Thank you for your comment. The EIS describes the water quality modeling used for this analysis in Section 3.4.
2221	1	wjperconti@lcsc.edu	N/A	Why not consider this compromise: Is it possible to modify the dams into wing dams? Such a modification may allow fish passage while harvesting water for storage and energy.	In order to maintain authorized purposes for hydropower generation and navigation, a number of new wing dams would need to be constructed in the rivers (in addition to the existing dams) to maintain depths for navigation. Wing dams could potentially require significant modifications to the powerhouses to adjust to changed head on the reservoirs. Both would require extensive construction and modification efforts, and would be similar in adverse effect to navigation, water supply and irrigation, and power reliability as MO3. As the co-lead agencies operate the system for much broader purposes as identified in the Purpose and Need Statement, wing dams were not considered a reasonable alternative, and therefore not considered in addition to dam breaching structural measures or other operational management measures.
2226	1	ecopenhaver@bentonrea.org	N/A	I am confused by the two models used in the study to determine fish survival rates after the highest spill levels. Because they don't agree, I don't have confidence that higher spill over the dams will help fish survival. Higher spill prevents electricity from being generated, and since there's no guarantee it will help the fish, why do it?	The co-lead agencies used the two models approaches - CSS and NMFS' Life Cycle models - in its analysis of the range of alternatives because they are the models routinely utilized in this region to provide high quality information and best science. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored and effects from other sources such as harvest, ocean mortality, and straying will also be accounted for to the extent possible.
2237	1	frank.lawson@eweb.org	N/A	While the CRSO-DEIS is a crucial piece of that bigger picture, consideration of elements outside the scope of the Draft EIS is also required. For example, the overall recovery and wellbeing of Columbia Basin salmon and steelhead runs is dependent on considerations beyond just the dams. In seeking to mitigate the adverse impacts of the CRS to anadromous fish populations, it is essential that we fully account for the many stressors contributing to these impacts, including urbanization, development in floodplains, nonpoint source pollution, climate change, ocean conditions, and avian predation.	The co-lead agencies concur with the commenter that there are multiple stressors on the environment that adversely affect regional salmon populations. The co-lead agencies also recognize that there are many effects to salmon and steelhead populations outside the operation of the dams. The co-lead agencies acknowledge there are many factors that affect salmonid populations that are outside the authority of the co-lead agencies. Both human-caused and natural factors that are outside the responsibility and control of the co-lead federal agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. The effects analysis in Chapters 3, 4, 6 and 7 evaluates the direct, indirect and cumulative effects to resources affected by CRS operations, maintenance and configuration. These chapters take into consideration the existing environment, which includes the stressors mentioned by the comment, among others, and evaluates the contribution of effects associated with any proposed changes. Additionally, the scope of the EIS allowed the agencies to focus on the effects of the co-lead agencies actions combined with other on-going actions and trends to determine the direct, indirect and cumulative effects to resource as well as the contribution of benefits. For additional information, see Chapter 6 and Chapter 7 for a discussion of cumulative effects, including the past, present and reasonably foreseeable future actions that also impact resources affected by the CRS.
2237	2	frank.lawson@eweb.org	N/A	EWEB is supportive of the CRSO-DEIS as a transitional guiding policy. We believe the Preferred Alternative will improve beneficial fish outcomes, including reductions in Powerhouse Encounter Probabilities and an increased Smolt-to-Adult Returns (SAR) ratio. Further, it seeks to harmonize fish benefits and power benefits to the greatest extent possible until other long-term options can be explored and/or developed. Of particular interest to EWEB, and what we consider an important part of the CRSO-DEIS, is the Flexible Spill concept strategically increasing spill when hydropower demand and value is lower and reducing spill when hydropower demand and value is higher.	The commenter's suggestions about outcomes of the Preferred Alternative are consistent with the findings of the EIS. The Flexible Spill concept has been integrated into the Preferred Alternative, as described in Chapter 7.
2241	1	N/A	N/A	The report that was done for this did not even mention the cost of having little to no fish return. I think leaving out that bit of information shows the one track mind that was put into this report. And the reason it was left out is because it would overwhelmingly show that the benefit of removing the damns would far out weight the costs.	NEPA does not require a hypothetical condition as a point of comparison, such as a world with little to no fish or "worst case scenario." NEPA requires a comparison of proposed alternatives to the No Action Alternative with a description of effects compared to the existing conditions.
2242	1	spauley4@gmail.com	N/A	Why has everyone forgotten the 2002 study by the Rand Corp on dam removal? The conclusions were that breaching the 4 lower Snake dams would not cause economic harm to the northwest and was the best way to save salmon and steelhead. Breaching would create new jobs. The powers at hand should dig out this study. The Rand Corp is a conservative group that researches subjects in depth. Wind and solar have made great progress. Why	The EIS acknowledges previous analyses of breaching the four lower Snake River dams. However, the EIS relies on current information to evaluate the tradeoffs associated with dam breach under MO3. This includes applying current models and data rather than relying on findings from studies conducted nearly 20 years ago. Further, please see Section 3.7.3.5, Social And Economic Effects Of Changes In Power And Transmission, for a discussion of the regional retail rate effects of dam

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				ignore that? Why continually go back to go over the same things year after year? The Army COE also said in past studies that breaching is the best solution to saving the fish from extinction.	breaching. As described in that section, the general impacts of breaching the four lower Snake River dams is to increase the rates of most consumers of energy in the region, which has the potential to have the highest impact on rural areas. Higher retail rates means less spending on production, which reduces job growth. See Table 3-175 for the regional economic effects from changes in household spending on electricity.
2248	1	gaffco70@icloud.com	N/A	Commerce/transportation on the river barges would be lost. This would immediately allow the railroads to greatly increase rates due to loss of competition. They also are already heavily burdened, at this would slow down freight transport even more. 2. The loss of grain (and other items) transport on the river system would also mean many more trucks on our roads, causing more pollution and greatly increased road wear and tear	The Navigation and Transportation Section 3.10 reflects the adverse effects of implementing MO3 including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent).
2260	1	David Dunkelbury	Kenney Farms, Inc.	Over a period of nine months in 2017, more than 3.5 million tons of cargos were barged on the Snake River. It would have taken more than 35,140 rail cars to carry this cargo, or more than 135,000 semi trucks. There is insufficient infrastructure to accommodate this kind of increase in truck and rail traffic. It would increase in emissions, increase the number of rail and vehicle accidents, including fatalities and would require further investments into infrastructure and additional road repairs which both states cannot afford.	Section 3.10 of the Draft EIS provides an evaluation of the Columbia-Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, and low air emissions relative to other transportation modes. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. Under low rail rate increase scenarios, additional shortline rail capacity would be required that could cost $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear and tear costs may occur. The EIS finds that average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled, depending on their specific location and other conditions.
2266	1	Roger Gray; R Stark	PNGC Power	This is actually an information request and series of questions about the DEIS that will help us prepare our formal comments. If I need to submit these questions as comments on the DEIS, please let me know. PNGC Power plans to submit comments by the April 13th deadline. My questions pertain to the LOLP calculations and figures contained in the DEIS. Specifically, I am looking for more information about MO3 and MO4. The LOLP in the NAA (i.e. "basecase") is 6.6%. The LOLP for MO3 is 13.9% (rounded to 14% elsewhere in the DEIS). The LOLP for MO4 is 30%. If the questions are unclear, please contact me on the phone number or email provided. Usually, LOLP studies run multiple scenarios and then the LOLP is the percent of scenarios that fail to meet load. I was wondering if the Co-lead agencies could provide the following pieces of information (or information that most closely gets at the underlying request. 1. How many scenarios were run for NAA and each MO? Is there a general summary of scenarios (winter-dry, winter-wet, cold winter-dry, etc. etc.)? 2. Confirm (or correct) this statement: For MO3 and MO4, the LOLPs of 14% and 30% were based on the reductions in power supply (e.g. dam breaching or spill) with no other changes to the underlying power system. 3. Were LOLPs run for MO3 and MO4 after the replacement resources were put back in the model? The two sets are replacement resources proposed are: (i) zero-carbon portfolio and (ii) conventional least cost portfolio. If so, what were the LOLP results for MO3 and MO4 after the replacement resources were put back in? 4. For LOLP results in MO3 and MO4 (the 14 and 30% results, respectively), did the scenario analysis and results also produce Expected Unserved Energy (EUSE) or Energy Not Served (ENS)? What were the peak magnitude (MW) and duration (hours) of such unserved energy and total EUSE/ENS (MWH)? Since scenarios typically produce different figures for MW, duration and MWH, if actual data is available for each scenario that would be ideal. Otherwise, I'd appreciate summary data that includes: min, max, mean and average EUSE/ENS. 5. Did the co-lead agencies attempt to quantify or monetize the societal cost of EUSE or ENS? If so, what were the results and what were the underlying methodologies used (e.g. VOS or VOLL?). Thank you Roger Gray PNGC Power ps: I'd suggest that a box for "Power Supply/Reliability" be added to the "Areas of Concern" boxes below. I checked "other" for now.	Chapter 4 of Appendix J, System Reliability, and Chapter 2 of Appendix H, Power Supply and Replacement Resources, provide additional details on the power reliability analysis and LOLP modelling. In response to the commenter's five questions and clarifications: 1) The LOLP analysis is the result of 6,160 simulations. The EIS does not contain a full accounting of all scenarios; however the scenarios and load forecasts are consistent with Northwest Power and Conservation Councils Power Supply Adequacy Assessment. 2) The commenter is correct, LOLP was run for all MOs prior to including any replacement resources. The cited LOLPs for MO3 and MO4 solely reflect changes in hydropower generation. 3) The amount of replacement resource required under each scenario was analyzed to reduce LOLP to the No Action Alternative level (6.6%) for all MOs. 4) The EIS analyzed Conditional Value at Risk (CVaR), which evaluates the amount of monthly average energy not served in the worst 5 percent of LOLP simulations. Chapter 4 of Appendix J summarizes the CVaR results. The EIS did not analyze EUSE. 5) The CVaR results were quantified but were not explicitly monetized beyond the value of the replacement resources identified to reduce LOLP to the No Action Alternative level.
2268	1	commcomm2@gmail.com	N/A	I am requesting you please add an extension to the comment period due to Covid-19!	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
2270	1	luke.henkel@gmail.com	N/A	There is even more danger now that an assessment will be skewed and made more difficult by cuts--an overall "gutting"--of NEPA, the National Environmental Protection Act, from the current administration. This is unconscionable.	The co-lead agencies have conducted the NEPA process as required by the Act and the existing implementing regulations.
2270	2	luke.henkel@gmail.com	N/A	Money will not be relevant if we do not have thriving biodiversity and abundance of life. An example of a study in 2015 conducted by Anthony M. Jones of the Boise economic consulting firm Rocky Mountain Econometrics: "farmers who use the river instead of rail save about 2.4 cents per ton, or about $7.6 million annually. But he said the Army Corps of Engineers spends $17.8 million per year to maintain the river transportation system and hundreds of millions each year to mitigate the harm dams cause to fish." Are we going to let money be the ultimate factor in deciding what we do moving forward? I sincerely hope not! I know we must look at economics--it's difficult not to.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The EIS estimates the costs to operate the CRS dams, as well as the costs to the navigation and transportation industry that would be occur if the lower Snake River dams are breached under MO3 as part of this broad analysis that aims to balance the objectives of the agencies for the system.
2274	1	Jeff Anderson; salem electric	Salem Electric	We believe that breaching the four lower Snake River dams would have an adverse impact on electric cooperative consumers, the reliability of the Northwest energy grid, and the global environment. The Snake River dams are an integral part of our electricity supply in the Pacific Northwest, powering 900,000 homes annually. Oregon's electric cooperatives are serious about our mission of delivering clean, affordable, reliable electricity to our members. The DEIS concluded that breaching the Snake River dams would have "long-term, major, adverse effects on power costs and rates," and the "rate pressure could be up to 50% on wholesale power rates." A 50% increase in BPA's rate could lead to an increase of several hundred dollars a year for electric cooperative consumers. The most impacted by these rate increases will be our vulnerable populations seniors and those on fixed incomes - who shouldn't have to choose between medicine, food, or paying their electric bills.	The comment that replacing the four lower Snake River dams under MO3 would drive up costs in the region is consistent with EIS findings. The Environmental Justice analysis in Section 3.18.3 of the EIS provides further detail on potential disproportionate effects including to Tribal, low-income and minority populations for MO3. Chapter 5 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers.
2274	2	Jeff Anderson; salem electric	Salem Electric	We also should reject any proposal that will lead to blackouts. The DEIS concludes the dam breaching alternative would "more than double the region's risk of power shortages." The Pacific Northwest has a legacy of clean energy but according to the DEIS, breaching the dams would create a 10% increase in power-related emissions across the Northwest.	The commenter is correct that without replacement power, MO3 which includes the measure to breach the four lower Snake River dams, would increase the frequency of power shortages. If the lost capability of the four lower Snake River dams is replaced with natural gas, as assumed in least-cost conventional resource portfolios, emissions would increase. The EIS also considered replacing the lost capability of the four lower Snake River dams with a zero-carbon resource portfolio. The zero-carbon resource portfolio consists entirely of zero carbon resources: solar, wind, and storage technologies (i.e., batteries). However, even with new renewable resources, the EIS analysis finds that existing carbon-emitting resources would likely increase generation to integrate the large portfolio of renewable resources, resulting in a net increase in greenhouse gas emissions. This portfolio is described in Section 3.7.3.5, Potential Replacement Resources and Associated Costs, and emissions implications in Section 3.8.3.5, Greenhouse Gas Emissions from Power Generation in the Draft EIS. The measure to breach the four lower Snake River dams that was evaluated in MO3, was not included in the Preferred Alternative identified in the Draft EIS. The effects of the Preferred Alternative on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the Preferred Alternative. However, because of the shape of the remaining hydropower generation in the Preferred Alternative, the loss of load probability was essentially the same as that of the No Action Alternative.
2279	1	mcarrasco98@gmail.com	N/A	You need to extend the public comment to well after the corona virus pandemic is over with. Public meetings are needed, not just teleconference which limits participation and a great deal of time is necessary to submit public comments on a draft this large. I could go on and on, but I think you get the idea.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
2296	1	N/A	N/A	The Preferred Alternative in the Draft EIS does not adequately provide for salmon and steelhead populations because it will not improve smolt to adult turn rates (SARs) to levels identified by scientists as necessary for harvest or recovery. Harvestable populations need a SAR around 4%, meaning 4 adults return for every 100 juvenile fish that head to the ocean. Under the Preferred Alternative, SARs for Snake River spring Chinook will reach 2.7% at best. The predicted SAR is even lower for Snake River steelhead at 2.4%. At worst, The Life Cycle Model predicts an extinction trajectory under the Preferred Alternative with a SAR below 1%.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. It should be noted that the 4% average SAR target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on our analysis in the Fish resources section of Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is predicted to benefit salmon and steelhead. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy. The CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
2296	2	N/A	N/A	The Draft EIS did not take into account the economic impacts of the Northwests salmon fishing industry. When evaluating the economic impacts of each alternative, the analysis completely ignored the sportfishing economy and its estimated contribution of over $757 million in Idaho alone (over $2 billion region-wide).	The EIS recognizes the value of the salmon fishing industry to the region. Section 3.15 describes the values associated with salmon fisheries in the Pacific Northwest. Section 3.11 characterizes the sportfishing economy in the region. However, the uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, limits a quantitative analysis of the specific impacts of each alternative on these values. The effects are therefore discussed qualitatively.
2296	3	N/A	N/A	The Draft EIS relied on a qualitative, rather than quantitative, analysis to evaluate impacts despite the existence of several current studies on the economic contributions of outdoor recreation and sport fishing in states with salmon and steelhead. This is in contrast to water supply, irrigation, navigation, and hydropower generation, which were all evaluated quantitatively. It is unacceptable that the Draft EIS did not use publicly-available data sources to quantify the devastating financial impacts of declining salmon and steelhead populations on rural communities in Idaho and the Pacific Northwest.	The EIS recognizes the value of recreational and commercial fishing to the region. Section 3.15 describes the values associated with fisheries in the Northwest. Section 3.11 characterizes the sportfishing economy in the region. However, the uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, limits a quantitative analysis of the specific impacts of each alternative on these values. The effects are therefore discussed qualitatively. The social welfare effects on fisheries under MO3 are described as major and beneficial in the long-term, with increases in regional economic effects if commercial fish catch rates increase. For the effects on recreational fishing under MO3 (Section 3.11.3.5), the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
2300	1	adeleriffe@yahoo.com	N/A	While the science shows that increased levels of spill can buy some additional time to put in place more effective actions for imperiled fish populations, it is not, by itself, a long-term survival strategy, let alone a recovery strategy. Indeed the parties to the current, short-term Flexible Spill Agreement made this explicit and respected regional scientists have confirmed that the flexible spill included in the Preferred Alternative will NOT deliver salmon the survival benefits through the hydrosystem they need. The changing climate will further erode any benefits of flexible spill as a long-term approach and only underscores the urgency for meaningful action.	As required by NEPAs implementing regulations, the co-lead agencies used the best available information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. There are many factors that contribute to salmon and steelhead populations including changes to ocean conditions, predation, harvest, etc. The analysis in this study, particularly relating to the fish passage spill operation, focus on the migratory impacts to salmon and steelhead from the operations of the Columbia River System projects. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Based on our analysis in the fish resources section of Chapter 7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call however is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
2302	1	onboardtours@yahoo.com	N/A	I am requesting an extension to the comment period. Given the fact that there will be no public meetings and there is so much concern and attention on the COVID-19 situation, the public will need more time to read and comment on this important issue.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
2303	1	justismclaren@gmail.com	N/A	Because of the world (and particularly our little place in it) being so heavily affected by the COVID-19 pandemic, it is imperative that you give the proper chances for the public to learn about this proposal and be allowed time to consider it and comment. The right thing to do is to extend the deadline for comments - this should not be rushed through under cover of a virus when people are concerned about their families, jobs and homes.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
2309	1	srichard@colrip.com	N/A	Look at the Snake River historical return (provided). It's amazing that Chinook salmon were able to recover from the 1980's grim returns. The 1980's average return was a fraction of even 2019's. But recover they did. We did and are doing something right. I do agree that the current decline is concerning. The ray of hope is that the trend appears to have bottomed. Are the Snake River dams to blame? Could it be ocean acidification? A warming Earth? More sealions in the river than I've ever seen? Ironically, just 5 short years ago we experienced an (at least 40 year) record return of Fall Chinook. It's not a coincidence that Lower Columbia tributaries are following the same graph line.	We agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm
2309	2	srichard@colrip.com	N/A	Many questions remain: How will we realistically replace the power generation with anything even nearly as non- polluting.	The commenter is correct that breach of the four lower Snake River dams would increase emissions from power generation (see Section 3.7.3.5 in the Draft EIS). The EIS also considered replacing the lost capability of the four lower Snake River dams with a zero-carbon resource portfolio. This portfolio is entirely made up of zero carbon resources (solar, wind, storage technologies [e.g., batteries]). However, even with new renewable resources, the EIS analysis finds that existing carbon-emitting resources would likely increase generation to integrate the large portfolio of renewable resources, resulting in a new increase in greenhouse gas emissions. This portfolio is described in the Draft EIS in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, and emissions implications in Section 3.8.3.5, Greenhouse Gas Emissions from Power Generation.
2309	3	srichard@colrip.com	N/A	Will farmers even be able to produce a crop without the current access to irrigation water? What will happen to the thriving Columbia River maritime and export economy that depends on river transportation? What about the commitment to the cities of Lewiston, Id and Clarkston, Wa and Almota, Pomeroy, Wind Dust or Central Ferry to the promise of access to navigation?	The potential economic effects from breaching of the lower Snake River dams are presented in the EIS, organized by resource area and type of economic effect, with additional details provided in resource specific appendices. Economic effects are described for Navigation and Transportation (Section 3.10) and Water Supply (Section 3.12). Potential economic effects are evaluated for social welfare effects (national economic effect), regional economic effects and other social effects. Additionally, the environmental effects associated with increased emissions to shipping goods by rail or truck (or both) are evaluated and described in the Air Quality Section (3.8), and increased health and safety concerns are described in the Navigation and Transportation Section for other social effects (Section 3.10.3.5). Breach of the dams has the potential to drop surface and groundwater levels up to 100 feet and it is not possible from an engineering or cost standpoint to replace the delivery mechanisms, nor do the co-lead agencies have the authority to do so currently. Assumptions regarding the cost of reconfiguring water supply systems are discussed in the Water Supply Environmental Consequences Section for MO3 (Section 3.12.3.4, Region C). Effects to livelihoods are captured to the extent possible in the regional economic effects and other social effects sections that follow. Please see Section 3.12 and Appendix N for additional information.
2319	1	N/A	N/A	Without hydroelectricity to fill in the gaps, the grid cannot take the swings in generation caused by fluctuations in wind and sunshine. The Northwests demand for electricity is highest in the winter when wind is less prevalent and the sun sets early. The dams provide affordable electricity – Several independent studies indicate a shortage of electricity generation in the coming years, particularly with the closure of coal plants. The lower Snake River dams are critically needed to avoid a repeat of the 2000-2001 energy crisis that resulted in soaring electricity prices. The draft EIS indicates that replacing lost generation from dam removal with carbon-free resources could result in a 50% increase in power costs. That doesnt consider the loss of coal generation which will also need to be replaced by carbon-free resources to reach CETA goals. A rise in energy costs would worsen our homeless crisis and mean greater hardships for people already struggling to make ends meet.	The comment that replacing the four lower Snake River dams under MO3 would drive up costs in the region is consistent with EIS findings. The Environmental Justice analysis in Section 3.18.3 of the EIS provides further detail on potential disproportionate effects to Tribal, low-income and minority populations under MO3. Chapter 5 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers. The ability of hydropower to aid in grid stability and the integration of renewable power is described in the Bonneville Transmission System Reliability and Operations subsection of Sections 3.7.3.3 through 3.7.3.6 and in Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the Draft EIS.
2329	1	N/A	N/A	The dams provide affordable electricity. Several independent studies indicate a shortage of electricity generation in the coming years, particularly with the closure of coal plants. The lower Snake River dams are critically needed to avoid a repeat of the 2000-2001 energy crisis that resulted in soaring electricity prices. The draft EIS indicates that replacing lost generation from dam removal with carbon-free resources could result in a 50% increase in power costs. That doesn't consider the loss of coal generation which will also need to be replace by carbon-free resources to reach CETA goals. A rise in energy costs would worsen our homeless crisis and mean greater hardships for people already struggling to make ends meet.	The comment that replacing the four lower Snake River dams under MO3 would drive up costs in the region is consistent with EIS findings. Likewise, the connection between reducing carbon emissions (under CETA and coal-plant retirements) is discussed in the EIS. The Environmental Justice analysis in Sections 3.18.3 and Chapter 7 of the EIS provides further detail on potential disproportionate effects to Tribal, low-income and minority populations under the Multiple Objective Alternatives and the Preferred Alternative, respectively. Chapter 5 of Appendix H, Power and Transmission provides additional details on potential rate increases by county as well as for urban and rural utility customers.
2329	2	N/A	N/A	The dams are just one factor in salmon and orca survival. Salmon from the Snake River are only one part of an orca's diet. Salmon survival rates through these dams are as high as 97%. NOAA Fisheries' analysis shows Puget Sound Chinook salmon are most important for the Southern Resident Orcas. Cleaning the Puget Sound and removing sea lions would be a better use of time and money in saving our treasured salmon and orca.	The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Regarding Puget Sound conditions, the effects mentioned in the comment involve a variety of issues beyond the scope of the CRS project. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
2335	1	vern2dkv@gmail.com	N/A	Sec. 1.8, Line 666 The following documents should be added to the list of key relevant documents because these documents contain the recovery goals for the Snake River salmon and steelhead species. These recovery goals are applicable for alternative evaluation. U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service, ESA Recovery Plan for Snake River Spring/Summer Chinook Salmon (Oncorhynchus tshawytscha) & Snake River Basin Steelhead (Oncorhynchus mykiss), November 2017. U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service, ESA Recovery Plan for Snake River Sockeye Salmon (Oncorhynchus nerka), June 8, 2015. U.S. Department of Commerce, National Oceanic and Atmospheric Administration, National Marine Fisheries Service, ESA Recovery Plan for Snake River Fall Chinook Salmon (Oncorhynchus tshawytscha), November 2017.	The recovery plans noted in the comment were included in the CRSO EIS analysis. The actions included in the recovery planning reports published by NMFS under ESA Section 4(f) guide the actions of both Federal and non-Federal parties. The actions identified under the recovery planning documents are generally consistent with the actions analyzed in this NEPA analysis.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
2337	1	vern2dkv@gmail.com	N/A	Sec. 2.1, Line 23-24 The first sentence should be modified as follows: The MOs include a range of spill levels for juvenile fish passage, varying levels of hydropower production, and differing actions to support the needs including recovery of Endangered Species Act (ESA)-listed anadromous and resident fish. This change is needed because the temporal scope of the EIS is 25 years. The past 50 years of investment for anadromous fish has not led to recovery of the fish. In 2019, salmon and steelhead returns were significantly below recovery goals for Snake River endangered salmon and steelhead. The amounts are dramatic regarding the recovery of these fish. Sockeye returns were 97% below recovery goals. Fall chinook was 76% below recovery goals. Spring/summer chinook returns were 70% below recovery goals. While steelhead were a dismal 66% below recovery goals. Another 25 years without achieving recovery goals will likely cause significant adverse impacts upon the Snake River anadromous fish and potential extinction unless recovery is addressed in the Columbia River System Operations EIS.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on our analysis Fish resources section of Chapter 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets most of the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
2338	1	vern2dkv@gmail.com	N/A	Sec. 2.2.1 Objective 2, Line 73 Objective 2 should be modified as follows: Achieve recovery goals for ESA-listed anadromous fish within the CRSO project area through actions including but not limited to project configuration, flow management, spill operations, hatcheries, and water quality management. This change is needed because the temporal scope of the EIS is 25 years. The past 50 years of investment for anadromous fish has not led to recovery of the fish. In 2019, salmon and steelhead returns were significantly below recovery goals for Snake River endangered salmon and steelhead. The amounts are dramatic regarding the recovery of these fish. Sockeye returns were 97% below recovery goals. Fall chinook was 76% below recovery goals. Spring/summer chinook returns were 70% below recovery goals. While steelhead were a dismal 66% below recovery goals. Another 25 years without achieving recovery goals will likely cause significant adverse impacts upon the Snake River anadromous fish and potential extinction unless recovery is addressed in the Columbia River System Operations EIS.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The co-lead agencies will continue to fund conservation and safety net hatcheries. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets most of the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
2339	1	vern2dkv@gmail.com	N/A	Sec. 2.4, Line 156 The Columbia River System Operations Environmental Impact Statement completely disregards the mission of Governor Littles Salmon Work Group. The mission of the work group is to develop policy recommendations for Governor Little through a collaborative, consensus driven, public process to restore abundant, sustainable, and well distributed populations of salmon and steelhead in Idaho for present and future generations, while recognizing diverse interests throughout the State. The Environmental Impact Statement does not evaluate Snake River Specific Alternatives. The Columbia River System Operations Environmental Impact Statement should be modified to develop and evaluate Snake River specific Alternatives. The Snake River specific alternatives need to address restoring abundant, sustainable, and well distributed populations of salmon and steelhead in Idaho for present and future generations	As stated in Chapter 2, the co-lead agencies developed alternatives to meet the objectives and the Purpose and Need. The Purpose and Need Statement includes the need for action as well as the resource and legal and institutional purposes. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The co-lead agencies did analyze two alternatives, MO3 and MO4, that were directly related to the Snake River salmon and steelhead survival through the migration corridor, which could be used as part of Governor Little's Salmon Work Group.
2340	1	vern2dkv@gmail.com	N/A	Sec. 2.4.3 Line 1188, p. 2-37 Under Structural Measures in Table 2-4, add a new structural measure to construct additional anadromous fish hatcheries upstream of Lower Granite Dam in Idaho to achieve recovery goals. This change is needed because the temporal scope of the EIS is 25 years. The past 50 years of investment for anadromous fish has not led to recovery of the fish. In 2019, salmon and steelhead returns were significantly below recovery goals for Snake River endangered salmon and steelhead. The amounts are dramatic regarding the recovery of these fish. Sockeye returns were 97% below recovery goals. Fall chinook was 76% below recovery goals. Spring/summer chinook returns were 70% below recovery goals. While steelhead were a dismal 66% below recovery goals. Another 25 years without achieving recovery goals will likely cause significant adverse impacts upon the Snake River anadromous fish and potential extinction unless recovery is addressed in the Columbia River System Operations EIS.	Additional fish hatcheries were not included in the original construct of the Multiple Objective Alternatives, which focused on addressing eight objectives and measures for changing the operations, configurations, and maintenance of the 14 CRS projects. Hatcheries and the need for additional output was considered by the co-lead agencies and cooperating agencies during identification of mitigation actions for each alternative. Only MO3 was determined to need additional hatchery production for the short term impacts from breaching the four lower Snake River dams. Additional hatcheries were not identified as needed for mitigation under any alternative. See Chapter 5 for discussion of mitigation. However, the co-lead agencies will continue to fund existing conservation and safety net hatcheries under the Preferred Alternative. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. With respect to the Preferred Alternative, fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals.
2341	1	vern2dkv@gmail.com	N/A	Sec. 2.4.3, Line 1319, p. 2-42 Additional column should be added to Table 2-5 to address the effects of the spill test on adult Snake River anadromous fish such adult to smolt ratio or similar criteria. Additional analyses are needed for these additional criteria. The information on p. 3-251 (Lines 5485 5490) indicates that water quality standard excursions are expected to continue. Thus the spill test is likely to increase the number of excursions. That information suggests the spill test is not beneficial and should be eliminated from the alternative analysis.	Effects of the various alternatives on fish resources, including SARs, are discussed in detail in Section 3.5. The spill test will result in increased TDG in the lower Snake and Columbia rivers. Monitoring is planned to assess impacts to fish. The goal of the spill test is to evaluate the benefits to downstream fish passage resulting from increased spill and impacts to fish from TDG, potential impacts to passage, and other potentially harmful effects on fish.
2342	1	vern2dkv@gmail.com	N/A	Sec. 2.4.4 Line 1540, p. 2-49 Under Structural Measures in Table 2-6, add a new structural measure to construct additional anadromous fish hatcheries upstream of Lower Granite Dam in Idaho to achieve recovery goals. This change is needed because the temporal scope of the EIS is 25 years. The past 50 years of investment for anadromous fish has not led to recovery of the fish. In 2019, salmon and steelhead returns were significantly below recovery goals for Snake River endangered salmon and steelhead. The amounts are dramatic regarding the recovery of these fish. Sockeye returns were 97% below recovery goals. Fall chinook was 76% below recovery goals. Spring/summer chinook returns were 70% below recovery goals. While steelhead were a dismal 66% below recovery goals. Another 25 years without achieving recovery goals will likely cause significant adverse impacts upon the Snake River anadromous fish and potential extinction unless recovery is addressed in the Columbia River System Operations EIS.	Additional fish hatcheries were not included in the original construct of the Multiple Objective Alternatives, which focused on addressing eight objectives and measures for changing the operations, configurations, and maintenance of the 14 CRS projects. Hatcheries and the need for additional output was considered by the co-lead agencies and cooperating agencies during identification of mitigation actions for each alternative. Only MO3 was determined to need additional hatchery production for the short term impacts from breaching the four lower Snake River dams. Additional hatcheries were not identified as needed for mitigation under any alternative. See Chapter 5 for discussion of mitigation. However, the co-lead agencies will continue to fund existing conservation and safety net hatcheries under the Preferred Alternative. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. With respect to the Preferred Alternative, fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals.
2345	1	farmertuck@ymail.com	N/A	Transportation of farm produce. 10% of all US wheat exports are moved by barge down the Snake River. Barging is the safest, most efficient, climate friendly way to move wheat for export. One barge is the equivalent of 134 semi-trucks or 35 jumbo rail hoppers. Adding 135,000 more trucks annually would overwhelm our current highway system, making travel more dangerous. Current rail lines are at or near capacity and could not handle the added freight. We must also consider the fuel efficiency of barging. It would take another 5 million gallons of diesel annually if the same freight was moved via the truck to rail system. This would also add another 80 cents per bushel freight cost for farmers, already marketing a wheat crop at break-even or below cost of production.	The Navigation and Transportation Section (3.10) reflects the adverse effects of implementing alternative MO3, including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that could occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent). The co-lead agencies concur that barging is a more fuel efficient mode of transportation.
2345	2	farmertuck@ymail.com	N/A	With the billions of dollars spent to improve fish runs and several record or near record runs in recent years, well after the dams were in place, what is the real cause of decreased returns? Could it be warming oceans, predators, pollution and toxic waste in The Puget Sound? Federal studies show a 95% survival rate over the dams. If the dams are breached, we really have no way of knowing the effect on the fish, good or bad.	The co-lead agencies agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm
2356	1	vern2dkv@gmail.com	N/A	Sec. 2.4.6 Line 1895, p. 2-62 Under Structural Measures in Table 2-9, add a new structural measure to construct additional anadromous fish hatcheries upstream of Lower Granite Dam in Idaho to achieve recovery goals. This change is needed because the temporal scope of the EIS is 25 years. The past 50 years of investment for anadromous fish has not led to recovery of the fish. In 2019, salmon and steelhead returns were significantly below recovery goals for Snake River endangered salmon and steelhead. The amounts are dramatic regarding the recovery of these fish. Sockeye returns were 97% below recovery goals. Fall chinook was 76% below recovery goals. Spring/summer chinook returns were 70% below recovery goals. While steelhead were a dismal 66% below recovery goals. Another 25 years without achieving recovery goals will likely cause significant adverse impacts upon the Snake River anadromous fish and potential extinction unless recovery is addressed in the Columbia River System Operations EIS.	Additional fish hatcheries were not included in the original construct of the Multiple Objective Alternatives, which focused on addressing eight objectives and measures for changing the operations, configurations, and maintenance of the 14 CRS projects. Hatcheries and the need for additional output was considered by the co-lead agencies and cooperating agencies during identification of mitigation actions for each alternative. Only MO3 was determined to need additional hatchery production for the short term impacts from breaching the four lower Snake River dams. Additional hatcheries were not identified as needed for mitigation under any alternative. See Chapter 5 for discussion of mitigation. However, the co-lead agencies will continue to fund existing conservation and safety net hatcheries under the Preferred Alternative. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. With respect to the Preferred Alternative, fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals.
2357	1	vern2dkv@gmail.com	N/A	Sec. 3.5.2.3, Line 7219 The discussion provided addresses the highest return year for Bonneville Dam. To balance the discussion, lowest return year for Bonneville Dam should also be included. Snake River salmon and steelhead return should also be summarized by highest and lowest return years by specie. Furthermore including recovery levels for Snake River salmon and steelhead would depict an appropriate summary for those fish. Specifically in 2019, salmon and steelhead returns were significantly below recovery goals for Idahos endangered salmon and steelhead. Sockeye returns were 97% below recovery goals. Fall chinook was 76% below recovery goals. Spring/summer chinook returns were 70% below recovery goals. While steelhead were a dismal 66% below recovery goals. Increasing the number of salmon and steelhead migrating downstream will lead to increased salmon and steelhead returns. Columbia River System Operations should increase the number and capacity of the Idaho salmon and steelhead hatcheries. The Springfield salmon is designed to produce 1,000,000 sockeye salmon smolts. The sockeye recovery goal is 1,000 adults. The Idaho hatchery program for steelhead and spring, summer, and fall Chinook salmon should be expanded to produce the same ratio of smolts to adults for all these Snake River fish species to achieve salmon and steelhead recovery.	Recent declines in salmon returns post 2014 were acknowledged in Section 3.5. Additional fish hatcheries were not included in the original construct of the Multiple Objective Alternatives, which focused on addressing eight objectives and measures for changing the operations, configurations, and maintenance of the 14 CRS projects. Hatcheries and the need for additional output was considered by the co-lead agencies and cooperating agencies during identification of mitigation actions for each alternative. Only MO3 was determined to need additional hatchery production for the short term impacts from breaching the four lower Snake River dams. Additional hatcheries were not identified as needed for mitigation under any alternative. See Chapter 5 for discussion of mitigation. However, the co-lead agencies will continue to fund existing conservation and safety net hatcheries under the Preferred Alternative. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. With respect to the Preferred Alternative, fish analysis in Section 7.7.4 shows that it will provide substantial benefits to ESA-listed salmon and steelhead, which can help contribute to broader recovery goals.
2359	1	vern2dkv@gmail.com	N/A	Sec. 3.5.2.3 Line 7327, Metrics Since adults migrate upstream and juveniles outmigrate, smolt to adult ratio should be added to list of metrics to track Snake River salmon and steelhead survival and recovery. The number of smolts should be estimated to achieve adult recovery for each species of Snake River salmon and steelhead based upon achieving smolt to adult survivals associated with species recovery goals.	Smolt-to-Adult returns are highlighted throughout Section 3.5 and Chapter 7 as one of the primary metrics that the co-lead agencies are using to evaluate potential effects of each alternative. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on our fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is predicted to benefit salmon and steelhead. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
2360	1	vern2dkv@gmail.com	N/A	Sec. 3.5.2.3, Line 9906 The Comprehensive Passage Model, Version 2.0 documentation is available as a draft dated July 2, 2019. Independent reviews of the model were not provided or available. Modeling results from this model should be considered inconclusive until appropriate reviews are completed. The following statement on lines 9910 9911 should be deleted until the model is independently, peer reviewed. The COMPASS model attributes most of the recent variations in runs to ocean conditions and predicts small effects to change in spill. In the Independent Scientific Advisory Board for the Northwest Power and Conservation Council, Columbia River Basin Indian Tribes and National Marine Fisheries Service (ISAB) review of the Comparative Survival Study (CSS) Draft 2019 Annual Report, it was stated: The ISAB is concerned that the smolt-to-adult survivals (SARs) of Snake River wild spring/summer Chinook and steelhead continue to fall well short of the Councils 2%-6% SAR objectives. While the CSS is only the messenger of bad	All models used for decision-making in this EIS process are undergoing additional independent, external review. The outcome of this review will be included in the FEIS. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The co-lead agencies used current, high-quality and scientifically accurate information in the EIS analysis. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return (SAR) rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative (increasing from 2.0% to 2.7% for Chinook, a 35% relative increase). The NMFS COMPASS and Life Cycle models predict higher levels of risk

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				news, we reiterate our previously unanswered question that given the large amount of effort in the past to improve SARs through dam passage improvements, habitat improvements and other changes; to what extent might further improvements in hydrosystem management, predator control, and estuarine habitat lead to achieving SARs of 2%-6%? Since Columbia River System Operations alternatives address hydrosytem management, additional criteria for evaluation of these alternatives needs to be developed to address achieving SARS of 2%-6% for Snake River salmon and steelhead. ISAB further stated Smolt-to-adult survivals (SARS) continue to be very low. Do we have enough information to suggest changes to hydrosystem operations that could improve SARs? Line 9913 regarding predicts significant run recovery by increasing spill is not consist for every salmon and steelhead species discussed in draft EIS. That summary statement is misleading unless it is developed based upon recovery goals and SARs for each affected anadromous species. Alternatives for hydrosystem operations need to be modified and reevaluated to achieve SARS of 2%-6% for Snake River salmon and steelhead. Why does Columbia River System Operations continue considering alternatives that produce low SARS? These alternatives lead to adverse environmental impacts to Snake River salmon and steelhead and the likely extinction of these anadromous fish. Additional, revised and new Snake River Specific alternatives need to be developed and evaluated. These new alternatives must address methods to achieve SARS of 2%-6% for Snake River salmon and steelhead. Also these new alternatives need to achieve recovery levels for these Snake River fish.	associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. It should be noted that the average SAR targets referenced refers to the Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on our analysis of the Preferred Alternative, it will make a meaningful contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects.
2361	1	vern2dkv@gmail.com	N/A	Sec. 3.5.3.2 Table 3-61, Line 9976 Snake River Sockeye and Fall Chinook need to be addressed in the table. Estimated recovery levels for each species need to be added to the table. Provide the results in the table from each model-COMPASS, LCM, and CSS	Unfortunately, there are no existing models for juvenile survival or adult returns for Snake River sockeye or fall Chinook at this time. There are some in development that may be used in the future. We did not include estimated recovery numbers because these estimates are out of scope of this EIS effort and adult returns are the focus of regional parties as a metric for tracking change and effects to species.
2362	1	vern2dkv@gmail.com	N/A	Sec. 3.5.3.2, Table 3-61, Line 9976 MO3 and MO4 for Snake River Chinook and Steelhead modeling by CSS estimated smolt to adult return rates greater than 3%. LCM modeling estimated smolt to adult return rates at 1% or less. The two modeling results indicate approximately 400% difference. That range of uncertainty and comparability is not acceptable to demonstrate that Columbia River System Operations will not cause Snake River Chinook and Steelhead extinction. Additional modeling should be conducted for the Snake River salmon and steelhead such that MO3 and MO4 are integrated.	The co-lead agencies agree that, for some of the analyses, there are large differences in model outputs. However, these are the only regionally accepted models in use at this time. Those in development may be used in the future. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin.
2362	2	vern2dkv@gmail.com	N/A	Additional modeling should be conducted for the Snake River salmon and steelhead such that MO3 and MO4 are integrated. A suggested adaptive modeling is as follows. Snake River Alternative 1 Remove Lower Granite Dam, Relocate shipments to Barging Facilities downstream of Lower Granite Dam and including spilling at remaining dams from MO4 Snake River Alternative 2 Remove Lower Granite and Little Goose Dams, Relocate shipments to Barging Facilities downstream of Little Goose Dam and including spilling at remaining dams from MO4 Snake River Alternative 3 Remove Lower Granite, Little Goose Dams and Lower Monumental Dams; Relocate shipments to Barging Facilities downstream of Lower Monumental Dam and including spilling at remaining dam from MO4 The purpose of these additional alternatives is that many Idahoans want to see alternatives that work for everyone such that power, salmon and barging are evaluated together for the Snake River. This additional alternative analysis should be included in the Final EIS prior to the selected alternative for the Snake River	Both the benefits and adverse effects of MO3 and MO4 are included in the analysis. The impacts of both MO3 and MO4 are significant to several resources, but especially power generation and reliability. An alternative combining the two would exacerbate, not resolve, those power impacts, and thus, a combination of MO3 and MO4 is not a reasonable alternative under NEPA. MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g., increased incidence of blackouts). Without major additional of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire U.S. by 2023, per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching in MO3 would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. In developing the Preferred Alternatives, the agencies used the alternative analysis to optimize the combination of measures based on the measures' intent and performance, to minimize impacts and meet the Purpose and Need Statement and EIS objectives. See Chapter 7. In regards to moving barging facilities, these are not Federal facilities, and thus would be the responsibility of ports, private industry, regional or local entities. Relocation would not be an alternative that the Federal agencies would propose. However, breaching the earthen embankment and the changes to regional economies related to changes in navigation is included in the analysis of MO3. It is anticipated these entities would not move, but that industry would change to a different transportation option, such as trucking or rail.
2362	3	vern2dkv@gmail.com	N/A	Also, the hatcheries should be included in these three Snake River alternatives because rebuilding Snake River salmon and steelhead is a very important benefit to Idaho.	Additional fish hatcheries were not included in the original construct of the Multiple Objective Alternatives. Hatcheries and the need for additional output was considered by the co-lead agencies and cooperating agencies during discussions of mitigation actions for each alternative. Only MO3 was determined to need additional hatchery operations for the short term impacts from the measure breaching the four lower Snake River dams. See Chapter 5 for discussion of mitigation. However, the co-lead agencies will continue to fund existing conservation and safety net hatcheries with the Preferred Alternative.
2374	1	vern2dkv@gmail.com	N/A	The proposed action needs to be modified to achieve Snake River salmon and steelhead recovery goals.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is predicted to benefit salmon and steelhead. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
2374	2	vern2dkv@gmail.com	N/A	Sec. 3.5.4.1, Lines 20304 - 20308 MO3 is the only alternative that could lead to long-term increases in adult returns. Insufficient adult returns will not lead to achieving Snake River salmon and steelhead recovery goals. The proposed actions will not improve the likelihood of survival for Snake River salmon and steelhead. It is likely the proposed action will not lead to recovery of these salmon and steelhead, but leads to their extinction. The proposed action needs to be modified to achieve Snake River salmon and steelhead recovery goals.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is nevertheless predicted to benefit salmon and steelhead. It also meets all the other objectives of the study for resident fish, hydropower, water management, water supply and greenhouse gas emissions, while minimizing adverse impacts to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
2375	1	vern2dkv@gmail.com	N/A	The section should be modified to address recreational and commercial fishing throughout the system including the Salmon River basin that is not discussed in Section 3.11.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional eco nomic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The contribution of Columbia River origin fish to ocean fisheries is described in Section 3.15.2.1. Because there is considerable uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, effects associated with changes in commercial and recreational fisheries under the alternatives were described qualitatively. This analysis evaluates potential effects on fisheries by referencing the potential effects on relevant fish populations, as described in Section 3.5.
2375	2	vern2dkv@gmail.com	N/A	Sec. 3.11.1, Lines 92-93 The adverse effects noted are not limited to area tribes. The section should be modified to address recreational and commercial fishing throughout the system including the Salmon River basin that is not discussed in Section 3.11. Other recreational opportunities that should be added to this section include salmon spawning viewing in the Salmon River Basin.	The EIS recognizes the value of recreational and commercial fishing to the region. Section 3.15 describes the values associated with fisheries in the Northwest. Section 3.11 characterizes the sportfishing economy in the region. However, the uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, limits a quantitative analysis of the specific impacts of each alternative on these values. The effects are therefore discussed qualitatively. The social welfare effects on fisheries under MO3 are described as major and beneficial in the long-term, with increases in regional economic effects if commercial fish catch rates increase. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this

					region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
2390	1	vern2dkv@gmail.com	N/A	Sec. 3.11.2.1, Lines 307-318 This section on affected environment should include the Salmon River Basin, this omission needs corrected.	The specific geographic scope of the CRS proposed alternatives encompasses the 14 Federal projects on the Columbia River and its major tributaries (see Figure 1-1 in the Draft EIS). The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region.
2391	1	vern2dkv@gmail.com	N/A	Sec. 3.11.3.1, Lines 677 702 With the current return levels for Snake River anadromous salmon and steelhead being significantly below recovery numbers, fishing conditions are and will continue to be negatively affected from the presence of dams and system operations. Until Columbia River System Operations are modified such that Snake River anadromous salmon and steelhead returns are above recovery levels, these adverse effects should be included in the EIS as economic losses to recreation and commercial. The opportunity to eat Columbia River salmon and steelhead is routinely taken away of those individuals who enjoy these fish in their diet. In the EIS, steps should be identified to achieve anadromous salmon and steelhead recovery numbers, then after those steps are established, the steps become the baseline to evaluate the effects of the proposed alternatives. Evaluating the effects of the proposed alternatives without achieving recovery levels will lead to extinction of the Snake River anadromous salmon and steelhead.	Recovery goals set under ESA section 4(f) are separate and distinct from goals associated with the analysis of alternatives under NEPA. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative is predicted to benefit salmon and steelhead. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy. The effects of the alternatives on recreation and commercial fishing are provided in Section 3.11 and Chapter 7.7.13 and Section 3.15 and Chapter 7.7.17, respectively.
2392	1	vern2dkv@gmail.com	N/A	Sec. 5.2.1.1, Lines 226-240, page 5-6 Hatchery Actions have not achieved recovery levels of Snake River anadromous salmon and steelhead. Additional and improved supplementation hatchery actions pertaining to recovery of Snake River anadromous salmon and steelhead need to be defined and implemented to prevent extinction. These additional and improved hatchery actions need be identified and discussed in detail in the Columbia River System Operations Environmental Impact Statement including evaluation of smolt to adult (SARS) return ratio (at the hatchery location) as an acceptable measure of success. The Independent Scientific Advisory Board for the Northwest Power and Conservation Council, Columbia River Basin Indian Tribes and National Marine Fisheries Service recommends SARS of 2%-6% for Snake River salmon and steelhead. These new hatchery actions need to be included in the applicable sections in the remaining sections of the Mitigation Chapter.	Hatchery programs are included in the No Action Alternative and would be expected to continue under alternatives MO1, MO2, and MO4, and certain hatcheries would continue under MO3. No new hatchery programs are considered as mitigation under any alternatives, but MO3 does include increased hatchery production due to short-term impacts from breaching the four lower Snake River dams. Hatcheries and the need for additional output was considered by the co-lead agencies and cooperating agencies during identification of mitigation actions for each alternative. Only MO3 was determined to need additional hatchery operations for the short-term impacts. See Chapter 5 for discussion of mitigation. It should be noted that the 2-6% Smolt-to-Adult return (SAR) target referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the Preferred Alternative analysis, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery.
2393	1	vern2dkv@gmail.com	N/A	Sec. 7.7.4.1 Line 2746, Table 7-25 Recovery level (metric) for Snake River Spring/Summer Chinook should be added to this table. Also, estimated adult returns at the recovery level location (metric) should be added. It is very misleading (an insignificant change looks like a huge improvement when there is not improvement in recovery) to address % change for these fish until SARS are at recommended levels of 2%-6%. Sec. 7.7.4.1 Line 2831, Table 7-27 Recovery level (metric) for Snake River Steelhead should be added to this table. Also, estimated adult returns at the recovery level location (metric) should be added. Abundance estimates should be added as was included in Table 7-25. It is very misleading (an insignificant change looks like a huge improvement when there is not improvement in recovery) to address % change for these fish until SARS are at recommended levels of 2%-6%.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative (increasing from 2.0% to 2.7% for Chinook, a 35% relative increase). The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. It should be noted that the average SAR targets referenced refers to the Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on our analysis of the Preferred Alternative, it will make a meaningful contribution to recovery, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation, maintenance, and configuration of the 14 CRS projects.
2393	2	vern2dkv@gmail.com	N/A	Sec. 7.7.4.1 Line 2849, Provide a Summary table to include the abundance estimates should be included for Snake River Coho. It is very misleading (an insignificant change looks like a huge improvement when there is not improvement in recovery) to address % change for these fish until SARS are at recommended levels of 2%-6%.	Recovery goals set under ESA Section 4(f) are separate and distinct from goals associated with the analysis of alternatives under NEPA. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative (increasing from 2.0% to 2.7% for Chinook, a 35% relative increase). The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. It should be noted that the average SAR targets referenced refers to the Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on our analysis of the Preferred Alternative, it will make a meaningful contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation, maintenance, and configuration of the 14 CRS projects.
2393	3	vern2dkv@gmail.com	N/A	Sec. 7.7.4.1 Line 2880 Summary table including recovery level, estimated adult returns, and abundance estimates should be included for Snake River Sockeye Salmon. It is very misleading (an insignificant change looks like a huge improvement when there is not improvement in recovery) to address % change for these fish until SARS are at recommended levels of 2%-6%.	See response to Comment 2393-2.
2393	4	vern2dkv@gmail.com	N/A	Sect. 7.7.4.1 Line 2920 Summary table including recovery level, estimated adult returns, and abundance estimates should be included for Snake River Fall-Run Chinook Salmon. It is very misleading (an insignificant change looks like a huge improvement when there is not improvement in recovery) to address % change for these fish until SARS are at recommended levels of 2%-6%.	Recovery goals set under ESA section 4(f) are separate and distinct from goals associated with the analysis of alternatives under NEPA. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. It should also be noted that the 2%-6% recovery goals set by the NWPCC were initially based on spring Chinook salmon returns to the mouth of the Columbia River. Those same goals may not be applicable for all species with different life history strategies such as Snake River fall Chinook which have demonstrated population growth at SAR levels well below council targets for recovery.
2394	1	vern2dkv@gmail.com	N/A	Appendix E, Sec. 3.6.3.2, Line 4910, Table 3-22 With the SAR results being below 0.02 for LGR-BON and when formal consultation is completed, would Columbia River System Operations with NOAA Fisheries and/or US Fish and Wildlife Service develop Snake River specific alternatives that will achieve salmon and steelhead recovery levels?	No. We do not believe there would be a new alternative as the outcome of ongoing consultation. Consultation is based on the Proposed Action the co-lead agencies proposed to NMFS and USFWS. Recovery goals set under ESA section 4(f) are separate and distinct from goals associated with the analysis of alternatives under NEPA. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					region that have an influence and impact on ESA-listed species. The Preferred Alternative is predicted to benefit salmon and steelhead. It also meets the other objectives of the study for resident fish, hydropower, water management, and water supply, while minimizing adverse impacts to communities and the economy.
2397	1	appel1939@yahoo.com	N/A	I was raised on the Palouse and attended WSU in Ag Engineering. I worked for the USGS- Water Resources Division for 34 years as a Hydrologist. The first three years, 1961-63, I collected Water Data in eastern Washington; my field area was southeast Washington (the Snake River Basin in Washington State). This was before the Snake Dams and I collected river flow and water temperature data on the Snake 6 miles downstream from Lewiston. I moved back to the Colfax area in 1994 and I can attest to the facts that maximum river temperature data show that the river got hotter before the dams. This is primarily because the river was shallower and responded quickly to hot summer air temperatures. The dam pools that we have now act as a "heat sink" and tend to even the temperatures out therefore lowering the maximum extremes and raising the lower extremes.	These statements are in agreement with the historical data and modeling work that we have analyzed for this EIS. Historical water temperature measurements were collected from 1955 to 1958, which are reported in the EIS. This information helps to build historical context and provide an idea of what water temperatures would have looked like prior to the construction of the lower Snake River and Hells Canyon Complex dams. The lower Snake River dams include Lower Granite Dam (constructed in 1975), Little Goose Dam (constructed in 1970), Lower Monumental Dam (constructed in 1969) and Ice Harbor Dam (constructed in 1961), while the Hells Canyon reach dams include Brownlee (constructed in 1959), Oxbow Dam (constructed in 1961) and Hells Canyon Dam constructed in (1967). No Corps of Engineers Dams existed on the Snake River prior to 1961.
2397	2	appel1939@yahoo.com	N/A	The next item that concerns me is if the dams are removed there could be several generations (years) of fish kill due to the tremendous sediments loads in the river. Sediment has been collecting by settling on the bottom and shores since these dams have been constructed starting in early 1960s. It will move downstream as uncontrollably as flooding occurs, if dams are removed, suffocating salmon and steelhead, young and old.	Sediment loads to the Snake and Columbia rivers that could occur under the MO3 Breach Snake Embankments measure were analyzed using sediment transport models as described in Appendix C, Section 3.4. The sediment impounded behind the four lower Snake River dams is predominately fine grained and readily transported in suspension. Analysis results for the MO3 Breach Snake Embankments measure indicate that increased sediment concentrations could occur during the construction season with impacts to dissolved oxygen as described in Section 3.4.1 of Appendix C. Mitigation actions to address these potential impacts are described in Section 5.4.3, including transport of some listed fish. These short term major adverse impacts can only partially be mitigated. A specific discussion of mitigation for effects to anadromous fish from MO3 is included in Section 5.4.3.2. Sediment transport modeling suggests that impounded sediments within the historical river channel extents would scour back to the historical river bed elevations over the near-term (2-7 years) depending on the magnitude and duration of watershed hydrology. Impounded margin sediments remaining on higher elevation floodplain terraces would be expected to incrementally erode over a longer time (>10 years) as seasonal floods access those surfaces.
2413	1	sbruce54@yahoo.com	N/A	Excessive water spilling to help "flush" the fish down river is also questionable. It adds to erosion and may pose a nitrogen narcosis risk to all of the fish.	The co-lead agencies have evaluated the potential negative effects of increased spill and have worked to balance those against the predicted positive outcomes associated with high spill levels. This includes balancing the potential effects of erosion at the dams and increased total dissolved gas levels. The Preferred Alternative will be implemented using a robust monitoring plan to help determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored, as will other impacts to fish and the dams themselves. The co-lead agencies will, to the extent possible, account for effects from other sources such as harvest, ocean mortality, and straying.
2414	1	tvstanger@gmail.com	N/A	As a member of Bonneville Power Administration (BPA), we fulfill these goals. While LEC handles the safety aspect of our distribution services, BPA is a great partner in helping LEC achieve affordability and reliability. Although LEC desires to achieve environmental balance, we believe BPA and public power have provided many improvements that have produced positive tangible results in fish migration and the environment at a great expense to our member-owners. About one-third (1/3) of our wholesale power costs are spent on environmental improvements. Since wholesale power accounts for about 50% of LECs total expenses, roughly one-sixth (1/6) of our members electric bills are spent on environmental improvements via BPA. These costs are solely shouldered by the members of electric utilities, and residents of the Pacific Northwest. While BPA has a responsibility for fish migration, there are many other factors that contribute to fish survival and population increases. LEC believes there needs to be a holistic view of the entire fish life cycle not just the impacts of the dams. The solutions need to include hydro, hatcheries, harvesting, and habitat since they all are crucial to fish restoration efforts. The narrow view of what others believe are the responsibilities of public power in achieving positive results are prejudicially targeted and unfair to all members of LEC. LEC believes the responsibility for fish restorations should be borne by BPA, public power, and the residents of the Pacific Northwest. There needs to be an overall restoration effort by all concerned parties. This effort means all parties carry some accountability and are willing to give and take through open negotiations.	There are many effects to salmon and steelhead populations outside the operation and maintenance of the dams. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat (see Chapters 6 and 7 for additional information). Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-leads to meet congressionally authorized purposes while minimizing impacts to affected ESA species and their habitats. Finally, the financial responsibility for fish mitigation is not solely allocated to Bonneville's power ratepayers as the comment suggests. Fish mitigation costs are assigned to each authorized project purpose based on each purposes overall share of project costs, as determined by the cost allocation, by recovering those costs through power rates. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Congress also granted Bonneville discretion to fund the power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992, in some situations, including the Columbia River Fish Mitigation program. (Energy Policy Act of 1992, Pub. L. No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)). Bonneville generally does not, however, directly pay for the capital costs of fish mitigation structures; instead, it reimburses the U.S. Treasury for the power share of appropriations used to construct the structure. Additionally, as described in Section 3.19 of the EIS and Appendix Q, funding to operate the system comes through multiple mechanisms, including federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. For joint related costs, including funding for fish and wildlife mitigation actions, the Corps and Reclamation receive annual congressional appropriations to fund most, if not all, capital investments. Bonneville reimburses the U.S. Treasury for the power share of these appropriations. Once the investment is in place, Bonneville will typically direct fund the power share of the operations and maintenance costs associated with the facility. In addition to congressional appropriations for fish and wildlife and costs directly funded to Corps and Reclamation by Bonneville, the Bonneville Fish and Wildlife Program (which is separate and distinct from direct funding described above) funds hundreds of projects each year to mitigate the impacts of the federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the FCRPS. Bonneville uses its authority under 16 U.S.C. 839b(h)(10)(A), to make expenditures to implement its Fish and Wildlife Program. These expenditures provide system-wide funding for actions that also mitigate for the non-power purposes of the CRS, so Bonneville recoups the non-power share of those expenditures from the U.S. Treasury as credit, as required under 16 U.S.C. 839b(h)(10)(C). Bonneville's Fish and Wildlife Program expenditures incurred mitigating the CRS operations identified in the Final EIS and adopted in Bonneville's Mitigation Action Plan would continue to be allocated and borne as provided by existing laws governing the FCRPS and the long-standing accounting procedures used to implement them. Moreover, as described in Chapter 7 of the EIS, funding decisions for Bonneville's Fish and Wildlife Program are not being made as part of the CRSO EIS process. Future budget adjustments would be made in coordination with the regional entities that help Bonneville implement its Fish and Wildlife Program. The statement that roughly a quarter of costs from Bonneville's power rates are due to fish and wildlife spending is consistent with information provided in the EIS.
2414	2	tvstanger@gmail.com	N/A	While LEC believes positive results are achievable, the objectives that came from the EIS are not as beneficial to public power. Spill in any form is not ideal for electric utilities. Increased spill is also not ideal for fish survival since it can cause harmful or deadly amounts of gas in the water. Spill is wasteful and puts BPA in danger of not being able to provide reliability and affordability for the residents of the Pacific Northwest. Dam breaching holds no logic and would increase the reality of energy shortages in the Northwest very soon.	The EIS includes a Purpose and Need Statement in Chapter 1 and identified eight objectives in Chapter 2, which includes a purpose and objective to: "Provide an adequate, efficient, economical, and reliable power supply that supports the integrated Columbia River Power System." MO3, which includes the measure to breach the four lower Snake River dams was not identified as the Preferred Alternative. The Preferred Alternative meets the purpose and objective identified above. The Preferred Alternative which includes flexible spill will be implemented using a robust monitoring plan to help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored, as will the effects to generating resources around the basin. The EIS documents the reliability concerns and the costs associated with replacement power for spill or dam breaching for the various alternatives. See Section 3.7.3.5 in the Draft EIS.
2414	3	tvstanger@gmail.com	N/A	LEC is reliant on the affordable, clean, renewable energy we receive from BPA. However, reliability can only be achieved with the power produced by the Columbia River System. Reliable hydroelectricity is vital to incorporate intermittent generation sources like solar and wind into the grid. It would be counter-effective to spill more precious water or breach dams. We need to fully utilize the amazing resource we have available in the Pacific Northwest - clean, reliable, carbon-free energy produced by dams on the Columbia River System	The commenter's suggestion that hydropower is valuable for balancing intermittent generation sources such as wind and solar is consistent with the findings of the EIS. This is described further in Section 3.7.3.5, in the Draft EIS, Potential Replacement Resources and Associated Costs. The measure to breach the four lower Snake River dams that was evaluated in MO3, was not included in the Preferred Alternative identified in the Draft EIS. Juvenile Fish Passage Spill Operations are included in the Preferred Alternative identified in the Draft EIS as described in Section 7.6.3.10 of the Draft EIS. The effects of the Preferred Alternative on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the Preferred Alternative. However, because of the shape of the remaining hydropower generation in the Preferred Alternative, the loss of load probability was essentially the same as that of the No Action Alternative.
2415	1	orcharding@yahoo.com	N/A	Please wait until after the Coronavirus pandemic is over and hold the cancelled public meetings when people are aware and attentive to the Columbia River System Environmental Impact Statement and its objectives and measures.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
2416	1	justinacotter@aol.com	N/A	A major problem with the government's Preferred Alternative is its reliance on the flexible spill approach. Science shows that while increased levels of spill may ameliorate further species decline in the short term, it is not, by itself, a long-term survival strategy, let alone a recovery strategy. Indeed the parties to the current, short-term Flexible Spill Agreement made this explicit, and respected scientists have confirmed that the flexible spill included in the Preferred Alternative will NOT deliver salmon the survival benefits through the hydrosystem they need. Furthermore, the changing climate will erode any benefits of flexible spill as a long-term approach, underscoring the urgency for meaningful action. Rather shockingly, the draft plan includes little to address these intensifying impacts. Snake and Columbia river salmon and steelhead and the irreplaceable benefits they bring to communities and orcas and ecosystems face extinction today. The approach recommended by this Draft EIS as a long-term strategy for Columbia Basin fish will result in nearly certain extinction for the four remaining endangered Snake River stocks: sockeye, spring/summer chinook, fall chinook and steelhead.	As required by NEPAs implementing regulations, the co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. There are many factors that affect salmon and steelhead populations including changes to ocean conditions, predation, harvest, etc. The analysis in this study, particularly relating to the fish passage spill operation, focus on the migratory impacts to salmon and steelhead from the operations of the Columbia River System projects. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Based on our analysis in the fish resources section of Chapter 7.5, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call however is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
2418	1	kennedy@mymail.mines.edu	N/A	I have a question: within the information for each dam (for example, the John Day Dam: https://www.nwd.usace.army.mil/CRSO/Project-Locations/John-Day/#top), listed is the hydraulic capacity in cfs. Is this number (322 thousand for the John Day Dam) the total cubic feet per second going through the dam, or per turbine? If this were the total, is it fair to say that each turbine (in the John Day Dam) can take in 322/16 cfs, as there are 16 turbines? Thanks, and I look forward to your response.	The "quick facts" listed for the dams at the CRSO website (for example, https://www.nwd.usace.army.mil/CRSO/Project-Locations/John-Day/#top for John Day Dam) include Powerhouse Hydraulic Capacity. The Powerhouse Hydraulic Capacity is the total amount of flow that could pass through the powerhouse, meaning for all the generating units combined. It is not for a single generating unit. So at John Day Dam, which has a Powerhouse Hydraulic Capacity of 322,000 cfs, the hydraulic capacity of each individual unit is 1/16 of the Powerhouse Hydraulic Capacity. This amounts to 20,125 cfs per unit.
2419	1	allensandra524@turbonet.com	N/A	The shutting down of various railroad spurs on the Palouse caused a very noticeable increase in heavy truck traffic on the roads and highways of eastern Washington with corresponding increase in traffic safety concerns for all of us. The breaching of the dams will have an even greater impact on traffic safety, as well as the increased cost of grain and other cargo transport to and from the area.	The Navigation and Transportation Section 3.10 reflects the adverse effects of implementing alternative MO3 including increases to traffic, potential safety, and cost of grain transport. The EIS analysis finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent).
2421	1	Charles Tracy	Pacific Fishery Management Council	The Pacific Council would like to provide comments on the draft environmental impact statement for the Columbia River System Operations (DEIS); however, in response to the current COVID- 19 pandemic, the Pacific Council was forced to change its April 5-10 in-person meeting to a webinar format and cut back its agenda to only essential rulemaking items. Unfortunately, the agenda item to approve comments on the DEIS was a casualty of the agenda prioritization. While another process to obtain consensus comments from the Pacific Council exists, this process is less robust than our usual Pacific Council meeting discussions involving Council members, advisors, and stakeholders. The next opportunity to engage in our usual process will be at our June 13-18 meeting; therefore, we are requesting an extension of the comment deadline on the DEIS until at least June 19, 2020. We recognize this is a substantial delay, but the actions considered in the DEIS are extremely important to the Pacific Council, its stakeholders, and the fishery	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The Corps notified the Council on April 6 and the public on April 9, that they should plan to submit comments by the close of the comment period.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				resources managed by the Pacific Council. If an extension until then is not possible, we would appreciate your consideration of any extension of the deadline beyond April 13 to allow us to complete our alternative commenting process in a more considered manner. Thank you for considering our request. Please contact me or Ms. Jennifer Gilden, our staff lead, if you have any questions. We look forward to your response and the opportunity to provide meaningful comments on the DEIS. Sincerely, Charles A. Tracy Executive Director JDG:ael Cc: Mr. Chris Oliver Council Members Habitat Committee Salmon Advisory Sub	
2423	1	ahoey@owgl.org	N/A	The Columbia Snake River System is the nations single largest wheat export gateway. Barging plays a key role in this transportation system and moved over 4 million tons of wheat to Lower Columbia River ports last year. Each year, nearly 10% of all U.S. wheat exports move by barge just on the Snake River. A significant concern to any dam removal on this system is the impact to truck and train activity that would be necessary to take the place of barging. It would be simultaneously devastating to our economies and wheat growers while also significantly diminishing air quality due to increase emissions. I applaud the approach taken in this study and support the recommendations put forth for the preferred alternative. Continued improvements to fish passage at the four Snake River dams enable fish to pass the dams with remarkable success. Dams with navigation locks providing barge transportation can and do, in fact, coexist with fish. The ability to barge wheat is a pillar of our industry. Loss of these four facilities would cause irreparable damage to the Pacific Northwest economy, including Oregons wheat growers, not limiting to, Transportation and storage expense would likely increase 50% to 100% for grain suppliers and shippers. These costs could increase by up to $0.80 per bushel if barging on the Snake River is removed as a transportation option. Diesel fuel consumption would increase by nearly 5 million gallons per year as barges are replaced by much less efficient truck-to-rail shipments. Highway, rail and grain elevator networks would need over $1.6 billion in capital investment. The loss of hydropower generation would reduce the baseload power available to balance the power provided by variable generation sources like wind and solar. Carbon emissions from transportation and replacement power generation would greatly increase, something the State of Oregon is supposedly trying to reduce with countless other policy initiatives.	Section 3.10 of the Draft EIS provides an evaluation of the Columbia Snake River Navigation System, assessing its relative efficiency, low costs for shippers, safety considerations, and low air emissions relative to other transportation modes. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required. Under low rail rate increase scenarios, additional shortline rail capacity could be required at a cost of between $25 to $50 million. Under a scenario where rail rates increase by 50 percent, more shipping demand would be transferred to trucks, reducing the demands on rail infrastructure, but increasing demands on roads. Under this scenario, up to $10 million in additional road wear and tear costs may occur. Environmental and human health impacts associated with increased emissions to shipping goods by rail and/or truck are evaluated and described in the Air Quality Section (3.8), and increased health and safety concerns due to increased truck traffic on roadways and potential for increased accidents are described in the Navigation and Transportation Section for other social effects (Section 3.10.3.5). Regarding the loss of hydropower, the commenter's observation about the balancing ability of the four lower Snake River dams is consistent with the findings of the EIS. The commenter's observation about emissions increasing from transportation and power generation is also consistent with the findings of the EIS.
2424	1	moffpirx@aol.com	N/A	With reference to Appendix H, Section 2.4 "Comparison fo NWEC study with the MO3 All-Gas Alternative" page H-2-16, line 928 to 940. The Groups in support of MO3 and /or MO4 are utilizing the findings of the NW Energy Coalition "Lower Snake River Dams Power Replacement Study - March 2018" by Energy Strategies. As lines 928 to 940 in the CRSO EIS state, the NW Energy Coalition study utilizes out of date information, and is opaque with respect to a number of assumptions used in their models. In addition... 1) The NW Energy Coalition study has not been updated, and does not take into account the NWPCC 7th Power Plan Mid-Term Update, which significantly reduces the amount of Energy Efficiency and Demand Response which is anticipated. 2) The NW Energy Coalition study produces LOLP numbers for all of the replacement scenarios that are drastically less than the concensus of estimates for LOLP from BPA, NWPCC, PNUC, E3, and others. 3) It is not clear from the NW Energy Coalition study that ELCC (Effective Load Carrying Capacity) for wind and solar was correctly used in their models. 4) The NW Energy Coalition study only lightly considers the magnitude and timing of new Transmission lines that will need to be built to accommodate the increased renewable resources. 5) NWEnergy Coalition does not explicitly state that it does not anticipate removing the dams until approximately 2026. There are other areas of concern. For the above, and other issues, the NW Energy Coalition Study should not be considered as an authoritative document to justify MO3 or MO4.	The commenter's note the four lower Snake River dams' power replacement portfolio described in the Northwest Energy Coalition study cannot be compared to MO3 within the EIS is correct. The EIS section cited by the commenter (Appendix H, Power and Transmission, Section 2.4 in the draft EIS) describes the differences between these studies.
2426	1	murphyjeanie@hotmail.com	N/A	First off, the fact that Northwest ratepayers will be devastated by the costs of replacing the power lost if the four lower Snake River dams are removed is incorrect. The four lower Snake River dams are relatively unreliable sources of power compared to some other dams in the federal Columbia River system. They are run of the river dams with very little storage capacity and are thus almost totally dependent on the amount of snowpack and rate of runoff. While they have a collective generating capacity of 3,033 megawatts, their average yearly output is around a third of that 1,075 average megawatts (aMWs). Together, these four dams produce only 790 aMWs of firm power (i.e., the amount of electricity utilities can count on in a drought year). And even that is misleading, since most of that potential exists in spring when the region has a power surplus. When the energy is most needed in winter and late summer, these dams are good for only 425-525 MWs. If Seattle had to rely on the lower Snake dams for its power, it would have electricity shortages much of the year. Because of the unreliability of these four dams, the Northwest Power and Conservation Councils 6th Energy Plan shows that the region would only need to replace about 245 MWs of additional power to address the current output of these dams. The impact on customers rates would be somewhere between 2-4% percent if spread throughout the region, refuting claims that dam removal would devastate ratepayers. Renewable energy and conservation can replace the lost generation or cover future load growth if the four lower Snake River dams are removed. The 2009 Bright Future report from the NW Energy Coalition illustrates that there is enough affordable energy efficiency and renewable energy resources in the Northwest to satisfy load growth, phase out all of the regions carbon-emitting coal plants, and replace the modest amount of power coming from the four lower Snake River dams. Furthermore, the Northwest Power and Conservation Councils 6th Power Plan, released in 2010 underscores many of the findings in Bright Future. The Councils plan shows that the region can meet its growing energy needs almost entirely with energy efficiency and new renewables and with no net increase in greenhouse gas emissions. In addition to being much cheaper and cleaner than gas, reducing loads through conservation frees up valuable transmission capacity needed to integrate more renewables in the Columbia Gorge, and reduces the need for the peaking ability of the dams. Both the Bright Future and the 6th Plan show that we have a sensible and affordable path toward a Northwest energy future where regional carbon emissions are reduced enough to meet the regional climate targets and the lower Snake River is restored for the benefit of salmon, jobs, and communities. The lower Snake River dams are NOT necessary to ensure that wind power can be integrated into the power grid. Removal of the four lower Snake River dams will not significantly increase the cost to integrate or back up wind resources into the grid. Hydropower facilities can firm or back up wind generation by leaving water in the reservoir when the wind is blowing and generating power, and then releasing the water to generate power when the wind is not blowing. But the problem now in the region is that we actually have an excess of hydro capacity at certain times of year that creates a limitation on how much wind we can allow onto the energy grid. Removing the four lower Snake River dams would help to eliminate that problem and thus allow more wind energy to be brought onto the system.	The Draft EIS describes the operational characteristics of the four lower Snake River dams in Section 3.7.3.5, Lower Snake River Full Replacement (Used in Rate Sensitivity Analysis). As described in that section, although the dams are run-of-river, there is upstream storage that is used to increase their firm capacity, and they provide up to 2000 MW of sustained peaking capacity at certain times of the year. Yes, the commenter is correct that they have less firm power in the winter than their annual average, but some of this winter generation can be shaped to meet demand during the morning and evening peaks when it is most needed. They also have unparalleled ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to approximately 2,300 MW of capability in certain months of the year (see Table 3-160 in the draft EIS). The ramping capability is valuable for system balancing, which is used to serve load (consumed energy by houses, business, industry) and to balance out the variability that renewable generation causes to the system, such as when the wind does not blow or the sun is blocked by clouds. The comment also seems to suggest that the four lower Snake River dams are operated independently of the remaining parts of the Federal Columbia River Power System (FCRPS). As the Draft EIS describes, the FCRPS is operated as an integrated system. Consistent with that operation, Bonneville sells power from the FCRPS as a unified system, not from specific projects. In this regard, the power generated from the four lower Snake River dams are used to meet Bonneville's collective power obligation, most of which is sold to meet the loads of publicly owned utilities, such as municipalities, rural utilities, and public utility districts (see Section 3.7.2.5, Bonneville Power and Transmission Customers in the draft EIS). The EIS used the most recent data from the Northwest Power and Conservation Council's 7th Power plan and Mid-term Updates to analyze regional reliability, the need for replacement resources, and the potential for additional energy efficiency. The Councils 7th Power Plan was issued in February 2016 and the Mid-Term Update was issued in February 2019. The information relied on by the commenter is from the Councils 6th Power Plan, which as the commenter notes, is from 2010. In addition, regarding the specific replacement resource considerations from the Bright Future report and the Council's 6th Power Plan, these studies are 9 or 10 years old and do not reflect the newer information contained in the 7th Power Plan. All cost-effective efficiency was included in the analysis. There is a zero-carbon resource portfolio that includes renewables as well as demand response. Additional energy efficiency in the zero-carbon portfolio was not deemed cost-effective compared to the renewable resources. The EIS identifies an average retail rate increase of 2-4% across all retail ratepayers in the region as a result of MO3. This range includes impacts to utilities that do not directly purchase power from Bonneville (such as private utilities) as well as utilities that do (such as public utilities and municipalities). The retail rate impacts of MO3 on customers that purchase power primarily from Bonneville would be higher than the 2-4 percent increase cited by the commenter. For example, as explained in Section 3.7.3.5, Table 3-174 in the draft EIS, if a zero-carbon resource portfolio were chosen to replace the lost capability of the four lower Snake River dams, 20 percent of regional households would experience a greater than five percent rate increase. Table 3-174 in the draft EIS also describes how 58 percent of regional households would see a retail rate increase of between 3 and 5 percent. The EIS describes the replacement resources that would be needed to maintain regional reliability at the No Action Alternative (No Action Alternative) levels if the four lower Snake River dams are breached. Two portfolios are addressed in the EIS: a least-cost conventional portfolio (natural gas) and a zero carbon portfolio (solar, wind, storage technologies). See Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS. To maintain regional reliability at the No Action Alternative levels with zero carbon resources portfolio, 2,550 MW of solar and 600 MW of demand response would be needed. As described in the EIS, this is approximately 1,550 MW above the regions 1000 MW of installed solar. (The final EIS has slightly smaller quantities as well as batteries, See final EIS Section 3.7.3.5.) In addition, as discussed in Section 3.7.3.5 in the draft EIS, Lower Snake River Full Replacement, replacing the lost capability of the four lower Snake River dams would require substantially more additional zero-carbon resources than presented in the reliability analysis, including a total of 3,306 MW of solar, 1,144 MW of wind, and over 2,500 MW of batteries or other storage technology. See Table 3-162 in the draft EIS. The EIS found that even with adding zero-carbon resources such as solar and demand response to replace lost hydropower from dam breaching, greenhouse gas emissions still increased in the region because existing gas-fired power plants in the region would increase generation. See Section 3.8.3.5, Summary of Effects in the draft EIS. The EIS describes the importance of maintaining balancing reserves to meet system uncertainty and to integrate renewable resources, such as wind and solar. See Section 3.7.2.2, Meeting System Uncertainty With Generation Balancing Reserves, Dispatchable Resources, And Ramping Capability in the draft EIS. The four lower Snake River dams are connected to Automatic Generating Control (AGC), making them among the few projects that are capable of providing balancing reserves. See Section 3.7.3.5, Value of Lower Snake River Dam Ramping Capability in the draft EIS. The four lower Snake River dams currently carry approximately 20 percent of upward flexibility and 8 percent of the downward flexibility held by the FCRPS for balancing reserves. See Section 3.7.3.5, Rates Sensitivity Analysis in the draft EIS. As discussed in the EIS, breaching the four lower Snake River dams would place this balancing reserve obligation on the remaining projects tied to AGC, reducing their available generating capability. In addition, the need for balancing reserves would increase in order to reliably integrate the zero-carbon resources needed to replace the lost capability of the four lower Snake River dams. The cost of these integration services is presented in Section 3.7.3.5, Bonneville Finances, and Table 3-166 in the draft EIS.
2426	2	murphyjeanie@hotmail.com	N/A	Removing the lower Snake River dams will NOT hurt farmers and irrigators. Removal of the lower Snake River dams need not have a detrimental impact on farmers in eastern Washington. Prior to the completion of those dams in 1975, grain and other products in the region were transported to market chiefly by rail and truck. Today, a significant portion of these products moves via barge from Lewiston, Idaho, or grain-loading facilities elsewhere on the lower Snake River. Recent studies have found that the 140-mile navigation channel created by the lower Snake River dams could be affordably and effectively replaced by upgrading the Northwests railroad lines. Upgrading railroads in southeastern Washington and Idaho to accommodate most of the grain currently moving down the lower Snake River (some would still be barged from Columbia River ports near Pasco, Washington) would not be cheap, but it can done cost-effectively. Regarding irrigators in the Columbia-Snake basin, removal of the four lower Snake River dams could actually take pressure off upriver irrigators in Idaho, who under an aggressive non-dam-removal plan would need to let more water remain in the river to mitigate for the effects of the dams. And the relatively small amount of irrigated farmland along the lower Snake River (Ice Harbor Dam is the only one that provides irrigation for farms) could be replaced by extending intake pipes to a free-flowing river. Similarly, dryland wheat farmers could retain an affordable, reliable transportation system if some of the taxpayer savings from dam removal are invested in upgrading railroads, highways, and Columbia River barge facilities.	This EIS discusses engineering solutions (pipeline extensions for example) in Section 3.12.3 Environmental Consequences, specifically under Region C under the MO3 alternative (see page 3-1267, line 3244 in the Draft EIS) and in Appendix N. The report from which this EIS draws, as discussed, concluded that modifying the existing pump system was cost prohibitive. In Region C under the MO3 alternative, this analysis assumes that pumps are unable to deliver water to an estimated 48,000 acres. The EIS evaluates the increases in transportation rates that would likely result from removal of lower Snake River navigation capability from dam breach. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled, depending on their specific location and other conditions. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. The EIS acknowledges previous analyses conducted in the 2002 lower Snake River study. However, the EIS relies on the best, currently available information to evaluate the tradeoffs associated with dam breach under MO3.
2426	3	murphyjeanie@hotmail.com	N/A	Salmon are NOT doing better than ever and returns are NOT approaching historic levels. Contrary to repeated statements from federal agencies, most wild Snake River salmon and steelhead returns remain at about the same levels as when they were first listed under the Endangered Species Act (ESA) in the early 1990s. But around 80% of these returns are hatchery fish, not wild ones. And while those numbers were predicted to be near or slightly below the 10-year average, they are less than half of the numbers we saw as recently as 2001 and 2002. More importantly, the wild returns are still nowhere near NOAA recovery targets, which must be met for eight consecutive years, or the Councils replacement or recovery targets. Many claim that removing the four lower Snake dams will only help four of the thirteen ESA-listed species in the Columbia-Snake Basin. In truth, while the four Snake River salmon and steelhead populations will benefit the most from the removal of the four lower Snake River dams, this action will also help improve water quality and flow in the lower Columbia River, thus benefiting all 13 listed stocks that migrate through the Columbia. Furthermore, a salmon recovery plan including dam removal could free up funding for salmon recovery efforts elsewhere in the Columbia Basin. The science is clear that lower Snake River dam removal is the best hope to restore salmon runs in the Basin. Among other sources, the Plan for Analyzing and Testing Hypotheses	As required by NEPAs implementing regulations, the co-lead agencies used high-quality information in the analysis of the CRSO EIS. Therefore, the agencies did not rely on information contained in the Plan for Analyzing and Testing Hypotheses (PATH) Weight of Evidence Report (ESSA Technologies 1998), which is over twenty-years-old and does not reflect current CRS operations. In addition, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				(PATH, a group of federal, state, tribal, and independent scientists convened by the Clinton Administration in the mid-1990s to examine the causes of Columbia and Snake River salmon declines and the best courses of action for reversing those declines) report from 1998 concluded that removing the lower Snake River dams had an 80 and 100% probability, respectively, of recovering Snake River spring/summer chinook and fall chinook. In addition, NOAAs 2000 Biological Opinion concluded that dam removal was the most biologically certain way to recover Snake River salmon: [B]reaching the four lower Snake River dams would provide more certainty of long-term survival and recovery than would other measures. According to the American Fisheries Society, [i] n contrast to the uncertainty of success from the removal of hydro projects in other portions of the basin, the benefits to Snake River stock survival and recovery would be assured with the removal of the lower four dams on that system... The real problem for Columbia and Snake River salmon is NOT climate change and NOT ever-changing ocean conditions. By far the biggest killer of endangered wild salmon and steelhead are the dams on the lower Snake and mainstem Columbia. In fact, the current federal salmon plan permits the federal dams to kill more than 90% of some of these salmon. Yet NOAA and BPA have consistently downplayed those impacts and instead have attributed both good and bad salmon returns to ocean conditions. The best science shows us that the most effective way to ensure strong salmon returns in variable ocean cycles is to fix their freshwater habitat and that begins with the removal of the four lower Snake River dams. While dam removal is not a silver bullet, with strong actions including dam removal, salmon populations will be better able to weather poor ocean cycles in good health and truly thrive when ocean conditions are good. Thanks to their extensive high-elevation habitat in the mountain rivers and streams of Idaho, NE Oregon, and SE Washington, Snake River salmon and steelhead are well-positioned to survive and thrive in spite of climate change but only if the four warm, predator-filled reservoirs on the lower Snake River are replaced with a cooler, swifter, free-flowing river.	Different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase - smolt-to-adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River spring/summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other.
2426	4	murphyjeanie@hotmail.com	N/A	Removing the lower Snake River dams will NOT cause economic devastation and thousands of lost jobs.Federal taxpayers and Northwest ratepayers have already spent upwards of $10 billion on salmon recovery efforts in the Columbia-Snake River Basin for fairly little in return. The federal government has indicated that the current plan will cost an additional $700 million to $1 billion per year to continue the same general activities that we have been doing for the last decade, but which are not achieving sustainable salmon populations. At the same time, the fishing industry has lost more than 25,000 jobs because of salmon declines in the Columbia- Snake Basin. We cannot afford to continue down this path and lose any more jobs. A RAND Corp. analysis, as well as one by a coalition of taxpayer, energy, fishing, and conservation groups, found that removing the Snake River dams may be cheaper in the long run than continuing to spend resources on the failed strategies of the past. In fact, the latter study found that as much as $1.6 to $4.6 billion could be saved with the removal of the four lower Snake River dams. And RANDs analysis found that, if done well, dam removal could actually produce as many as 15,000 new, long-term jobs. If expanded fishing business opportunities are included in the economic picture, lower Snake River dam removal could bring billions of dollars in increased economic benefits to the Northwest from expanded fishing (both sport and commercial), new river-based recreational opportunities, and non-recreational revenue. I am asking you to breach the Lower Snake River Dams to save our salmon and save the Resident pods of Orca whales that depend on them.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Section 3.5. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. Table 7-1 in Chapter 7 (Preferred Alternative) provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives. The EIS acknowledges previous analyses conducted in the 2002 lower Snake River study. However, this EIS relies on the best, currently available information to evaluate the tradeoffs associated with dam breach under MO3. The EIS acknowledges previous analyses of breaching the four lower Snake River dams, such as the 2002 RAND analysis referenced in this comment. However, the EIS relies on current information to evaluate the tradeoffs associated with dam breach under MO3. This includes applying current models and data rather than relying on findings from studies conducted nearly 20 years ago. Section 3.7 of the EIS describes potential uses of zero-carbon resources (alternative resources) to meet the energy demands in the Pacific Northwest if hydropower generation is reduced. The social welfare effects on fisheries under MO3 are described as major and beneficial in the long-term, with increases in regional economic effects if commercial fish catch rates increase (Section 3.15). For the effects on recreational fishing under MO3 (Section 3.11.3.5), the evaluation considers fishing visitation in other similar river reaches. There is some uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. However, the EIS does describes that the visitation in the long-term, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting recreation and tourism businesses. The costs of dam breaching are described in Section 3.19.2 and in Appendix Q. MO3 would result in decreased costs or funding requirements for the lower Snake River projects as compared to the No Action Alternative, including capital costs, operations and maintenance, non-routine navigation, non-routine extraordinary costs, and F&W mitigation costs. However, dam breaching and infrastructure drawdown would result in construction costs and costs for additional mitigation measures to address the adverse effects of MO3.
2436	1	N/A	N/A	I am requesting an extension to the comment period. Given the fact that there will be no public meetings and there is so much concern and attention on the COVID-19 situation, the public will need more time to read and comment on this important issue. Thank you.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
2437	1	julianne.m.dirks@gmail.com	N/A	With dam removal, I believe similar protocols from the Elwha will be considered to ease the sediment transportation when they are being breached. This step is essential to control water quality. Also with dam removal, in order to stabilize the river and to ensure flooding protection from cities, wold log jams be considered to create habitat for fish and guide where the river will flow?	The sequencing and rate of breaching of the four dams was set to optimize the construction season within the in-water work period and minimize the duration of impacts to fish passage. If this alternative were selected in the ROD, additional analysis and modeling would be anticipated that would look to balance the duration and magnitude of impacts with the rate and method of removal. If MO3 were selected for implementation, detailed engineering and design and site specific NEPA evaluations would take place prior to implementation. Additional opportunities for environmental enhancements, such as log jams, could be considered at that time. This would be in accordance with the Corps' Environmental Operating Procedures.
2445	1	stanbos11@gmail.com	N/A	Note the 1951 flooding that backed water up the Willamette river flooding Oregon City. How can we expect this scheme for fish run rebuilding to be successful when the same fish is commercially harvested all along the Columbia river? There is no solid evidence that the fish run would be enhanced by removal of the dams and improvements in the number of fish would soon be harvested before the fish has chance to return.	Any potential changes to harvest rates as a result of implementation of the measures in range of alternatives are discussed in Chapter 3.15 and 7.7.17, Fisheries and Passive Use.
2458	1	laura@ucut-nsn.org	N/A	Several of the UCUT Tribes have engaged as cooperating agencies in the analysis necessary for the Draft EIS, and we are writing to urgently request that you extend the public review and comment deadline for the CRSO Draft Environmental Impact Statement that was released on February 28, 2020 with a 45-day comment period. The 45-day deadline has become impossible for our member Tribes to meet given the outbreak of COVID-19. Each of the UCUT Tribes' governments have restrictions on staff and are under partial shutdowns to do their part to help flatten the curve and control the spread of the virus. Just as the federal government has limited work within your agencies and shifted focus to this National Emergency, the UCUT Tribes too are managing this crisis while needing to keep their government's operational to meet their citizens' basic needs. Ultimately, the constraints from this unexpected National Emergency must be considered and the comment period must be extended. A 120-day period was allowed for the preliminary scoping step for the CRSO EIS. Also, a comment period of 120 days or more would be consistent with the sworn statements from your agencies to the Court in NWF v. NMFS, No. 01-640-SI (D. Or.). As you are well aware, each of our member Tribes has trust and/or treaty resources that will be impacted by the federal decisions made within the preferred alternative and eventual Record of Decision . It is well within your federal trust responsibility owed to the Tribes to extend the arbitrary deadline. With limited staff during this pandemic our member Tribes are simply unable to meaningfully review and comment by the 45-day deadline. Therefore, we request that you extend the comment period to 120-days or more to allow for meaningful involvement for our member Tribes during this time of crisis. If you have any questions following review of this request, please contact DR Michel, UCUT Executive Director, at (509) 209-2412 (office) or (509) 954-7631 (cell) and/or by email at dr@ucut -nsn.org. Sincerely, Donald R Michel, Executive Director	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
2460	1	jennifer@tidewater.com	N/A	Tidewater, the other river transportation service providers, and they Columbia-Snake River system of dams and locks, are essential to continuing the cost-effective and fuel-efficient transportation of goods - connection the farthest inland port in the country to markets in the Northwest and abroad. One barge with tow can ship the equivalent goods of 1.4 100-unit freight trains, or 538 semi- trucks. These trains and trucks would congest our communities, increase greenhouse gas emissions, and decrease air quality if we lose the system of dams and locks that enable barge shipments. Regional deep-draft ports, such as the ports of Portland, Vancouver, Kalama and Longview, rely on barging to help move products from inland communities to export facilities. Grains and other commodities are barged via the Columbia-Snake River System to these deep-water ports and shipped to trade partners all over the world, supporting more than 40,000 local jobs, including mine. Barging is nearly 40% more fuel-efficient than freight trains, and 270% more fuel-efficient than semi-trucks. In 2018, it would have taken 38,966 rail cars or 149,870 semi-trucks to move the 3.9 million tons of cargo shipped on the Snake River alone.	The co-lead agencies concur that barging is a cost effective and fuel efficient method to transport commodities. Additionally, an analysis of changes to congestion and air quality are also included in the EIS and represent an adverse impact to transportation and communities with implementation of alternative MO3. The Navigation and Transportation Section 3.10 reflects the adverse effects of implementing MO3 including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent).
2462	1	kristinab@inlandpower.com	N/A	Inland Power, along with all other Washington utilities have been charged with becoming carbon-neutral by 2030 and 100 percent carbon-free by 2045. The lower Snake River dams are essential to reaching the Northwests clean energy goals.	The EIS recognizes the relevance of the Washington Clean Energy Transformation Act, among other regional emissions reductions targets, in Section 3.7 Power and Transmission analysis and Section 3.8 Air Quality and Greenhouse Gases emissions analysis. The analyses evaluates the extent to which the CRSO EIS MOs influence the ability of the region to meet these objectives, finding that MO3, which includes breaching the four lower Snake River dams, would make these goals more difficult to meet.
2462	2	kristinab@inlandpower.com	N/A	These dams also help us safely add intermittent renewables, like wind and solar power, to the grid. The hydroelectric turbines at the dams can very quickly fill in the gaps when the sun doesnt shine and the wind doesnt blow, keeping the grid balanced.	The statements that the four lower Snake River dams enhance the ability of the power system to integrate new renewables and to ramp up to meet load are consistent with the findings of the EIS. See draft EIS, Section 3.7.3.1, Integration Services at page 3-832 and Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907.
2462	3	kristinab@inlandpower.com	N/A	I urge you to strongly consider the numerous negative results that would occur should these vital dams be removed. Our state would suffer greatly from an economic, energy, job, agricultural, trade and environmental standpoint.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.

2487	4	brians@inlandpower.com	N/A	These dams also help us safely add intermittent renewables, like wind and solar power, to the grid. The hydroelectric turbines at the dams can very quickly fill in the gaps for wind and sunshine, keeping the grid balanced.	The statements that the four lower Snake River dams enhance the ability of the power system to integrate new renewables and to ramp up to meet load are consistent with the findings of the EIS. See draft EIS, Section 3.7.3.1, Integration Services, at page 3-832 and Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907.
2487	5	brians@inlandpower.com	N/A	I urge you to strongly consider the numerous negative results that would occur should these vital dams be removed. Our state would suffer greatly from an economic, energy, job, agricultural, trade and environmental standpoint.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most of the other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
2488	1	galer@inlandpower.com	N/A	As a dry land and irrigated farmer in Lincoln County, the four lower Snake River dams are vital for the continued survival of my familys business. These dams provide the only source of irrigation for tens of thousands of acres in eastern Washington.	Your statements concerning land irrigated from Lower Snake River dam pools is consistent with the description in the EIS. In Region C under the MO3 alternative this analysis assumes that pumps are unable to deliver water to estimated at 48,000 acres. Please see Section 3.12 and Appendix N for additional information.
2488	2	galer@inlandpower.com	N/A	The loss of barging would directly raise costs for farms, reduce jobs, and cause air quality issues for Eastern Washington communities that already face an uphill battle with greenhouse gasses and smog	The EIS evaluates the costs, and air quality and greenhouse gas emissions effects of modal shifts in shipping wheat from barges to road- and rail-based methods under MO3. Section 3.10.3.5 finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. Additionally, Section 3.8.3.5 describes that the loss of barging would result in up to a 53 percent increase in CO2 emissions (0.06 MMT CO2) relative to the No Action Alternative. The analysis additionally describes air pollution effects associated with increased potential for fugitive dust due to exposed riverbed along the lower Snake River.
2488	3	galer@inlandpower.com	N/A	Inland Power, along with all other Washington utilities have been charged with becoming carbon-neutral by 2030 and 100 percent carbon-free by 2045. The lower Snake River dams are essential to reaching the Northwests clean energy goals.	Consistent with the comment, the EIS finds that replacing hydropower generation from the four lower Snake River dams would increase carbon dioxide emissions. See Section 3.8.3.5 at pages 3-1009-1010 in the draft EIS. While the EIS finds that it would take even more renewable resources to replace the four lower Snake River dams generation while the region is retiring coal plants, the question of whether the dams are essential in reaching Northwest clean energy goals was not addressed in the EIS. See Section 3.7.3.5, Potential Replacement Resources And Associated Costs at pages 3-904-905 and Table 3-160 in the draft EIS.
2488	4	galer@inlandpower.com	N/A	These dams also help us safely add intermittent renewables, like wind and solar power, to the grid. The hydroelectric turbines at the dams can very quickly fill in the gaps when the sun doesnt shine and the wind doesnt blow, keeping the grid balanced	The statements that the four lower Snake River dams enhance the ability of the power system to integrate new renewables and to ramp up to meet load are consistent with the findings of the EIS. See draft EIS, Section 3.7.3.1, Integration Services at page 3-832 and Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907.
2488	5	galer@inlandpower.com	N/A	I urge you to strongly consider the numerous negative results that would occur should these vital dams be removed. Our state would suffer greatly from an economic, energy, job, agricultural, trade and environmental standpoint.:	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. 2494	1	harryrjag@gmail.com	N/A	Attached are my comments on Columbia River System Operations Draft EIS	Unfortunately, the co-lead agencies did not receive an attachment with this submittal. However, this commenter did also submit comments at a public meeting, which is listed as Comment Letter 4711. Please see comments and responses located at 4711.
2494	2	harryrjag@gmail.com	N/A	Attached are my comments on Columbia River System Operations Draft EIS	See response to Comment 2494-1.
2500	1	paulk@highlinegrain.com	N/A	Our economies are not prepared to function with the loss of barging on the Columbia and Snake rivers. Our highway, rail, and grain elevator networks would need over $1.1 billion in capital investments to adapt. This includes hundreds of miles of short-line rail track that have been abandoned; new rail; major highway improvements; and retrofits for grain elevators that do not have rail-loading capabilities. Our local businesses simply cannot manage either the expense or the long-term shock a transportation interruption of this nature would cause.	The Navigation and Transportation Section 3.10 reflects the adverse effects of implementing MO3 including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. There would need to be investments in infrastructure if dams are breached, both public and private sector investment in the absence of river navigation. These infrastructure improvements are discussed in section 3.10 of the EIS. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent).
2500	2	paulk@highlinegrain.com	N/A	A shock to our transportation system would ensure a dramatic increase in the cost of freight for not only our patrons, but all those who farm in the State and region. Grain suppliers and shippers that our economies depend on will likely see an increase in transportation and storage costs by 50 to 100% if barging is lost as a transportation option. In an industry where $5.00 per bushel is the current break-even cost, the loss of barging could increase transportation and storage costs from $0.40 per bushel to up to $0.80 per bushel. Dam removal would will dramatically impact our region's global competitiveness, ensure massive job loss in struggling rural communities, create costly and immediate increases in infrastructure damage (State and county roads and rail), and bankrupt countless family farms	The EIS acknowledges that rail rates may increase if the Lower Snake River dams are breached, and evaluates three rate scenarios. The EIS finds that average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are much higher, depending on their specific location and other conditions. As described in the Navigation and Transportation section of the EIS (Section 3.10), the navigation evaluation in EIS found that transportation costs for wheat in the Palouse Region would increase from $0.07 to $0.24 per bushel. The Navigation and Transportation Section 3.10 reflects the adverse effects of implementing MO3 including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Rail ton-miles would increase by as much as 86 percent (when rail rates are not assumed to increase) or decrease by 2 percent (when rail rates increase by 50 percent).
2501	1	mnaaldrich1@aol.com	N/A	One thing seems to be missing in the discussion that is what were the numbers of salmon in the river without the dams? I am not a fisherman but have noticed that each year the fishing season limits change, with the dams in place. How do we know things have changed with the dams in place? People have been tracking the orkas in the ocean. The orka population also increases and decreases over time. How do we as citizens of the Pacific North West and particularly the Snake River area know that breaching the dams will help or hinder the okras?	Estimates of salmon populations before the construction of dams vary widely and were dependent on a number of environmental and human induced factors. A good reference is from the Independent Science Advisory Board (see ISAB 2015-1). Consistent with NEPA requirements, this EIS did not address historic salmon populations, but compared the effects of the alternatives to baseline conditions established in 2016 when the EIS process began, as the agencies are comparing changes in operations and configuration of each alternative to the No Action Alternative. There are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Additional details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS.
2506	1	garryr@inlandpower.com	N/A	The loss of barging would directly raise costs for farms, reduce jobs, and cause air quality issues for Eastern Washington communities that already face an uphill battle with greenhouse gasses and smog.	The EIS evaluates the costs, and air quality and greenhouse gas emissions effects of modal shifts in shipping wheat from barges to road- and rail-based methods under MO3. Section 3.10.3.5 finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. Additionally, Section 3.8.3.5 describes that the loss of barging would result in up to a 53 percent increase in CO2 emissions (0.06 MMT CO2) relative to the No Action Alternative. The analysis additionally describes air pollution effects associated with increased potential for fugitive dust due to exposed riverbed along the lower Snake River.
2506	2	garryr@inlandpower.com	N/A	Inland Power, along with all other Washington utilities have been charged with becoming carbon-neutral by 2030 and 100 percent carbon-free by 2045. The lower Snake River dams are essential to reaching the Northwests clean energy goals.	The EIS recognizes the relevance of the Washington Clean Energy Transformation Act, among other regional emissions reductions targets, in Section 3.7 Power and Transmission analysis and Section 3.8 Air Quality and Greenhouse Gases emissions analysis. The analyses evaluates the extent to which the CRSO EIS Multiple Objective alternatives influence the ability of the region to meet these objectives, finding that Multiple Objective Alternative 3, which includes breaching the four lower Snake River dams, would make these goals more difficult to meet.
2506	3	garryr@inlandpower.com	N/A	These dams also help us safely add intermittent renewables, like wind and solar power, to the grid. The hydroelectric turbines at the dams can very quickly fill in the gaps when the sun doesnt shine and the wind doesnt blow, keeping the grid balanced	The statements that the four lower Snake River dams enhance the ability of the power system to integrate new renewables and to ramp up to meet load are consistent with the findings of the EIS. See draft EIS, Section 3.7.3.1, Integration Services at page 3-832 and Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907.
2506	4	garryr@inlandpower.com	N/A	I urge you to strongly consider the numerous negative results that would occur should these vital dams be removed. Our state would suffer greatly from an economic, energy, job, agricultural, trade and environmental standpoint.	The EIS evaluated benefits and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. The EIS does not employ a cost-benefit framework for decision-making. Instead, the EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most of the other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
2519	1	dickz@inlandpower.com	N/A	As a hay and dairy producer, the four lower Snake River dams are vital for the continued survival of my familys business. These dams provide the only source of irrigation for tens of thousands of acres in eastern Washington.	Your statements concerning land irrigated from Lower Snake River dam pools is consistent with the description in the EIS. In Region C under the MO3 alternative this analysis assumes that pumps are unable to deliver water to estimated at 48,000 acres. Please see Section 3.12 and Appendix N for additional information.
2519	2	dickz@inlandpower.com	N/A	The loss of barging would directly eliminate sales avenues, raise costs for farms, reduce jobs, and cause air quality issues for Eastern Washington communities that already face an uphill battle with greenhouse gasses and smog	The EIS evaluates the costs, and air quality and greenhouse gas emissions effects of modal shifts in shipping wheat from barges to road- and rail-based methods under MO3. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
2529	1	Anthony Umek	AKU Enterprises, LLC	1. RELIABLE ELECTRICITY : Hospitals, security, defense and travel (airports; traffic signals, etc) require reliable electricity. a. HYDRO POWER - Utah State in a recent study stated: "Hydropower is physically reliable because it is more efficient than many other energy sources and can run consistently with little maintenance, making it an ideal source of baseload power. For decades, hydropower has proven to be a source of renewable energy that millions of Americans rely on to meet their daily electricity needs. "Hydro dams are key to meeting Washington State's Clean Energy Transformation Act. b. WIND POWER - Per the US Dept. of Energy overall "Capacity Factor"~ 33%. Existing battery storage is inadequate to support 24hr reliability (Ref ENER GY. GOV documenting a high performance 240 MWh lithium battery can produce 100% power for only 4 hours; at $380/ KWh). c. SOLAR POWER - Photovoltaic Capacity factor~ 20%. Battery storage issue same as wind power . d. ELECTRICAL GRID OPERATION. Utah State University documented a study and found wind is extremely variable in the short term. When looking at energy production within 30 ta 90 minute intervals, there are frequently swings of 10 percent electricity output. Grid operators must monitor the supply and demand and must be able to mitigate the swings in wind power output on timescales as short as ten seconds. More variability in electrical production due to wind power mean s that grid operators must monitor the supply and demand of electricity more closely. Not only do high levels of variability make it more difficult for grid operators to keep supply and demand in constant balance, they can also strain the infrastructure of the grid.	The commenter's suggestion that hydropower is a reliable source of power is consistent with the findings of the EIS. The findings of the power replacement resources indicated that more capacity for zero-carbon resources (e.g., solar) were needed to address lower capacity factors, consistent with the commenter's concern. The ability of hydropower to aid in grid stability and the integration of renewable power, as described by the commenter, is also consistent with the descriptions and analysis of the EIS as described in the Bonneville Transmission System Reliability and Operations subsection of Sections 3.7.3.3 through 3.7.3.6 and in Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the Draft EIS.
2529	3	Anthony Umek	AKU Enterprises, LLC	2. ECONOMIC IMPACTS- The Lower Columbia-Snake River irrigators farm about 350,000 acres, and the irrigated agriculture industry yields over $1 billion annually to household incomes - the impact felt throughout Eastern Washington and Oregon, as well as in Seattle and Portland . Snake River dams provide irrigation for high-value crops on 60,000 acres of prime farmland . Water levels in a free-flowing river are not stable enough to provide reliable irrigation.	There is a physical limitation to delivering water to these lands in the absence of the dams. Breach of the dams has the potential to drop surface and groundwater levels up to 100 feet and it is not possible from an engineering or cost standpoint to replace the delivery mechanisms, nor do the co-lead agencies have the authority to do so currently. Please see Section 3.12 and Appendix N for additional information.
2529	4	Anthony Umek	AKU Enterprises, LLC	3. IMPACTS ON FARMERS AND OTHERS USING BARGING FOR TRANSPORT OF CRITICAL FOOD AND MATERIALS: Breaching the dams would require adding over 165,000 tractor trailer trucks, annually, currently served by tugs/barges on the Snake River. Impacts include: a. Existing roadways are not adequate to handle traffic in winter; resulting in projected accidents, injuries and fatalities. Significant $ to upgrade. b. Logistics of loading, unloading, fueling and maintaining the added truck traffic. c. Carbon foot print of the added highway traffic. d. Impacts on farmers and businesses (and job losses) caused by inclement weather, highway closures, accidents, etc. that would hinder goods from reaching market.	The EIS analysis concurs that there would be significant investments needed in regional infrastructure to continue transportation of agricultural products, which would include additional potential impacts to farmers. The commenter's concern that breaching of the four lower Snake River dams will cause increased emissions is also consistent with the findings of the EIS both for traffic increases and replacement sources for power. The EIS considers a zero-carbon replacement resource portfolio to replace the capability of the four lower Snake River dams in Section 3.7.3.5, Potential Replacement Resources and Associated Costs. However, the Draft EIS also found that even assuming this zero carbon portfolio was selected, net GHG emissions may increase because existing fossil-fuel generation plants would also increase generation to maintain regional reliability. The EIS relies on high-quality, the best, currently available information to evaluate the tradeoffs associated with dam breach under MO3. The Navigation and Transportation Section (3.10) reflects the adverse effects of implementing MO3, including discussions of transportation mode capacity and cost of grain transport. The EIS also evaluates the additional transportation infrastructure investments and associated costs that would be required, as well as the increases in air emissions that would occur. The EIS finds that truck ton-miles may experience an increase of 19 percent to 84 percent under MO3 when compared to the No Action Alternative, depending on the rail rate increases that occur. The EIS analysis found that truck trips would increase between 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. Similarly, Section 3.10 also describes increased safety concerns from the additional truck traffic resulting from MO3.
2529	5	Anthony Umek	AKU Enterprises, LLC	6. SALMON & ORCA SURVIVAL: The strategic objective of increasing salmon and ORCA survival; not just in the Snake River system, but more broadly, needs to consider all factors, including: 1. Salmon survival rates through these dams exceed 95%. 2. NOAA: Quoting from an August 2015 study by the National Oceanographic and Atmospheric Administration (NOAA): "Several observations have documented behavioral shifts in salmon that are likely due to warming climate trends over the past half century. In fall Chinook salmon from the Hanford Reach of the Columbia River, spawn date has shifted one week later since 1950, during a 2C period of warming (Hayes, et al. 2014). Salmon from 67 rivers on both sides of the Atlantic have shifted smolt timing approximately 2.5 days earlier/decade (Otero et al. 2014). Unusual catches of Atlantic salmon indicate range shifts in the north Atlantic have reached as far north as Svalbard (Jensen et al. 2014)." 3. A paper: "Environmental factors influencing freshwater survival and smolt production in Pacific Northwest Coho salmon (Oncorhynchus kisutch)", by PW Lawson, EA Loggerwell, et al; includes the following quote: "Climate variability is well known to affect the marine survival of Coho salmon (Oncorhynchus kisutch) in Oregon and Washington. Marine factors have been used to explain up to 83% of the variability in Oregon coastal natural Coho salmon recruitment, yet about half the variability in Coho salmon recruitment comes from the freshwater	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery goals set under ESA Section 4(f) for the strategic objective of increasing salmon and orca survival are separate and distinct from goals associated with the analysis of alternatives under NEPA. The co-lead agencies agree that a number of factors, including ocean conditions and climate change, as mentioned by the commenter, will continue to influence salmon survival. While none of the alternatives would affect ocean conditions, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of ocean conditions in the return of adult salmon and steelhead (Peterson et al. 2019). The co-lead agencies analyzed the effects of the operation, maintenance, and configuration of the CRS projects on resources affected by the CRS, including the potential to improve conditions for ESA-listed species. The co-lead agencies also looked at the cumulative effects of other actions, including harvest in Chapters 6 and 7 of the EIS. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. Information on water quality, including temperature, can be found in Sections 3.4 and 7.7.3. Climate effects are discussed in Chapter 4.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				life phase of the life cycle. This seeming paradox could be resolved if fresh water variability were linked to climate and climate factors influencing marine survival were correlated with those affecting freshwater survival. Effects of climate on broad-scale fluctuations in freshwater survival or production are not well known. We examined the influence of seasonal stream flows and air temperature on freshwater survival and production of two stock units: Oregon coastal natural Coho salmon and Queets River Coho salmon from the Washington Coast. Annual air temperatures and second winter flows correlated strongly with smolt production from both stock units. Additional correlates for the Oregon Coast stocks were the date of first fall freshets and flow during smolt outmigration. Air temperature is correlated with sea surface temperature and timing of the spring transition so that good freshwater conditions are typically associated with good marine conditions." " .....Off the Oregon Coast, a year-long sequence of events beginning in the winter before smolts enter the ocean can explain over 70% of the variability in hatchery smolt survival (Logerwell et al. 2003). Ocean environmental indices explain 75% (Lawson 1997) to 83% (Koslow et al. 2002) of adult recruitment of naturally spawned Coho salmon from Oregon .	
2529	6	Anthony Umek	AKU Enterprises, LLC	4. PUGET SOUND POLLUTION AND SALMON & STEELHEAD - The precise effects of chemical pollution on salmon and steelhead in Puget Sound are not well known, according to Sandie O'Neill, a toxicologist with the Washington Department of Fish and Wildlife, but there is no doubt that Puget Sound salmon and steelhead are being exposed to chemicals that can affect their well-being. Studies have found that concentrations of some toxics are high enough to trigger adverse health effects in 18 to 100 percent of the juvenile Chinook salmon collected from four of the 11 river estuaries sampled, as well as Lake Washington . Known as persistent bioaccumulative toxics, or 'PBTs', these compounds are also high enough to trigger adverse health effects in a third of the juvenile steelhead collected from one of the three river systems. Possible effects range from impaired growth to suppressed immune function. Researchers also found that juvenile Chinook tissues contain a mixture of pharmaceutical, personal-care and industrial compounds. One study of Chinook coming out of five Puget Sound streams revealed that several drugs designed for humans (e.g., anti depressants, heart medications and antibiotics) were in concentrations likely to affect behavior, metabolism and potentially other functions.	We agree that there are many effects to salmon and steelhead populations outside the operation and maintenance of the Columbia River System dams, including toxics. This EIS is on the effects of the operations, maintenance, and configuration of the CRS and therefore, pollution in the Puget Sound outside the scope of this analysis. However, research continues to evaluate the magnitude of these effects in the Sound. For more information see the NOAA website at: https://www.nwfsc.noaa.gov/research/index The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions would generally continue to ensure compliance with the ESA. Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the CRS project. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
2533	1	slonecker_b@heritage.edu	N/A	The "usual and accustomed places" protected in the various treaties with Plateau tribes have been flooded by the Columbia system dams, including those on the lower Snake River. Those dams were constructed without tribal consent. In fact, they were constructed over the vocal opposition of Plateau tribes. For over a hundred years (since the 1905 decision in United States v. Winans) and as recently as 2019 (see the Cougar Den decision), federal courts have consistently ruled that the terms of the treaties must be interpreted according to how tribal signatories would have understood them in the 1850s. There has never been doubt that the construction of the dams directly contradicted the desires of tribal signatories; the United States Senate confirmed that in hearings prior to the construction of The Dalles Dam and it has been confirmed by tribal leadership repeatedly, across many generations. The Yakama Nation Tribal Council reaffirmed that view just last year. I believe that the Endangered Species Act warrants removal of the lower Snake River dams. But I recognize that decisions made under the Endangered Species Act are always subject to some degree of subjectivity and interpretation of complex ecological evidence. But this issue should not be resolved on the basis of the Endangered Species Act. Dam removal should immediately proceed (not just on the Snake River but on the entire Columbia River system) because it violates sacred treaties, signed in good faith and subsequently ignored by the flooding of protected sites. In lieu sites are not adequate; cash payments are not adequate. "ALL usual and accustomed places" are protected - not some. Until that basic fact is the starting point for conversations about the future of the Columbia River, Northwest tribes have little reason to trust the goodwill of the U.S. federal government.	The co-lead agencies are committed to fulfilling their treaty and trust obligations and providing early, open, transparent and meaningful consultation. See Sections 2.3 and 9.3.2. The co-lead agencies look forward to continuing to consult on the EIS, which covers changes to the water management of the existing 14 projects on the Columbia and lower Snake Rivers. The co-lead agencies recognize these obligations while also acknowledging that construction of the Federally authorized CRS projects directly impacted many of the regions Tribal communities. For this EIS, the No Action Alternative describes the operations, maintenance, and configuration of the CRS, from September 30, 2016, the date the Notice of Intent to Prepare the EIS was published in the Federal Register. As an ongoing action under NEPA, the No Action Alternative considers what would happen if the CRS continued to be operated, maintained, and configured with no change. Breaching the earthen embankments of the four lower Snake River dams was analyzed as part of MO3. It was not selected as the Preferred Alternative because while it improved passage and survival of certain ESA-listed fish, it did not meet five other objectives of the EIS, nor the Purpose and Need Statement. It also had significant adverse effects to the regional economy and social impacts. Throughout this EIS process, the co-lead agencies have analyzed impacts of the ongoing operation and maintenance of the CRS to treaty-reserved rights and associated resources. This analysis addresses how those rights would be impacted by the potential alternatives including how measures could affect fish abundance that may affect the U.S. v. Oregon Fishery Management Agreement, and the extent to which treaty rights and Tribal resources would be protected and enhanced. The Preferred Alternative includes actions to benefit ESA-listed fish as well as lamprey, and these actions also benefit Tribal interests and treaty resources. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery determinations are ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve more parties than just the co-lead agencies across the region that have an influence and impact on ESA-listed species.
2533	2	slonecker_b@heritage.edu	N/A	Second, the EIS is scathing in its criticism of dam removal's economic impact while simultaneously being startlingly unimaginative in considering alternative infrastructure projects that would mitigate the economic costs described in the EIS. Each of the major impacts of dam removal has a clear set of mitigation projects that would both address the economic concerns of the region's business and agricultural leaders and honor tribal sovereignty and ecological integrity. The United States has the world's most talented engineers; turned loose on the problem of designing an ecologically sound and socially conscious Columbia River system that continues to provide irrigation, transportation, and energy services, these engineers would make the region the world's leader in green design. Efficient rail; effective pumping; solar energy - these are just starting points in creating a system that would provide an incredible economic boost to the region. That would require a massive federal investment. But for the reasons I've outlined above regarding treaty rights, that massive federal investment is necessary and in the best interests of all stakeholders. This region has always been built on massive federal investment - that was true in the 19th century, as the federal government gave away land to promote settlement, and it has been true into the 20th and 21st centuries, as the federal government built Hanford and now labors to clean it up. As a region, we are a federal project - ever since the United States entered this region, we have been. But dam removal and the subsequent investments in new infrastructure design would place us in a position to make the federal northwest a project that simultaneously makes good on promises made to indigenous peoples.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Chapter 2 describes the process of developing the actions for consideration and development of alternatives and was based on considerable public, cooperating agency, Tribal and co-lead agency input. The scope of the EIS include alternatives to operations, maintenance and configurations of the 14 Federal projects. Under MO3, construction of new infrastructure to replace the lost purposes of the existing infrastructure or to mitigate for the loss of Federal benefits was considered where there are existing Federal authorities. However, in order to regain the full benefits of these lost Federal services, the co-lead agencies identified mitigation measures that are outside the authority of the co-lead agencies that would need to be taken by other entities to alleviate the loss associated with de-authorization of Federal projects.
2533	3	slonecker_b@heritage.edu	N/A	Third, the U.S. Army Corps of Engineers should more directly account for why this decision so flatly contradicts the logic that undergirded its decision to block the coal port that violated the treaty rights of the Lummi Nation. The fact that the dams exist and the coal port was proposed is inadequate. The coal port was blocked because it violated treaty protected fishing rights; the dams should be removed for the same reason. If the same agency, within the span of just a few years, reaches such contradictory decisions, they lose credibility. And I think that the agency should at least publicly acknowledge its startling about-face. Federal courts have a string of rulings about treaty interpretation - decisions stretching back over a hundred years but also including the most recent rulings in federal Indian law - that allow for a dam removal decision that is legally sound and socially just. It only requires the courage of today's judges to connect dam removal (which has too often been addressed solely through the lens of species renewal) to that precedent. "All usual and accustomed places" means ALL, including those fishing sites that have been flooded by these dams and would reemerge with their removal.	Development of the Preferred Alternative in the CRSO EIS does not contradict the U.S. Army Corps of Engineers logic or decision in 2016 that Federal authorization of a private entity's proposed bulk commodity export terminal (Gateway Pacific Terminal) would impermissibly impair the Lummi Nations reserved treaty rights to access Tribal usual and accustomed places to fish. The underlying facts supporting that agency decision are distinct, and were raised by the tribe for agency consideration under different, unrelated authorities. The fact that a proposed export terminal was found to infringe on a tribes right to access a specific usual and accustomed place does not contradict the development of the Preferred Alternative to continue to operate the existing CRS projects in this NEPA analysis. The co-lead agencies are committed to upholding their treaty and trust obligations in all of their decisions, including any assertions of potential impairment of treaty-reserved rights. Treaty specific information is included in Section 3.17 as well as Chapter 7. As stated in that section, the congressionally ratified treaties bind have the force and effect of federal law. The co-lead agencies recognize and respect that fact. Indeed, the co-lead agencies included "Protecting Native American treaty and reserved rights and fulfilling trust obligations for natural and cultural resources throughout the environment affected by the Columbia River System operations" as a purpose in the Purpose and Need Statement in Chapter 1 to ensure treaty obligations were a key consideration in decision making. The co-lead agencies are also engaging in government-to-government consultation with the Tribes, and several Tribes are cooperating agencies on the CRSO EIS.
2538	1	N/A	N/A	A couple questions: In MO2, I was surprised to see the projected cost estimate of $850M for the McNary surface juvenile collection and bypass system. Did any of the parties involved communicate with Grant County PUD on the design or cost of the surface bypass project they did at Rocky Reach dam back in 2001-2002? Other than reducing juvenile fish predation by terns at John Day, was scoring given to aggressively reducing predation by pinnipeds?	The commenter is correct about the cost for the juvenile collection and bypass system. This cost was identified as the best alternative at the time of the development of the alternatives, however as noted in the EIS (see Section 3.7.3.4, Electricity Rate Pressure), the results of this analysis suggest that it would be much more cost effective to continue the use of fish screens and use the turbine bypass system to collect fish if transport from McNary is desired.
2559	1	Michael Freepons	Benton Rural Electric Assocation	Climate change is impacting the ocean environment where salmon spend the majority of their lives, and the DEIS does not acknowledge the beneficial impacts of the carbon-free electric generation of the lower Snake River dams in combatting climate change.	The decline of salmon populations is complex and recovery of those species will take collaboration between various agencies including NOAA and the Tribes. The co-lead agencies acknowledge that the ocean environment is a contributor to the decline in salmon populations that is beyond the scope of the CRSO EIS. While none of the alternatives would affect ocean conditions, we recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of this environment in the return of adult salmon and steelhead (Peterson et al. 2019). As such two of the models used in these analyses, NMFS Lifecycle and CSS models, use metrics of ocean productivity to predict adult returns. The carbon-free attributes of the Federal hydropower system are described in the Air Quality Section of the Draft EIS (Section 3.8). The analysis includes the effects to GHG emissions resulting from changes in hydropower generation for each alternative, including breaching the Lower Snake River dams in MO3.
2559	2	Michael Freepons	Benton Rural Electric Assocation	According to the DEIS, the loss of the lower Snake River dams would double the region's risk of blackouts. However, this risk of blackouts does not factor in the loss of nearly 6,000 megawatts of electricity generation in the region due to the closure of coal plants, which is the result of recent state legislative action. A reliable electricity supply is critical now, and our region's electric utility industry faces significant challenges in the coming years in maintaining a reliable system. The carbon-free capacity provided by the lower Snake River dams has never been more important to maintaining a reliable system and avoiding outages for this critical infrastructure, and will become even more important in the future.	The statement that without resource replacement, regional power reliability would decline under MO3 is consistent with the findings of the EIS. See Draft EIS, Section 3.7.3.5, Effects on Power System Reliability, at page 3-903; see also Appendix H, Table 2-1. The EIS also finds, consistent with this comment, that increasing retirement of coal power plants would adversely affect regional power reliability (see Draft EIS Section 2.3 of Appendix H, Sensitivity of LOLP to Assumptions about Coal Capacity). The importance of hydropower for regional emissions is also consistent with the findings of the EIS. The measure to breach the four lower Snake River dams that was evaluated in MO3, was not included in the Preferred Alternative identified in the Draft EIS. The effects of the Preferred Alternative on power are described in Section 7.7.9 of the Draft EIS. Overall, hydropower would decrease relative to the No Action Alternative under the Preferred Alternative. However, because of the shape of the remaining hydropower generation in the Preferred Alternative, the loss of load probability was essentially the same as that of the No Action Alternative.
2559	3	Michael Freepons	Benton Rural Electric Assocation	Energy shortages are not just about reliability and outages. The last energy shortage in the early 2000s did not cause brownouts or blackouts in the Northwest, but the Northwest lost thousands of jobs as energy bills increased rapidly and companies were forced to shut down. The DEIS notes that replacing the electricity production of the lower Snake River dams with carbon-free generation in order to comply with state targets would result in a 50% increase in wholesale electricity prices. Those costs will be passed on to Northwest residents, putting greater hardships on people already struggling to make ends meet, and on businesses trying to compete in a global economy. The Washington State legislature passed the Clean Energy Transformation Act in 2019, which established greenhouse gas emission targets for the electricity sector. The lower Snake River dams are essential to reaching those clean energy goals. More than 1,000 average megawatts of affordable, carbon-free electricity are produced by the lower Snake River dams.	The EIS discusses the West Coast energy crisis of 2001 mentioned in the comment (see 3.7.2.11 Regional Electricity Rates). The statement that wholesale electricity rates would increase up to 50 percent to replace lost hydropower generated in MO3 (which includes breaching of the four lower Snake River dams) is consistent with the findings of the EIS. See Section 3.7.3.5, at 3-918 to 924 in the Draft EIS; see also Table 3-166. The Environmental Justice analysis in Section 3.18.3 of the EIS provides further detail on potential disproportionate effects to Tribal, low-income and minority populations under MO3. Regarding the costs to regional rate payers, the EIS examined the rate effects of these replacement resources in Section 3.7.3.5, Social and Economic Effects of Changes in Power and Transmission. The EIS recognizes the relevance of the Washington Clean Energy Transformation Act, among other regional emissions reductions targets, in Section 3.7 Power and Transmission analysis and Section 3.8 Air Quality and Greenhouse Gases emissions analysis. The analyses evaluates the extent to which the CRSO EIS Multiple Objective alternatives influence the ability of the region to meet these objectives, finding that Multiple Objective Alternative 3, which includes breaching the four lower Snake River dams, would make these goals more difficult to meet.
2559	4	Michael Freepons	Benton Rural Electric Assocation	While the DEIS provides insight into why the preferred recommendation includes the flex spill, the Board has concerns about the significant costs, increased carbon emissions and unproven benefits of increased spill. The significant disparity in fish survival based on the two models used to analyze the various alternatives considered in the DEIS highlight the unproven results associated with increased spill. Fish survival is important, and the Board feels strongly that investments should be prioritized based on proven measures with verifiable results.	The co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective flex spill can be at increasing salmon and steelhead returns to the Columbia Basin.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Appendix R, Part 2 describes the principles for implementation of the flexible spill operations and guidance for adaptive management. One of the principles focuses on federal power system benefits, which will be as determined by Bonneville Power Administration. The understanding is that Bonneville must, at a minimum, be no worse financially compared to the 2018 spring fish passage spill operations ordered by the Court. This principle is directly related to Objective 5 of the CRSO EIS: Provide an adequate, efficient, economical and reliable power supply that supports the integrated CR Power System. The co-lead agencies have determined that the Preferred Alternative meets this Objective. In addition, the Preferred Alternative places additional rate pressure for wholesale power rates of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs it has significant control. The Preferred Alternative does not meet the objective for greenhouse gas emissions across the region. Hydropower generation would decrease resulting in increased generation from existing gas and coal plants resulting in increased greenhouse gas emissions.
2559	5	Michael Freepons	Benton Rural Electric Assocation	We recognize the scope of the DEIS is primarily focused on the Columbia River System operations. However, not enough focus and attention is being placed on the ocean, which has a greater impact on adult returns. Salmon spend between 75% to 80% of their lives in the ocean, and there are growing concerns about salmon survivability in the ocean. The Intergovernmental Panel on Climate Change has warned that climate-driven changes have become a major threat to marine life in ocean ecosystems. These changes are depleting the ocean waters of oxygen, and poisoning them with carbon, heat and acidity. Marine biologists have recently noted near-synchronous declines in worldwide salmon populations.	The Draft EIS describes and acknowledges the multitude of factors that affect salmon and steelhead throughout their life cycle in the Affected Environment. As the commenter acknowledges, this Draft EIS analyzes the effects of configuration, maintenance, and operation of the CRS projects and those effects were analyzed in Chapter 3.4. The scope of the Draft EIS focuses on the area affected by the alternatives presented for operation and configuration of the CRS projects. While none of the alternatives would affect ocean conditions, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of ocean conditions in the return of adult salmon and steelhead (Peterson et al. 2019). The co-lead agencies analyzed the effects of the operation, maintenance, and configuration of the CRS projects on resources affected by the CRS, including the potential to improve conditions for ESA-listed species. The co-lead agencies also looked at the cumulative effects of other actions, including harvest in Chapters 6 and 7 of the EIS. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm.
2559	6	Michael Freepons	Benton Rural Electric Assocation	Further, recent concerns regarding the southern Puget Sound resident orca recovery have been erroneously focused on the lower Snake River dams. It is well documented that the Puget Sound suffers from high levels of toxicity which affect both pacific salmon and orcas. Salmon in the Puget Sound have been found with measurable levels of antidepressants, nicotine, herbicides and even cocaine in their systems. Because orcas eat large amounts of salmon, these toxins become concentrated in their fat. These substances may be passed along to orca calves through their mothers' milk. More attention must be placed on repairing the Puget Sound, so that it is an area suitable for healthy salmon and orca populations. We again appreciate the collaborate work that went into the DEIS, which included significant input from federal agencies, Native American tribes and the states of Oregon, Washington, Idaho and Montana. The Board of the Benton Rural Electric Association is pleased that the DEIS recognizes the importance of the lower Snake River dams and recommends not breaching the lower Snake River dams as the preferred alternative.	Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the CRS project. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state, and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
2561	1	mayor@clarkston-wa.com	N/A	Clarkston, WA is a city that is bordered on two sides by the Snake River as it makes a sweeping curve and moves west to join the Columbia River. Our waterfront is regulated by the Army Corps of Engineers. The City of Clarkston is very small, approximately 2 square miles. Forty-two of our City parcels are exempt from taxes. These include churches and other tax exempt entities. This does not include three elementary schools, Clarkston High School and Clarkston School District offices. Our median household income is $35,000 per year, with median value of housing at less than $140,000. More than 50% of housing is rentals. Only 16% of our population has a bachelors degree. We are not a wealthy community. We derive 45% of our City revenue from sales tax. Any downturn in the economy has a huge impact on our ability to generate revenue for needed services. Dam breaching would severely and negatively impact our economy. When considering dam breaching, not only the initial but the long-term impacts must be considered. Restoring salmon habitat is a one-dimensional solution with dam breaching but creates multiple impacts for communities like Clarkston, and Asotin WA and Lewiston, ID. The financial impact with dam breaching will be a huge burden and negative impact to our communities in the Lewis Clark Valley region. Businesses, whether agricultural, or riparian have been cultivated for many years upon the rivers present flow. For the Lewiston Clarkston Valley to suddenly have the level of the river altered will be changing an entire culture built upon the current operational level of the Snake River. You have all the documentation and statistics that speak to the Snake and Columbia Rivers and the success of the levee system in Lewiston and Clarkston. You know the amount of agricultural products that are barged down our river, the switch to truck traffic to carry those products to market, and the future negative impact on our roads and infrastructure. I want to convey to you what Clarkston would experience with dam breaching. The levee system that was put in place by the Corps drastically changed the landscape along the Snake River. The resulting trail system is used daily by thousands of residents and visitors walking, running, pushing strollers, and riding bicycles. Local schools host cross-country events on the green belt trails behind our high school that include many Eastern Washington high schools. The lower water level with dam breaching would cause deterioration in the levee system and create a wasteland with no water available to irrigate the green belt. The resulting dust accumulation from areas formerly covered by water will have a detrimental impact on the environment and health hazards for our vulnerable population. The increase in dust will have a detrimental affect on the health of our community. We currently have a population that can barely afford regular medical care. Dam breaching would lower water levels from 41 feet to 10 feet at our Waste Water Treatment Plant outfall line and to only six feet where our diffusers are located. TMDL (Total Maximum Daily Load) and temperature limits would have to be reassessed with WWTP modifications and stricter regulations and testing by Department of Ecology. The City of Clarkston completed a $12 million dollar upgrade to our Waste Water Treatment Plant in 2012. These bonds will not be paid off until 2043. Clarkston cannot afford to borrow new money to mitigate the impacts of new water quality requirements due to dam breaching or further burden our residents with increased Waste Water Treatment Plant utility fees. Riparian activities that support our economy Cruise Boat Visits Jet boat excursions Hotels, motels, restaurants 12 boat manufacturing related businesses located in the Lewis Clark Valley Breaching four dams would result in a lowered water level that would curtail many current recreational and tourism related activities on the river and negatively impact the recreation and associated businesses that benefit us as a City. The draw down in 1992 created ultra-low water levels and demonstrated the dramatic change we could expect with dam breaching. We are the hub for agriculture on the Palouse Prairie, north of us in the Moscow and Pullman area, and south of us on the Camas Prairie, towards Cottonwood and Grangeville, Idaho. The vast majority of our agricultural products are barged down the Snake River from the Lewis Clark Valley. Cruise Boats have had an increasing benefit to us with 18,839 visitors and 54 Cruise Boat visits in 2018. Plans are for more visitors in the future. Cruise Boats and Jet Boats contribute to a robust economy for our region. As we have learned more and more about the impacts of dam breaching, we realize that our community can expect a significant detrimental cascading financial effect to occur. It is our understanding that the fish returns are cyclical. Before we breach dams we need to look at degrading ocean conditions and impacts of increased shipping, environmental impacts of Seattles growth, and the entire North Pacific Coast. We have not heard any guarantees that dam breaching will increase fish populations. The concept behind including Snake River dam removal in alternatives is that fish passage will be improved. The number of adult fish returns in 2014 was phenomenal with 2.5 million fish passing through Bonneville Dam. If fish passage was the only factor affecting recovery, then returns should have increased every year after 2014. More spill occurred after 2014 and other improvements were put in place. But numbers went down. That clearly illustrates that factors beyond fish passage affect smolt-to-adult fish returns. The City of Clarkston is not in a position to make major sacrifices for negligible benefit. Clarkston and our regional community would be financially decimated due to the effects of dam breaching. The loss of current recreational opportunities, tourism business and economically reliable shipping of agricultural products to the world would be devastating. The EIS should properly address the significant negative financial impacts to our community and surrounding region when considering the dam breaching option.	The co-lead agencies have included a discussion of community concerns about the potential impacts of MO3 in the navigation section in section 3.10.3.5, in subsection under Regional Economic Effects called "City/Local Effects Associated with Changes in Commercial Navigation, Cruise Lines, and Ferry Operations" as well as under the Other Social Effects subsections. These sections describe potential regional economic as well as social and community impacts associated with dam breach. The EIS recognizes the short-term adverse effects to recreation visitation and values, including cruise and tour boats, and the associated impacts to the regional economy under MO3, which are described in Section 3.11.3.5. The EIS in Section 3.5.3.6 describes that there would be benefits to anadromous fish in the Snake River associated with the dam breaching under MO3. Effects to water quality (Section 3.4) and water supply (Section 3.12) from MO3 are also discussed in the EIS. Additionally, Section 3.18 discusses Environmental Justice and will be reorganized in the Final EIS to be clearer on cumulative impacts to communities of all alternatives. There are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm
2565	1	N/A	N/A	From my perspective, any desires to have things returned to "the way they were" must be both respected, and ignored. I do not pretend to know whether we are now in a better or worse situation than we had in the past, but we are certainly in a different one, and it is the norm to which we are all accustomed. Making major changes that would affect the lives and livelihoods of many people in order to achieve the desires of a few who wish to prioritize a historical vision over very real needs for power production, economical transportation, flood control, etc. is simply not rational. The dams are here, they serve a vital purpose, and they should remain. I would very much like to see a clear statement of how the competing objectives will be balanced when they come into conflict.	The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level. The EIS does not employ a cost-benefit framework for decision-making. This is because, consistent with National Environmental Policy Act (NEPA) analysis framework (see 40 C.F.R 1502.23), the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. Consequently, a focus solely on the monetized economic costs and benefits would exclude important tradeoffs associated with the alternatives communicated in the EIS, including effects on fish. Furthermore, the EIS evaluates the performance of the CRSO EIS alternatives with respect to multiple objectives, for example related to improving fish passage and survival, reliable power generation, and minimizing greenhouse gas emissions. Tables 7-1 and 7-55 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives. The EIS set forth eight objectives, which in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
2565	2	N/A	N/A	Further, I would like to see a cost analysis for implementing the changes proposed in the preferred alternative that clearly identifies where the required funding will come from (and what other actions will not be possible as a result).	Section 7.7.21 in the Draft EIS describes the cost analysis for the Preferred Alternative. In addition Appendix Q, Cost Analysis describes the costs of specific measures in more detail. As described in these sections of the EIS, funding to operate the system comes through multiple mechanisms, including Federal appropriations to cover system costs as well as revenue generated from the marketing and sale of hydropower.
2567	1	Sandshot69@Yahoo.com	N/A	lets build a fish canal along the river specifically for the fish to bypass the dams. Start it below Bonneville and run its all the way past the last dam.	Thank you for your comment and your idea. A wide array of measures were considered through the process of measures development and during the creation of alternatives for these analyses. Canal or pipe systems were discussed for fish transport but were determined as technically infeasible and eliminated from further consideration.
2573	1	kenboire@aol.com	N/A	There is one bothersome issue, "reintroduction." This document seems inadequate regarding treatment of reintroduction of salmon above Grand Coulee Dam and installation of fish passage at Grand Coulee and Chief Joseph Dams. Because the concept of reintroduction is casually dismissed, this document disregards potential measures that could conceivably make up the most likely, most productive, most acceptable, most economic means of	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				increasing salmon stocks. Mitigation does not have to be in the same stream and reach as losses. By opening the basin above Grand Coulee, historical critical fish habitat would be accessible for reintroduction of anadromous stocks. The reasons given for not dealing with this potential come across as saying Well we dont have the data, we dont know the science, we don't want to do it now, it would be too much work but we can just figure it out later. A casual look at practically any map quickly reveals the amount of river basin and habitat that would be added above Grand Coulee in the USA and Canada would be huge and probably be more than what could be added in the USA by removal of the Snake River projects. Sure, challenges of international cooperation would be encountered but the USA and Canada have already rationally faced fisheries issues regarding Pacific Salmon in border waters of Washington and Alaska. International cooperation needs to be part of this solution and it is embarrassing to find that in the more than 20 years since ESA listing, the Corps, Reclamation, agencies, tribes and industry have seemingly not moved ahead an inch. It is equally embarrassing to discover how reintroduction has been quashed in this EIS because of apparent agency fixation on measures that have been under institutional study for longer than some careers. This is not to say the measures in the EIS are unsound, shallow, impractical or unworthy. They are clear, laudable, and scientifically derived. The nature of an EIS is that it is supposed to recognize problems, measure them, and evaluate alternative solutions. This document deals with long-standing listed species and should at least present a side-by-side comparison of reintroduction with other alternatives like the graphic treatment in Crosswalk", Table 2-12. Obviously more study will be required to do this and the EIS budget and timeline would require modification in order to include reintroduction and complete this EIS as a final report. But without this task the EIS is an empty document and someone might be able to argue it seems to fall short of the legal and scientific purpose. There must be a long history here. It is not a new issue. The challenges of passage, stocking and even reintroduction should have been hammered out starting in 1964 when some long-standing international dam issues were worked out for Canadian projects. Clearly somebody dropped the ball back then or sometime since. In over 50-years we should at least have a grasp adequate to proceed with a detailed consideration of reintroduction in this EIS. Reintroduction needs to be given serious treatment beyond saying agencies and interested regional sovereigns are developing a framework to address critical information gaps. As a minimum the EIS ought to include a budget and timeline of the in progress framework effort.	reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
2573	2	kenboire@aol.com	N/A	Speaking of reintroduction, the EIS states "Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS." One reviewer found this reasoning of incompatibility to be outrageous. Contrary to being incompatible, the concept of reintroduction is basic and essential as it could result in introduction of anadromous species in place of those made extinct by the lack of passage at Grand Coulee and other dams upstream of Grand Coulee. Reintroduction could require major construction but cannot be dismissed on the grounds it is beyond the scope of analysis of the operation of CRS as the EIS includes a dam removal alternative which itself is a major construction project well beyond any strictly operational option. Analysis of reintroduction could be so productive as to tamp down the desires for present day costly operational measures or modifications to the Snake River dams. In that sense, consideration of reintroduction belongs within this EIS and in all respects is not incompatible. Following is the EIS treatment From Page 2-79— Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. Here is a suggestion: The overall issue of reintroduction can probably be de-fanged for now. Pull the curtain back. Offer full disclosure. In the EIS, discuss the history of the blockage, what happened and why, what the upriver potential could be, what the institutional, political, cultural, etc. roadblocks are now, what the realistic opportunities and limits are. Commit to developing a summary plan of study including what is involved in getting the authority and resources to move ahead. Include a broad brush budget and critical path timeline as if this were a fresh start and expect it to reach decades into the future.	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps. This effort was initiated on June 23, 2020 when the co-lead agencies participated in a discussion with regional sovereigns concerning fish management in blocked areas.
2587	1	D. Beaman	N/A	The issues preventing salmon recovery are biological in nature and therefore applying mechanical solutions such as breaching or similar remedies will not work. Previous efforts in these regards have failed thereby disappointing you, me, generations of Native Americans, fishermen, Puget Sound orca and salmon everywhere. Future efforts at dam removal intended to increase salmon populations will also fail and additional lawsuits will continue to disappoint everyone including the hapless judge that history will hold responsible for any legal decision allowing the lower Snake River dams to be breached. Applying a biological approach rather than mechanical methods previously considered presents a primary and a few secondary testable hypothesis that would result in substantial repopulation of salmon if I am correct.	The co-lead agencies agree there are many effects to salmon and steelhead populations outside the operation of the dams. The Preferred Alternative includes biological, operational and structural measures and approaches for mitigation. Research continues to evaluate the magnitude of these effects. For more information, see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative would provide a substantial contribution to recovery of salmon populations.
2620	1	N/A	N/A	Though experimental in nature, and not without risk to ESA listed species, NLI is encouraged to see that the underlying principles and model of constructive collaboration established through the 2018 Flexible Spill Agreement (the Agreement or Flexible Spill) have been carried forward in the PA. To the extent that the Flexible Spill operation (as the backbone of the PA) is finalized by the co-leads as part of this EIS process, we insist that the three objectives of the Agreement remain intact: provide additional fish benefits by increasing spill; manage power system costs and preserve hydro system flexibility; and retain operational feasibility. NLI remains concerned however, about the wide variability around the two bodies of fishery science considered in the Draft EIS (i.e. NOAAs Life Cycle Model and The Fish Passage Centers Comparative Survival Study model). Most concerning, is that the extended operation at 125% Total Dissolved Gas (TDG) called for in the Flexible Spill Agreement (and the basis for the PA) is an unprecedented action at these federal projects. We appreciate that the co-lead agencies understand the potential controversy around the different assumptions made by each of the fish models, particularly when it comes to assessing the biological risks versus benefits of operations like the PA that incorporate increased and un-tested levels of spill. To address this issue, we would like to see strong fishery monitoring and adaptive management solutions put in place as described below. Support for Robust Fishery Monitoring and Adaptive Management. Throughout implementation of Flexible Spill, and as further adopted in this EIS, NLI urges the co-lead agencies to keep a close eye on the PAs untested operational approach, particularly spill to 125% TDG. Specifically, to continue to analyze the impacts of the proposed action on ESA listed salmon species. This includes the development of a robust monitoring approach and public platform for providing transparent feedback. We also encourage the co-leads to develop and improve upon an adaptive management framework to ensure that their actions do not jeopardize the continued existence of any listed species (as directed by Section 7 of the ESA).	As required by NEPAs implementing regulations, the co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used both primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the biological models and to will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored, as will the effects to generating resources around the basin. The Monitoring and Adaptive Management Plan, including the Adaptive Implementation Plan for the flexible spill operations, is included in Appendix R.
2620	2	N/A	N/A	NLI recommends that further analysis is needed to sufficiently quantify the potential socio-economic costs of a blackouts associated with MOs 3 and 4. Please see PNGCs comments for further thoughts on this point.	Substantial costs would likely result should blackouts occur. The EIS methodology includes the full incremental replacement resource cost necessary to return the region to a level where the likelihood of blackouts is equal among all the alternatives, such that comparisons can be made among the alternatives on an equal basis. The EIS assumes for each multiple objective alternative (MO) that sufficient resources are acquired to reduce the risk of blackouts to the level of risk that existed prior to implementation of each MO. Once replacement resources have been acquired, the risk of a blackout for each MO is effectively the same as the No Action Alternative. If the EIS had then also added to each MO the additional cost of a blackout, then the MOs would have double-counted the impact of blackout risk (i.e. the MOs would have included the cost of avoiding blackouts and the costs of blackouts). The Preferred Alternative includes an adaptive management plan that involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. Please see Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
2631	1	epaleck@gmail.com	N/A	The DEIS concluded that breaching the Snake River dams would have long-term, major, adverse effects on power costs and rates, and the rate pressure could be up to 50% on wholesale power rates. This is clearly incompatible with why electric cooperatives were formed 75 years ago and with our cooperatives mission which it is already difficult to fulfill. The DEIS concludes the dam breaching alternative would more than double the regions risk of power shortages. In an area already plagued by tall trees with only a 10 right of way on each side, reliability in adverse weather can frequently be an issue. Why increasing the duration and frequency of those outages would be desirable to support migrating juvenile salmon that already have a 96% survivability rate over dams is beyond me. Especially since our members are among those who have paid for these fish passage systems.	The comments that breaching the four lower Snake River dams would (a) increase the frequency of power shortages unless replacement resources were built, and (b) would result in increased costs in the region, are both consistent with EIS findings. The EIS also discusses the fact that Bonneville customers, such as cooperatives mentioned by the commenter, may be more directly affected by rate pressures than other regional utilities that do not purchase power directly from Bonneville.
2647	1	combopipey@gmail.com	N/A	S.E.corner of Washington, as well as S. Idaho,NE Oregon have both benefited from dams in many ways. Drought control, power, irrigation, farming, fish/wildlife habitat, power supply, financial stability(even sold to Southern Oregon and California) Many rural areas, from Idaho, Oregon, Washington all benefit from these, as suppliers for needed irrigation, water/flood control, for farming, jobs, even existance.. with out the water control(good and bad) these smaller communities would become non existent, or ghost towns in some areas, as well as impact larger towns, counties, cities, including larger cities such as Portland & surrounding, Seattle & surrounding, and more. Not only by financial impact, but livelihood, power, recreation, sustainability as	The EIS analyses the impacts to the region created from the operations, configuration, and maintenance of the 14 Federal projects. This includes an analysis of water management in light of drought, a scenario investigated across all resources; operations during low, high, and average water years (Section 3.2), power generation and transmission (Section 3.7), water supply (Section 3.12) and maintaining flood risk levels (Section 3.9). Affects to jobs and the economy are addressed through discussions on Navigation and Transportation (Section 3.10) and Water Supply (Section 3.12). Potential economic impacts are evaluated for social welfare effects (national economic effect), regional economic effects, and other social effects. Effects to livelihoods are captured to the extent possible in the regional economic effects and other social effects sections that follow. Please see Section 3.12 and Appendix N for additional information.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				well as stabilization. Also may want to consider, and include, physical and geological stability, flood control, and useability (besides just the power created) of areas, due to water control and dams. I am not just referring to recreation nor occupational, but also the actual land, land management, land useage, and availability of these, due to water control and usability created by dams.	Land management is part of the maintenance of these Federal projects. Some land transfers would be anticipated with implementation of alternative MO3, if selected, as the Federal projects are closed out after construction and mitigation is completed. However, the changes of land usage outside of the Federal project was not anticipated to change due to any of the alternatives, except for MO3, which would require additional study and NEPA analysis for implementation if selected. The Preferred Alternative is not anticipated to impact any land usage.
2647	2	combopipey@gmail.com	N/A	can you please show, or explain with research documentation, a break down of 1 cost 2 volume 3 access/egress 4 fuel consumption 5 maintenance/expense, of equal transport, by: waterways, highways, trains, planes, pipelines and trucks? By the way, do us all a favor, and print, display, and report these finding publicly....	The costs of system operations are addressed under Section 3.19 with additional details describing methodology provided in Appendix Q. The navigation and transportation effects are discussed in Section 3.10 with additional details and source information provided in Appendix L.
2648	1	N/A	N/A	While the Preferred Alternative is good, there is a flaw in the EIS process that doesn't look broadly enough at the issues. In this case, replacing the hydro-power generation with CO2-generating power will hasten global warming. Although it can be argued that the power will be replaced by solar and wind, these aren't baseload power sources - thus requiring either enormous national investment in grid distribution or building peaking power plants. In any society, resources are not limitless, so we must consider the overall energy system to make optimal decisions. If, as is likely, we end up with peaking power plants, it will hurt in two ways: (1) these funds then aren't available to reduce CO2 emissions in other ways, and (2) the additional CO2 threatens not only these identified species of fish, but literally millions more. The health of these river ecosystems is obviously important, but our time to reduce global warming is short. Until we can start bringing down global CO2 emissions, reducing this non-CO2 emitting power is a nicety that comes at a very real, but unmeasured and unconsidered, cost. I would therefore suggest additional consideration be given to MO2.	The EIS considers the effects of each of the alternatives on greenhouse gas emissions, finding that all alternatives would result in increased emissions, even if all replacement resources are renewables, with the exception of MO2; and MO1 if replacement resources are all renewables. Section 3.8 provides the emissions effects of the alternatives both in terms of increased carbon emissions and the social cost of carbon (i.e., the economic value of climate-related damages associated with the emissions). However, while MO2 best meets the objective of minimizing carbon emissions, it does not meet or only partially meets several other objectives. The Preferred Alternative identified in the Draft EIS does meet the objectives for: ESA-listed juvenile and adult anadromous salmonids, resident fish, lamprey, hydropower generation, water management and water supply.
2685	1	brett.costley@gmail.com	N/A	The DEIS concluded that breaching the Snake River dams would have long-term, major, adverse effects on power costs and rates, and the rate pressure could be up to 50% on wholesale power rates. This is clearly incompatible with why electric cooperatives were formed 75 years ago and with our cooperatives mission which it is already difficult to fulfill. The DEIS concludes the dam breaching alternative would more than double the regions risk of power shortages. In an area already plagued by tall trees with only a 10 right of way on each side, reliability in adverse weather can frequently be an issue. Migrating juvenile salmon already have a 96% survivability rate over dams. Increasing outages to improve on that high number strikes me as a tradeoff with a very low reward and a very high price. Thank you for your unbiased overview of this situation. Sincerely yours, Brett Costley Board President West Oregon Cooperative	The comments that breaching the four lower Snake River dams would (a) increase the frequency of power shortages, and (b) result in increased costs in the region, are both consistent with EIS finding as described in Section 3.7. The EIS also discusses that Bonneville customers, such as cooperatives mentioned by the commenter, may have larger increases in rate pressures than other regional utilities that do not purchase power directly from Bonneville.
2689	2	guilrl@yahoo.com	N/A	I read the EIS Executive Summary on the subject draft EIS, but could not access the entire document online via the link provided by Rep. Dan Newhouse, reference as available via Capital Press which requires a subscription. I did read the Executive Summary which I had a very hard time reading. Here are some of my comments on the Executive Summary: 1.) Each alternative, including the no action alternative should summarily address what it is upfront in bold, and what defined objectives it meets or does not without too much wording and then go into a little detail as to why, or why not. A.) The way it is written is very ackward for an Executive summary for a reader that wants to get the highlights only. B.) This summary is very confusing as written. C.) When I tried to download the entire document to read my device locked up and I had trouble unfreezing it. D.) I have no idea which dams were considered for breaching or not, or which dams are required for shipping or irrigation. E.) Was there any consideration for clean energy storage alternatives without adding having to consider more polluting energy alternatives to compensate for dam breaching cases. F.) Which dams preclude salmon migration the most? 2.) I was very confused as to exactly what is the preferred alternative as defined in the Executive Summary. I wanted it to be clearly defined as MO 1, 2, 3, or 4, and the Executive Summary did not blatantly say what it is. MO1, MO2, MO3, or MO4, and why? 3.) Did the EIS study include any assessment regarding the structural condition of any or all of the dams, or the remaining life of any of these dams, and the environmental risks posed by any dams that may require them to be replaced? I hope to hear back from you regarding addressing a reply to each of these questions I that have at this time. If possible please also provide me with a better link to the entire draft EIS. Sincerely looking forward to your replies to these questions. Thank you.	We responded on March 31, 2020 to help you identify the link to access the full document from the official site. 1) The Executive Summary as noted would not contain all the analysis but would introduce what would be covered in the main report. In one of the alternatives being considered, MO3, the agencies analyzed the effects of removing the earthern portion of the four Federal dams on the lower Snake River. These are: Ice Harbor, Lower Granite, Lower Monumental and Little Goose. All alternatives are described in Chapter 2. All four of those dams, plus the four dams on the lower Columbia, are required for shipping via the navigation channel. The lower Snake River dams also provide water elevations for regional water pumps. These analyses are in the Navigation and Water Supply sections of Chapter 3. Energy demands and considerations for clean energy to replace those demands are in the Power and Transmission section of Chapter 3. All eight dams on the lower Columbia and lower Snake River dams have significant infrastructure, including fish ladders, spillway weirs, and updated fish passage turbines that allow both upstream and downstream fish passage and do not preclude salmon passage. Specific fish, such as Pacific lamprey, require different passage measures, which are proposed in the alternatives of this study. 2) Chapter 7 specifically describes the Preferred Alternative. 3) Yes, the EIS included the condition of the infrastructure and maintenance costs. There is not any replacement of dams anticipated.
2690	1	spauley4@gmail.com	N/A	Please see the 2002 Rand Report on breaching.	The EIS acknowledges previous analyses of breaching the four lower Snake River dams, such as the 2002 RAND analysis referenced in this comment. However, the EIS relies on current information to evaluate the tradeoffs associated with breaching the four lower Snake River dams included as part of Multiple Objective Alternative 3. This includes applying current models and data rather than relying on findings from studies conducted nearly 20 years ago. Section 3.7 of the draft EIS describes potential uses of zero-carbon resources (alternative resources) to meet the energy demands in the Northwest if hydropower generation is reduced.
2735	1	jld@pocketinet.com	N/A	I am disappointed that the EIS does not emphasize the importance of barging smolts past the dams, as it has been proven to be the most productive way to get smolts down the river and enhance their return. Please give this option, as opposed to more spill, more emphasis in your final report.	The co-lead agencies used current high quality information and the best available scientific information on this subject. Their analyses of the alternatives includes analysis of transportation, or barging, of juvenile salmonids past the dams. Varying levels of transportation were included in all MOs with the exception of MO3 (dam breach). MO2 considered much higher levels of transportation that are currently implemented under the NAA. Transportation effects were also analyzed in the Preferred Alternative.
2752	1	abailey@otecc.com	N/A	One additional reason given by the politicians for dam breaching is it would provide more feed for the Southern Resident Killer Whales (SRKWs). Based on a study performed by NOAA - Northwest Fisheries Science Center this is not the case. They have identified that SRKWs primarily forage on chinook salmon that originate from the rivers in the northern Puget Sound, Georgia Strait and the Strait of San Juan de Fuca. Two studies indicate that these chinook populations are being intercepted by sport and commercial fisherman off the coast of B.C. and Alaska. Using genetic analysis, researchers in the U.S. and Canada found that 80 to 90% of chinook consumed by the SRKW originated from the Fraser River. An estimated 6 to 14% likely originated from tributaries within the Puget Sound. These studies and the related information should be considered before any detrimental decisions are made that effect the FCRPS.	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies utilized current high quality information and data to analyze the impacts of operations, maintenance, and configuration of the CRS projects. Many of the effects listed in this comment are beyond the scope of this EIS.
2752	2	abailey@otecc.com	N/A	There are several areas that we believe need to be further vetted: 1) Predation of salmon smolts by the cormorants (and other birds), and 2) Predation of returning adults by California Sea Lions and seals are residing in the Columbia River system in record numbers. We appreciate the ability to use lethal force on problem sea lions and seals, but the growth in these populations is not even being touched by this effort.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
2752	3	abailey@otecc.com	N/A	The Federal government is requiring a new cost allocation study for the dams in the FCRPS. This is a problem that has increased over time. All costs being considered in this document need to be allocated to the various users of the FCRPS dams.	The report on the House Energy and Water Development Committees Appropriations Bill for Fiscal Year 2020 includes language that directed the Corps, Reclamation, and Bonneville to jointly develop an outline for conducting cost allocation studies for relevant projects within the FCRPS. As stated in the Bill, the outline must include a prioritized list of projects for which cost allocation studies should be conducted and the scope necessary to perform the study. Once the outline is complete, the co-lead agencies are required to brief the Committee with the results. Work is underway on this outline, but whether any new cost allocation studies would be developed as a result of this process is speculative. Thus, the cost analysis provided in the EIS focuses on the current cost allocations. The cost allocations used in this EIS were developed based on methodologies adopted by Corps and Reclamation and reflected in their policies. Although each methodology has a different approach, the fundamental goal of any cost allocation is to allocate a share of the projects costs (capital and O&M) to each of its authorized purposes (e.g. flood control, navigation, power, irrigation). Fish mitigation costs are assigned to each authorized purpose based on each purposes overall share of project costs, as determined by the cost allocation. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Although Congress authorized Bonneville to fund the power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992. (Energy Policy Act of 1992, Pub. L. No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)), in some situations, including the Columbia River Fish Mitigation program, Bonneville does not directly pay for the capital costs of fish mitigation structures; instead it reimburses the U.S. Treasury for the power share of appropriations used to construct the structure.
2753	1	kenboire@aol.com	N/A	Published NEPA guidance is clear. The identification and evaluation of alternative ways of meeting the purpose and need of the proposed action is the heart of the NEPA analysis. The lead agency or agencies must, objectively evaluate all reasonable alternatives, and for alternatives which were eliminated from detailed study, briefly discuss the reasons for their having been eliminated. Reasonable alternatives are those that substantially meet the agencys purpose and need. Reasonable alternatives include those that are practical or feasible from the technical and economic standpoint and using common sense, rather than simply desirable from the standpoint of the applicant. Agencies are obligated to evaluate all reasonable alternatives or a range of reasonable alternatives in enough detail so that a reader can compare and contrast the environmental effects of the various alternatives. After reading the report one curiosity remains unaddressed. What would be the economic effect and change in fish numbers that would result from curtailing all sport and commercial fishing for pacific salmon in the ocean, estuary and river. In the report, life cycle concerns are analyzed via a menu of models. Smolt to adult survival including ocean years and latent mortality were considered as was removal of hatcheries but removal of all harvest seems to be absent. Harvest effects are estimated by models using inputs drawn from historical data but there are no zero harvest years in the file. The evaluation of a zero-harvest measure or alternative in any form seems to be totally absent from the report. The report addresses changes in yearly harvest success, and this is modeled in the EIS, but there is no zero-harvest option to mix in and no zero-harvest year to stand alone. Seems logical to the lay person that foregoing all forms of harvest could reasonably contribute something to recovery especially since harvest appears to constitute a taking.	Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the 2018 EIS from NOAA and reflect current harvest management guidelines. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and Tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and Tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				Maybe the present EIS alternatives would become different or might be down scaled if their performance were to be measured as increments added after implementation of harvest restrictions?	
2762	1	Jim Retzer	City of Colfax	As you prepare your final EIS, we would like to propose further study of the impacts of dam breaching on the agriculture producers bordering the lower Snake River.	Absent more specific parameters for requested further study, please see Section 3.10.3.5 for three social welfare scenario analyses of the effects of dam breach on grain transportation costs at a constant rate, and rate increases of 25 and 50 percent. The regional economic effects to agricultural operations were also analyzed for two hypothetical farmers, one near Colfax, Washington, and the other near Grangeville, Idaho. The respective proximity of each illustrates how the effects of dam breach would differ for specific geographic locations and the potential resulting shipping choices and costs per scenario discussed.
2762	2	Jim Retzer	City of Colfax	Between 50 and 60 million tons of cargo are transported each year on barges that can navigate the lower Snake River. These goods move faster and more cost efficiently by river than train or truck - and with far less carbon emissions. Eliminating this asset would irreparably hurt our wheat farmers. More than 1,100 farms risk bankruptcy if barging is lost, according to a study commissioned by the Pacific Northwest Waterways Association . The federal government would need to increase farm subsidies by $38.8 million to simply maintain current income levels. Inclusion of such figures in the final -EIS would help to portray the personal impacts to farmers for future discussions.	Section 3.10 of the EIS recognizes that access to barge transportation is the most cost effective means of accessing export markets for the majority of grain producers in the Pacific Northwest currently and removing that option would increase transportation costs for grain producers. The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. The EIS finds that under MO3, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted. The EIS recognizes that there is no guarantee wheat grown in the Northwest would be competitive now or in the future because there are many factors that influence international commodity markets (e.g., trade agreements, the U.S. dollar, global supply, etc.). However, the analysis finds that the cost to transport wheat to market would continue to be lower than costs paid by other wheat growers in the United States (e.g., the Dakotas and Midwest). Favorable conditions for Northwest wheat growers that help them stay competitive are: (1) the natural environment of the Palouse region (weather, soils) is ideal for growing this type of wheat, which leads to some of the highest yields per acre in the world, and (2) proximity of Northwest export ports.
2775	1	kate@columbiariverkeeper.org	N/A	Water temperature is a major problem for salmon and steelhead Between 1960 and 2015, water temperature in the Columbia and Snake River have increased by an average of 1.4F. (https://www.epa.gov/climate-indicators/snake-river). Salmon are sensitive to water temperature at many stages of their lives. Warmer water can negatively affect fish, making it more difficult for them to swim upstream, and making fish more susceptible to disease. (https://www.epa.gov/climate-indicators/snake-river) In the Lower Snake River, temperatures in the reservoirs exceed 68F for weeks or months at a time during the summer when many salmon migrate to or from the ocean. Temperatures above 68 degrees are very harmful to salmon. Salmon populations in the Snake River Basin are increasingly threatened by warmer rivers, including significant warming from the reservoirs behind the four dams on the Lower Snake River. The DEIS analysis is insufficient on several levels. In the analysis of climate change. The EIS should model water temperatures in the Columbia and Snake rivers under the climate conditions we expect to see in 20 to 50 years. In addressing the challenges that salmon face in the Columbia River and estuary. Existing dams and worsening climate change are making the lower Columbia River and estuary too hot for fish. The DEIS does not explain this or provide any solutions. The DEIS implies that Lower Snake River dam removal would not significantly change water temperatures or improve conditions for salmon. This is not true. Summer and fall water temperature conditions in the Lower Snake would be significantly better for salmon and steelhead with the dams gone.	The Draft EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the effects of alternative approaches to operations, maintenance, and configuration of the CRS projects on Snake River stocks, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Regarding climate change, the climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at this time. Therefore, it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (see Section 4.2.3). Regarding lower Snake River water temperatures, the co-lead agencies' analysis of MO3, the alternative that includes the measure to breach the lower Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than the conditions in the No Action Alternative. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during high air temperature events.
2779	1	afergu@gmail.com	N/A	First off, I am unhappy about the inadequate and confusing public comment teleconferences. I waited for over 2 hours despite pressing 1 and 0 immediately at the very beginning to be placed in the queue to give comment before finally giving up. I wish the CRSO would've extended the public comment period in order to hold in-person meetings or otherwise increased opportunity for public comment due to the impacts of the COVID-19 epidemic.	We are sorry you had technical difficulties. We hope you were able to provided comments into the online form or through mail. The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EOS website notified the public on April 9 that they should plan to submit comments by the close of the comment period.
2779	2	afergu@gmail.com	N/A	The DEIS overstates the cost of replacing power from the Snake River dams with clean energy, and suggests replacing their power with fossil fuels.	The EIS describes the replacement resources that would be needed to maintain regional reliability at the No Action Alternative levels based on a range of potential replacement resources, including one that is based on renewable resources and another that is based on natural gas resources, which are generally the least cost means to maintain reliability (see Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS). The EIS uses the best available resource cost information from the Northwest Power and Conservation Council to estimate the potential range in costs of these replacement resources. The EIS does not suggest fossil fuels should be used to replace the power; the purpose of providing the range of replacement resource options is to estimate a reasonable range in potential costs. The basis for developing both of these portfolios may be found in Section 3.7.3.1, Methodology, and Section 3.7.3.5, Potential Replacement Resources and Associated Costs for MO3 in the draft EIS, specifically. The EIS uses the best available resource cost information from the Northwest Power and Conservation Councils 7th Power Plan and Mid-Term update to estimate the potential range in costs of these replacement resources, with the exception of batteries which used newer sources, namely, 2018 and 2019 IRPs from Northwestern Energy and Puget Sound Energy. To further address concerns about potential reductions in resource costs publicly released draft information, such as updated prices for solar and battery storage, from development of the 8th Power Plan is included as rate sensitivities in the Final EIS. The Final EIS will include the de-escalating cost curves prepared by the National Renewable Energy Laboratory (NREL) that will be used by the Council in the 8th Power Plan.
2780	1	boleneus@gmail.com	N/A	Removing the Snake River dams creates a huge electricity shortage. All should be concerned. HOPE for wind renewable electricity is misplaced because wind turbines repeatedly show no ability to perform. The wind turbine record shows it a less than part-time supply and so the fickle wind turbines must rely on dams that some wish be removed. The four Snake R. dams provide 3,033 MWs of electric to serve 1,022,000 homes full-time. Here are reasons that electricity will be inadequate in the future: a- Washington created a new electricity law in 2019 which denies use of coal and natural gas to generate electricity by 2045, thus mandates wind turbines, a mistake because natural gas is very abundant. b-By 2045 35% more customers demand electric as population grows 1.5% per year so I write here for pre-school age family members that cannot comment. c-The new law relies on wind and solar to make up the deficit, but this projection and history shows they will fail. The unreliable supply, and unaffordable high cost to 45 cents/kwh of wind and solar in Ontario, Australia and Europe (Spain, Germany, Denmark) PROVES renewables cannot fulfill the false hope that legislature failed to verify. That cost is not the cost for electricity but cost is due to supercharges added needed to support carbon-free renewable wind or solar, for example, in Ontario and Germany. To see the shortage, look at any two week winter period, but I used November 2019 to know what supply is transmitted by BPA and project this to November 2045. d- Now remove electricity from coal, natural gas, and the 4 Snake River dams, and double wind capacity to 8740 MWs5,800 turbines–and solar to 82 MW. The result shows that the shortage, or deficit for only two weeks is 154,820 MW, enough to supply 259,765 homes is not available. The message is clear that 700,000 customers must go without electricity. Who are 700,000 to volunteer for NO lights, NO cell phones/computers, NO cooking, NO heating, NO refrigeration, NO electric cars? BATTERIES cannot fill this need. This simple projection shows how utterly absurd is this proposal. A wind turbine fleet rated at 35% of the hydroelectric capacity is unable to replace the 11% of the hydroelectric that you propose to eliminate. e-The main reason that electric is not there and voiced by a BPA employee is this: Our wind turbine electric generation record shows wind only provides 4% of its capacity during the 5-6 months, Oct to mid-March because wind turbines are not producing on average 15 days each month because the wind is not blowing. The up-and-down yo-yo generating record of wind is chaos and the 2019 electric law is a disaster in the making as would be loss of the 4 Snake River dams in a time of need.It clearly shows that even 1,000,000 MW of wind will produce no electricity if the wind is uncooperative. All must realize that the intermittent nature of wind cannot promise electricity. I have prepared a poster to support this comment but it is larger than 2MB I am not sending so please request if you wish to see it.	The comment correctly identifies that wind and solar energy have lower capacity factors than natural gas and coal resources, and that hydropower is used to maintain reliability and avoid outages when these resources are not able to generate sufficient power to meet demand. The Draft EIS evaluates the potential for renewable replacement resources to maintain system reliability given a reduction in hydropower generation. The analyses of the alternatives do take into account that, unlike hydropower and fossil fuel sources, wind is an intermittent resource (i.e., cannot always ramp up generation to meet demand) in identifying the amount of added capacity that would be required. The EIS also finds, consistent with this comment, that increasing retirement of coal power plants would adversely affect regional power reliability. The EIS does not answer the question of whether renewable resources will be able to replace all fossil fuel resources in Washington State as the focus of the analysis is specifically on the management of the Columbia River System projects. The EIS identifies the amount of renewable replacement resources that would be needed to maintain reliability under Multiple Objective Alternative 3 (which includes breaching the four lower Snake River dams) at the No Action Alternative levels. Even with these renewable resources, as described in the EIS, existing fossil-fuel plants would likely run more. The EIS also discusses the cost of using only renewable resources as replacement resources, which would come at a more substantial cost than if fossil fuel resources are used. See Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the draft EIS.
2780	2	boleneus@gmail.com	N/A	The Snake River permits 360 miles of river shipping commerce of 9 million tonnes annually up and down the Snake River to Lewiston valued at $4 billion each year. Up to 40,000 jobs are at stake. The loss of shipping on the Snake would each year add 345,000 trucks to highways to carry freight that now uses the Snake River more cheaply than more expensive highway travel. Trucks transporting these products would use 370% more fuel than barge shipping to transport the same freight.	Section 3.10 of the EIS evaluates the increased costs of transportation as well as the increased number of truck trips that would be required if the four Snake River dams were breached under MO3. The EIS recognizes that transportation cost increases could decrease profitability of farming. The number of truck trips could substantially increase, ranging from an additional 14,000 to 79,000 truck trips per year, which would increase air pollutant and greenhouse gas emissions in the region and add to traffic and congestion in the region. The EIS describes, in Section 3.10, that deep draft ports on the Columbia River are important to the regional economy and support approximately 40,000 jobs. The EIS also recognizes these ports receive some cargo from the shallow-draft areas of the Columbia River Navigation System. However, the EIS also recognizes that most of the cargo that goes through the deep-draft ports is shipped directly via rail or truck from inland areas and exported. The total volume of cargo passing through the deepwater ports is not anticipated to be affected under MO3, which includes the dam breach measure.
2784	1	melibeekoch@gmail.com	N/A	The removal of the Elwha dam is a good example of an action that has had a positive impact on the natural environment leading to the return of salmon and steelhead for the first time in one hundred years.	The effects of removal of the Elwha Dam and the effects of breaching the lower Snake River dams are not comparable. Elwha Dam had a nameplate capacity of just under 15 megawatts. Its annual power production pales in comparison to the 1,100 aMW provided by the lower Snake River dams. Also, Elwha Dam did not have fish passage. The four Snake River dams do. Removal of the Elwha dam allowed the Elwha River to flow freely. Even if the four Snake River dams were removed, the Snake River would still have regulated flows due to the dams located upstream.
2785	1	N/A	N/A	Please extend comment period as many public hearings have been canceled and delayed due to the current pandemic.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received to date and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9 that they should plan to submit comments by the close of the comment period.
2785	2	N/A	N/A	Thus far, the EIS's and Recovery Plans prioritize economics over conservation. Previous EIS by Army Corp of Engineers has shown breaching the 4 lower Snake River dams is the best alternative for salmon recovery, yet was rejected, prioritizing economic impacts to agriculture, transport, and energy production. These industries are subsidized and can continue to be subsidized transitioning to sustainable industries.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. In this EIS, the Preferred Alternative meets the eight objectives of the EIS, including two objectives to improve passage and survival for ESA listed fish. Additionally, it meets the EIS purpose and need and minimizes adverse impacts to the human and natural environment.
2785	3	N/A	N/A	Declining, endangered Southern Resident killer whales are dependent on Columbia Basin- Snake River salmon. As NOAA's Recovery Plan states: "the single greatest change in food availability for SRKW since the late 1800s has been the decline of salmon in the Columbia River Basin." NOAA has included the coastal Columbia River Basin as part of SRKW Critical Habitat, and federal agencies and operations will have to comply. I also support MO34-Spillovers. With the US 9th Circuit Court mandated spillover in 2013, there was a SRKW 'baby boom' of 9 calves in 2014-2015. Best available science has shown availability of enough salmon directly correlates with successful births.	The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies utilized current high quality information to analyze the effects of operation, maintenance, and configuration of the CRS projects. Without a reference that demonstrates that the increase in calves was directly related to increase spill, the co-lead agencies are not able to assess the credibility of this claim or whether it is the best available science. To the extent that "spillover" means higher spill operations for juvenile fish, the Preferred Alternative does include spill levels that are higher than would have been undertaken in 2013, which is expected to have benefits for juvenile survival.
2791	1	tim@timpalmer.org	N/A	I'm the author of 28 books about resource issues, and my comments here are informed by three books I have written: Endangered Rivers and the Conservation Movement; The Snake River: Window to the West; and The Columbia: Sustaining a Modern Resource, and also by continuing research and reports from many sources. Virtually all the research I did for these books and for work after them indicated that benefits of the four Snake River dams are grossly exceeded by the costs in public subsidies to the barging, hydropower, and irrigation industries and by the costs of allowing these dams to drive our salmon and steelhead toward extinction. Any argument that dam removal does not provide for "certainty" of salmon recovery is logically flawed because that "proof" will only be accepted as fact after it has occurred. Except for reports from entities paying for work that supports keeping the dams intact, and work by agencies deeply invested in sustaining the status quo, the evidence of both biologists and economists say that we need to remove these dams to sustain the salmon and to make our public agencies solvent. The four dams provide less than 4 percent of our regional powerpower that is available mostly when it is in surplus, and it is easily replaced by alternative sources without the problems that the dams are causing. Unlike what was delivered in the past five plans, I urge you to revise this DEIS to provide a fair and accurate report this time. I urge you to consider the full costs of these dams and a full accounting of the benefits of restoring our salmon and building a sustainable economy that is not predicated on the extinction of our native fish and other valuable natural resources.	The CRSO EIS documents the assessment of benefits and impacts of changes to the operations of the 14 Federal projects of the Columbia River System. Using a multi-disciplinary approach and with the coordination and consideration of our cooperating agencies and Tribes, as well as public stakeholder input, and by using current, high quality information, the co-lead agencies developed the Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the FCRPS from which Bonneville markets power. As described in Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are among the most valuable projects in the Federal Columbia River Power System (FCRPS). These dams provide over 1,000 MW of carbon-free energy and up to 2,000 MW of sustained peaking capacity at certain times of the year. The regional power system is surplus during certain times of the year and in certain water conditions. However, without the generation from the four lower Snake River dams, the region would face power shortages (potentially blackouts) in roughly one out of seven years.
2792	1	annvil@earthlink.net	Kalmiopsis Audubon Society	The Agencies preferred alternative is similar to the approach that has already failed and already been rejected 5 times by a federal court over the last 25 years. We believe it also violates the Endangered Species Act by neglecting to take seriously enough the risk of extinction to salmon, steelhead, and orcasand fails to give sufficient attention to the impacts of climate change.	The co-lead agencies disagree the Preferred Alternative is a similar approach to operations prior to the CRSO EIS. The Preferred Alternative carries forward certain mitigation measures that are known to provide benefits to ESA-listed species from the No Action Alternative. These actions by the co-lead agencies have resulted in a large percentage of fish being able to pass both upstream and downstream of the lower Snake River and lower Columbia River projects. Please see Section 3.5.2.3 Anadromous Fish for additional discussion. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations. Please see Section 7.6.3 Preferred Alternative Operational Measures for additional discussion. In addition, a large number of structural changes are included to benefit salmonid species and Pacific lamprey. Please see Section 7.6.2 Preferred Alternative Structural Measures for additional discussion. Based on the fish analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies' obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-leads to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. See also Chapter 8, Compliance with Environmental Laws, Regulations and Executive Orders. The EIS analysis of the Preferred Alternative determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. Regarding climate change, through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for the Preferred Alternative. With the uncertainty associated with climate change, it is important that we establish methods for adapting and increasing flexibility on the system. There are measures in the Preferred Alternative that are adaptive to emerging changes in climate and ensure there is flexibility to respond to future changes. One example of this is the habitat restoration program that counters increased stream temperature with deeper pools and more shaded areas. See Chapters 4 and 7 for additional information on climate change.
2792	2	annvil@earthlink.net	Kalmiopsis Audubon Society	Rather than kick the can down the road, wasting more time, and millions of taxpayer dollars more on continuing legal conflicts, I urge the agencies to revise the EIS to focus on the three things that will truly have a chance of working: Removal of the four obsolete Snake River Dams, Increased flows over Columbia River Dams And habitat restoration In addition, please remove killing native predator species from this plan.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Additionally, the co-lead agencies evaluated many different flow and spill levels and as well as seasonal patterns for when flows are enhanced or reduced. The Preferred Alternative represents an operation that provides a balanced approach between spring and summer flow and spill levels to benefit salmon and steelhead, while also providing benefits to resident fish in the upper portion of the Columbia River Basin. Although the Preferred Alternative does not include breaching of the lower Snake River dams, it calls for actions that are different from those that have been implemented in the past. One major change that the Preferred Alternative represents is a new spill operation during spring juvenile fish passage, which would test an innovative approach to balancing fish benefits and energy goals by spilling more water in the spring for juvenile fish passage. The intent is to increase spill when the projected value of power is relatively low, pass higher proportions of fish through the spillway, and spill less water for limited durations when the projected value of power is relatively higher (i.e., during peak power demand). In terms of habitat restoration, the co-lead agencies have supported and will continue to support habitat restoration throughout the Columbia River Basin. See Chapter 7 for additional information on tributary and estuary habitat actions being carried forward into the Preferred Alternative. The co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including implementation and adaptive management of actions for the purpose of reducing predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The co-lead agencies recognize the value of developing common metrics, identifying measures, and implementation of measures that will aid in the reduction of predation impacts and increase survival of Columbia River salmon and other native fish populations. However, the co-lead agencies are limited to implementing measures that are within the authorities of the agencies. The Preferred Alternative includes predation mitigation measures, including maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates, all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia River. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary. Chapter 7, and Appendix R, include mitigation measures associated with the Preferred Alternative and describe ongoing habitat restoration programs of the co-lead agencies. Predation management will be an ongoing effort, not only by the co-lead agencies, but by other entities as well. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from Columbia River System operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Increasing flows as a potential measure was evaluated in the EIS. In particular, the McNary flow measure in MO4 demonstrated significant adverse effects to upper Columbia basin fish and wildlife, as well as cultural resources. As described in Chapters 5 and 7, the agencies are proposing to continue habitat restoration actions described both under the No Action Alternative as well as new mitigation for the Preferred Alternative. The commenter was also concerned with killing of native predator species. It is unclear which native species the concern was indicating; however, certain native predators adversely affect survival of listed fish species and taking actions to keep a balance is a tool in our strategy. These decisions are not made lightly and are coordinated with resource agencies such as NMFS and USFWS.
2794	1	N/A	N/A	The latest US/Canada Salmon treaty raised the allowed salmon catch to rise from 94 million to 134 million. That has an impact on the reduced salmon in the Columbia River.	We agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm Harvest certainly has an impact on salmon and steelhead populations. The three co-lead agencies do not manage fish stocks, and do not have the authority to do so. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and tribal fishery managers based on a variety of environmental, biological, economic, and social factors. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and.
2794	2	N/A	N/A	Try to count the number of sea lions living in the Columbia. Get an estimate of their Salmon catch per day when Salmon are in the Columbia River. I think this number will over exceed the Dam losses by the millions!	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					generally continue to ensure compliance with the ESA. Regarding pinniped predation, sea lion management decisions at Bonneville Dam rely on input from the Sea Lion Management Working Group. This Working Group is a collaborative effort with NOAA, USFWS, various Tribes, and the co-lead agencies. The co-lead agencies works to minimize the effects of sea lions on salmon by implementing Best Management Practices specified in the NOAA Biological Opinion and by implementing recommendations developed by the Working Group. The co-lead agencies will continue to use this process to minimize the effects of sea lions on salmon within their authorities. As part of these efforts, the co-lead agencies monitor and count sea lions in the vicinity of the Bonneville Dam tailrace. The EIS discusses the Working Group and sea lion management in Section 3.5, 3.6 and Chapters 5 and 7. Other entities in the region (e.g., NMFS, the states of Oregon and Washington, and local Tribal governments) have authorities and obligations to mitigate the impacts from pinnipeds, and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
2800	1	riverrats04@gmail.com	N/A	Please change the selected alternative for the DEIS and/or add breaching (bypassing) of the four Snake River dams for a potential solution to save our endangered wild fish.	All four of the lower Snake River projects include both upstream and downstream fish passage. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
2802	1	N/A	N/A	To save the endangered Snake River salmon, Southern Resident orcas and ratepayers money, the federal agencies need to address the Columbia River System in a two-tiered process. Tier one is an emergency response action for the immediate drawdown and breach of Lower Granite and Little Goose dam, followed by the remaining two dams in subsequent years. Tier two is addressing system operations and further mitigation activities in the rest of the Columbia River Basin using the new EIS, assuming that the four lower Snake River dams.	The Draft EIS evaluated under Multiple Objective 3 (MO3) removal of the earthen embankment of the four lower Snake River dams (referenced as tier one in the comment) including operations (referenced as tier two in the comment) of the other ten Federal dams in the CRS and mitigation for effects to resources from implementing this alternative. If MO3 were selected, the Corps could use this EIS as a basis for seeking congressional authority to breach the four lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. The ESA does not require the co-lead agencies to take affirmative actions to support recovery of ESA-listed species. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The EIS analysis in Section 3.6 (Vegetation, Wetlands, Wildlife and Floodplains) The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). Additional details on the most crucial prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by USFWS. The Preferred Alternative carries forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.7 in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative.
2817	1	dick.Ledgerwood@gmail.com	N/A	The MO3 alternative involves a proposed breaching of the earthen portions of each dam to return the river to a stream bed flow, i.e., a drawdown. While breaching and drawdown was not part of the preferred alternative in the draft, such dramatic action is apparently supported by some in the region as a method to help restore endangered anadromous fish runs. While negative aspects of drawdown were discussed in the draft, I do not believe the full impacts associated with drawdown were adequately described. I believe that if such a management action were permitted the entire region would experience a catastrophic economic consequence and it is quite possible we would still lose the fish.	MO3 was not identified as the Preferred Alternative. Beneficial and adverse effects are discussed by resource area within Chapter 3, including effects associated with MO3 which includes the measure to breach the four lower Snake River dams. The EIS covers a broad array of resource areas covering the entire Northwest. The co-lead agencies intended to capture all significant changes to environmental resources and the human environment, but without more information from the commenter, cannot improve on what the commenter believes is missing in the analysis. There are benefits and costs associated with operating the four lower Snake River projects. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level; effects are monetized and quantified, where possible, and also described qualitatively. As is common in NEPA analyses, the beneficial and adverse effects of the alternatives are expressed as a variety of qualitative and quantitative environmental and economic metrics throughout the EIS to inform decision-making, including the effects of the alternatives on fish as detailed in Sections 3.5 and 7.7.4. That the effects of the alternatives on fish are not expressed as monetized economic values does not mean that they were not considered in the context of the analysis. The EIS does not employ a cost-benefit framework for decision-making consistent with NEPA (see 40 C.F.R. 1502.23). For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170 in the Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
2817	2	dick.Ledgerwood@gmail.com	N/A	MO3 does acknowledge that drawdown would shift major traffic to land transport and result in increased maintenance. I fear the impact of drawdown could totally disrupt land transport far beyond merely wear and tear on roadways and increased traffic. It is not practical to transport bulk cargo such as wheat by land and retain a competitive world market price, even if road and rail where enhanced and not compromised by drawdown. Further, any option to collect and transport juvenile salmonids by barge would likely be lost, particularly important in low flow drought years	The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted. The EIS recognizes that there is no guarantee wheat grown in the Northwest will be competitive now or in the future because there are many factors that influence international commodity markets (e.g., trade agreements, the U.S. dollar, global supply, etc.). However, the analysis finds that the cost to transport wheat to market would continue to be lower than costs paid by other wheat growers in the United States (e.g., the Dakotas and Midwest). Favorable conditions for Northwest wheat growers that help them stay competitive are: (1) the natural environment of the Palouse region (weather, soils) is ideal for growing this type of wheat, which leads to some of the highest yields per acre in the world, and (2) proximity of Northwest export ports. Environmental and human health effects associated with increased emissions to shipping goods by rail or truck (or both) are evaluated and described in the Section 3.8 Air Quality Section, and increased health and safety concerns due to increased truck traffic on roadways and potential for increased accidents are described in the Section 3.10.3.5 Navigation and Transportation other social effects. There would be no juvenile salmon and steelhead barge transport under MO3. There is the capability to transport from McNary; however, that is only included in Multiple Objective 2. It is not part of the No Action Alternative.
2817	3	dick.Ledgerwood@gmail.com	N/A	Drawdown, much like following the 1980 eruption of Mt St Helens, would likely push extreme sediment loads and resident fish populations downstream into McNary pool. Limnology studies in Lower Granite Reservoir in 1994-95 found sand and fines were more abundant than gravel in all shallow-water sample areas. Following drawdown sediment loads would likely be high for several years. Following the 1980 eruption of Mt St. Helens, resident fish populations (i.e., Pike Minnow) in the upper Columbia River estuary (Rkm 75) increased dramatically as they were crowded downstream to a more suitable environment. Similar downstream displacement of predators and sediment to McNary pool seems likely and would impact threatened salmonids from both Snake River and upper Columbia River sources.	The analyses of effects of breaching the four lower Snake River dams to Snake River resident fish communities is found in Section 3.5.3.6 under Region C of the Draft EIS beginning on page 3-585. Generally, there would be short-term adverse effects to the entire fish community due to breaching construction activities, and in the long-term the community would revert to a more native-dominated community than it is currently, due to the change from reservoir to riverine habitats. The effects to resident fish in the McNary pool is described in Section 3.5.3.6 under the subheading "Chief Joseph to McNary Dam" under Region B. The shift in fish communities in the Snake River would not be expected to be displaced to the Columbia River, but rather just shift over time after the initial short-term adverse effects. Sediment loads to the Snake and Columbia rivers that could occur under the MO3 Breach Snake Embankments measure were analyzed using water quality and sediment transport models as described in Appendices B and C. The sediment impounded behind the four lower Snake River Dams is predominately fine grained and readily transported in suspension. Analysis results for the MO3 Breach Snake Embankments measure indicate that increased sediment concentrations could occur during the two-year construction season with major changes to dissolved oxygen as described in Section 3.4.1 of Appendix C. Mitigation actions to address these potential effects are described in Chapter 5.4.3. Modeling suggests that impounded sediments within the historical river channel extents would scour back to the historical river-bed elevations over the near-term depending on the magnitude and duration of watershed hydrology. Impounded margin sediments remaining on higher elevation floodplain terraces would be expected to incrementally erode over a longer decadal time frame as seasonal floods access those surfaces. The effects on river mechanics are described in Section 3.3.3.5.3.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
2817	4	dick.Ledgerwood@gmail.com	N/A	Following drawdown, an increase in GHG emissions from gas fired plants and increased regional truck and rail traffic will further contribute to climate change at a time when the world is desperate to curtail these emissions. A warming climate is causing loss of the snow pack. If we lose the snow pack we also lose the fish that depend on melting snow to carry them to sea	The agencies analyzed impacts to greenhouse gas emissions, which are identified in Sections 3.8 and 7.7.10. Effects to alternatives and resources from projected changes in climate are analyzed in Chapter 4 and Section 7.8.
2828	1	uniontowntownhall@gmail.com	Town of Uniontown	Please see attached scanned letter.	Unfortunately, an attachment was not received from the commenter. The co-lead agencies requested the commenter resubmit via e-mail on June 25, 2020; however, the co-lead agencies did not receive a response to this request.
2836	1	N/A	N/A	It appears that the EIS fails to address the current and future impact of the fishery on an economic level and also fails to address the smolt return numbers to ensure future returns.	Section 3.15 considers the social and economic values related to fish, and how they may be affected by the CRSO alternatives. The effects of the CRSO alternatives on potentially affected fish species are presented in Section 3.5. Section 3,15 references those results in addressing how the commercial and ceremonial and subsistence fisheries that depend upon those fish species may be affected by the alternatives. The potential impacts to recreational fisheries are described in the Recreation / Environmental Consequences section. Smolt to adult return rates (SAR) were a primary metric in evaluating the effect of alternatives on salmon and steelhead. Section 3.5 describes the two peer-reviewed models used to estimate this metric, and presents the results for each alternative. Section 7.7.4 presents SARs for the preferred alternative. In our analysis of effects, the co-lead agencies used high quality data and best science, including models and studies published in peer review science journals. Based on our analysis, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery.
2845	1	Scott Rhees	Franklin PUD	The LSR Dams are a critical element to providing zero carbon electricity, which helps many utilities achieve the standards put forth in Washington's Clean Energy Transformation Act (CETA). Removing the dams would actually be counterproductive to the growing worldwide initiative of carbon emission reduction without scientific facts that there would be any restorative benefit to the wildlife in question.	The EIS does consider the emissions benefits of hydropower, finding that greenhouse gas emissions would increase under MO3, making it more difficult to achieve state emissions reductions goals. The effects associated with MO3 for fish are described in Section 3.5 of the Draft EIS; and Section 3.6 describes the effects associated with MO3 for wildlife. The Preferred Alternative does not recommend breaching the four lower Snake River dams, a measure that is evaluated in MO3.
2845	2	Scott Rhees	Franklin PUD	The DE IS Preferred Alternative does recommend increasing spill to help migrating salmon. Studies have shown that the nitrogen created by spill and becomes trapped in the water may kill more fish than the spill helps. Too much spill can also negatively impact adult returning salmon by making it difficult for the salmon to find the fish ladders. Flexible spill is still in its infancy and should be fully analyzed to determine the impacts before adding additional spill.	The co-lead agencies used the most current, high-quality, available scientific information and appropriate modeling tools in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and would average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan, including monitoring to track the effects of dissolved gas levels on juvenile and adult fish, to help narrow the uncertainty between the two models and determine how effective increased spill can be for salmon and steelhead returns to the Columbia River Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
2845	3	Scott Rhees	Franklin PUD	Animal predation mitigation was not included in the DEIS Preferred Alternative but should be considered.	Ongoing actions described in Section 2.4.2 of the No Action Alternative to reduce predation on migrating fish are included in the Preferred Alternative and are described in Section 7.6.4.1, Table 7-5 in the Draft EIS. In addition, the operational measure Predator Disruption Operations in the John Day reservoir is expected to further reduce avian predation on migrating juvenile fish as described in Section 7.6.3.16 in the Draft EIS.
2845	4	Scott Rhees	Franklin PUD	While the DEIS Preferred Alternative is believed to meet the objectives of the Environmental Impact Study Franklin PUD feels that animal predation and the impacts of increased spill should be considered in more detail before the final plan is adopted.	Ongoing actions described in Section 2.4.2 of the No Action Alternative to reduce predation on migrating fish are included in the Preferred Alternative and are described in Section 7.6.4.1, Table 7-5 in the Draft EIS. In addition, the operational measure Predator Disruption Operations in the John Day reservoir is expected to further reduce avian predation on migrating juvenile fish as described in Section 7.6.3.16. Using the most up-to-date, high-quality available scientific information and appropriate modeling tools agreed to by co-leads and cooperating agencies, the effects of spill have been evaluated and described for the Preferred Alternative. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the biological models and to will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
2864	1	jerryduling@gmail.com	N/A	As a director for Wasco Electric Cooperative as well as a self employed farmer in north central Oregon, I would like to comment in opposition to breaching the dams on the lower Snake River and in favor of the lead agencies preferred alternatives.	Thank you for your comment.
2864	2	jerryduling@gmail.com	N/A	The members of our Coop desire affordable and reliable power and beaching the dams would affect both. As a farmer, this could be devastating to our way of life. We depend on the transportation, affordable power and water storage. Our margins are very small and we can not afford the associated costs of removing the dams. We have invested heavily in protecting salmon by reducing our carbon footprint by switching to no-till practices and precision agriculture which have reduced our carbon footprint and reduced sediment and pollutants in our streams. The benefits are just beginning to be recognized. The costs of beaching the dams far outweighs the benefits especially when the science behind it is unproven.	Section 3.10 of the Draft EIS describes the commercial and regional importance of the Snake River as part of the Columbia Snake Navigation System, as well as its relative efficiency, low costs for shippers, and relatively low air emissions relative to other transportation modes. The EIS acknowledges that depending on how rail rates respond to dam breach, shortline rail capacity could be exceeded. The EIS also evaluates the additional transportation infrastructure investments that would be required, as well as the increases in air emissions that would occur. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted. Note, cost scenarios for specific farmers are presented below in the Regional Economic Effects within Section 3.10.3.5. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170 in the Draft EIS), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
2878	1	N/A	N/A	The DEIS must include a comprehensive economic analysis of Idahos salmon sport fishery and its potential in the event of restored abundant wild salmon and steelhead returns.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The recreation analysis for the EIS considered the broad range of recreational activities supported by the region, including recreational fishing. While the analysis described any potential impacts to recreational fishing visitation, the EIS did not estimate these impacts separately from the overall impacts to recreation, or estimate changes in fishing visitation related to changes in fish abundance. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which are described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
2878	2	N/A	N/A	MO3 is the only alternative that adequately minimizes the risk of extinction for Snake River stocks as a baseline; something legally required of this DEIS.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Based on the anadromous fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery determinations are ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve more parties than just the co-lead agencies across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
2878	3	N/A	N/A	Alternative MO3 needs to include an accurate cost-benefit analysis of the four Lower Snake River dams and the power they generate	The EIS evaluated beneficial and adverse effects across an array of affected resources including potential effects at the national, regional and local level. The EIS does not employ a cost-benefit framework for decision-making consistent with NEPA (see 40 C.F.R. 1502.23). The beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. While a cost-benefit analysis is not performed, the EIS analysis included a thorough analysis of quantifiable impacts for each MO, including impacts on power generation. For MO3, the costs of replacing the lost generating capability of the four lower Snake River dams is discussed in Section 3.7.3.5, Lower Snake River Replacement, page 3-905 in the Draft EIS. The rate impacts from these replacement resources, which includes cost savings from breaching the four lower Snake River dams, is described in Section 3.7.3.5, Table 3-166, pages 3-920-924 in the Draft EIS. As described in the EIS, even with the cost savings associated with reductions in dam operating and fish and wildlife mitigation costs, the net impact on power rates from the breaching of the four lower Snake River dams range from increases of 13-50% (for zero carbon resources replacements) to 4-10% (for natural gas/least cost replacements). The power analysis, described in Section 3.7 and Appendix H, includes additional discussion of the range of costs and benefits associated with MO3, the alternative that includes breaching of the four lower Snake River dams.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
2878	4	N/A	N/A	The DEIS needs a more thorough economic analysis on the benefits of a restored Lower Snake River corridor.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MO), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. Under MO3, the EIS Section 3.5.3.6 describes the long-term effects to anadromous fish migration in Region C that would occur under a dam breach scenario as major and beneficial. The potential for increases in recreational fishing under MO3 in Region C, which would support jobs, income, and social benefits in Tribal and rural river communities, is described in Section 3.11.3.5. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users.
2880	1	N/A	N/A	I am a member/consumer of Midstate Electric Cooperative (MEC), a not-for-profit, member-owned electric cooperative headquartered in La Pine, Oregon.: 91.3%] [Form The cooperative purchases 100% of our power from the Bonneville Power Administration (BPA) to provide electric service to over 36,000 people and 2,000 businesses in four counties in Central Oregon.: 87.5%] [Form MEC agrees that Multiple Objective 3 (MO3) breaching the four lower Snake River dams (LSRD) would have an adverse impact on electric cooperative consumers, the reliability of the Northwest energy grid, and the global environment.: 97.1%	The comments that breaching the four lower Snake River dams would (a) increase the frequency of power shortages unless and until replacement resources were built, and (b) would result in increased costs in the region, are both consistent with EIS findings. See EIS, Section 3.7.3.5, Table 3-166 in the Draft EIS; see also Appendix H, Table 2-1. The EIS also finds that Bonneville Power Administration (Bonneville) customers, such as cooperatives mentioned by the commenter, may be more directly affected by rate pressures than other regional utilities that do not purchase power directly from Bonneville. See Draft EIS, Section 3.7.3.5, Residential Effects, page 3-929.
2880	2	N/A	N/A	We are pleased that the DEIS rejected the dam breaching option based on the conclusion that it has the highest adverse impacts to other resources, especially social and economic effects. We are also pleased that the DEIS rejected Multiple Objective 4 (MO4), which significantly increases spill and dramatically decreases power production.	Thank you for your comment.
2880	3	N/A	N/A	The DEIS concluded that breaching the LSRD would have long-term, major, adverse effects on power costs and rates, and the rate pressure could be up to 50% on wholesale power rates. Increased spill as envisioned by MO4 would also increase costs up to 41%.: 100.0%] [Form A 40-50% increase in BPAs rate could lead to an increase of several hundred dollars a year to us, their members.: 100.0%] [Form The most impacted by these rate increases will be our vulnerable populations senior citizens and those on fixed incomes who shouldnt have to choose between medicine, food or paying their electric bills.:	The comments that breaching the four lower Snake River dams would (a) increase the frequency of power shortages unless and until replacement resources were built, and (b) would result in increased costs in the region, are both consistent with EIS findings. See EIS, Section 3.7.3.5, Table 3-166 in the Draft EIS; see also Appendix H, Table 2-1. The EIS also finds that Bonneville Power Administration (Bonneville) customers, such as cooperatives mentioned by the commenter, may be more directly affected by rate pressures than other regional utilities that do not purchase power directly from Bonneville. See Draft EIS, Section 3.7.3.5, Residential Effects, page 3-929. The Environmental Justice analysis (Section 3.18.3 of the Draft EIS) provides further detail on potential disproportionate effects to Tribal, low-income and minority populations.
2880	4	N/A	N/A	MEC also takes seriously their commitment to keep our lights on.: 90.9%] [Form The DEIS concludes the dam breaching alternative would more than double the regions risk of power shortages. MO4 creates an even higher risk of brownouts and blackouts in the Pacific Northwest, which again would harm our co-ops most vulnerable populations.	The comment that breaching the four lower Snake River dams would increase the frequency of power shortages unless replacement resources were built is consistent with the EIS findings. If sufficient replacement resources are acquired, the risk of power shortages can be restored to close to the No Action Alternative level, though the cost of such replacement power would likely result in substantial upward rate pressure on Bonneville ratepayers. See Draft EIS, Section 3.7.3.5. The EIS also finds that Bonneville customers, such as cooperatives mentioned by the commenter, may be more directly affected by rate pressures than other regional utilities that do not purchase power directly from Bonneville. The information provided in the comment regarding the power-related impacts of MO4 is consistent with the findings of the EIS. See Draft EIS, Section 3.7.3.6. Consistent with the comment, the Executive Summary and Chapter 7 explain why MO4 does not meet the EIS objectives to maintain an adequate, efficient, economical and reliable, affordable power system.
2880	5	N/A	N/A	Oregons electric cooperatives are proud of our clean energy profile, with a power supply that is consistently over 90% carbon-emission free.: 95.7%] [Form According to the DEIS, breaching the dams would create an additional 3.3 million metric tons (MMT) of CO2 - a staggering 10% increase in power-related emissions across the Northwest.: 100.0%] [Form MO4 shows similar carbon impacts.: 100.0%] [Form The DEIS clearly demonstrates that breaching the LSRD or spilling excessive amounts of water would be a step backward from decarbonization efforts in our region	The 3.3 million metric ton CO2 increase in greenhouse gas (GHG) emissions under MO3, a 9% increase in regional power sector emissions, described in this comment is associated with a scenario in which only natural gas resources are developed or acquired to offset losses from the lower Snake River dams. The analysis additionally considers a scenario assuming all renewable replacement resources (at a higher cost as discussed in Section 3.8). Under this scenario, the analysis finds a 2.7% increase in regional CO2 emissions relative to the No Action Alternative. Given that policy and legislative decisions in Oregon and Washington are targeting large reductions in GHG emissions, the EIS describes that even the 2.7% increase in CO2 emissions makes these goals more difficult to achieve. The Preferred Alternative estimates that GHG emissions would increase by 1.5% or 0.54 million metric tons compared to the No Action Alternative.
2880	6	N/A	N/A	The DEIS also noted that the co-lead agencies have made substantial improvements for fish passage at the LSRD and lower Columbia River dams.: 100.0%] [Form Our cooperative has helped fund this multi-billion-dollar effort to improve fish passage at the dams, which is meeting targets of 96% survival rates for migrating juvenile fish.: 100.0%] [Form We believe that it is important to build upon this successful fish passage program instead of taking the drastic measure envisioned in MO3 and MO4.	Thank you for your comment.
2931	1	N/A	N/A	The DEIS preferred alternative does not provide sufficient indicia that it will prevent extinction or significant harm to existing the salmon and steelhead in the system. It also is unlikely to comply with the legislative mandates set forth in the Endangered Species Act.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets. Chapter 8 demonstrates the co-lead agencies' compliance with applicable laws, including the ESA.
2931	2	N/A	N/A	The Snake River Basin is likely to provide the best real chance for meaningful salmon and steelhead recovery in the entire Columbia Basin, due, in large part to the amount of coldwater habitat. Applying scientific analysis to the possible solutions, the best course of action is demonstrably the removal of all four of the lower Snake River dams. The result would be a massive recovery in the salmon and steelhead fishery, which would in turn benefit the whole ecosystem and local economy. The DEIS underestimates the benefits that would result from the removal of all four dams with regard to restoration of the fishery.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3, which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase smolt-to-adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River spring/summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SARs increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other.
2931	3	N/A	N/A	Strong and healthy fisheries result in strong and healthy ecosystems, a better quality of life for residents, and long term economic benefits. Dam removal has consistently been proven a viable and efficacious means of restoring fisheries across North America. The final EIS should include a preferred alternative that includes removal of the lower Snake River dams. The recovery of the fishery is unlikely if the dams are not removed.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets.
2939	1	jimricketts325@gmail.com	N/A	I am writing in supports the science-based solution of dam removal one of the options that was legally required to be evaluated and the only option with the potential to achieve recovery. The final EIS should include a preferred alternative that includes removal of the lower Snake River dams. Recovery of abundant, healthy and harvestable levels of Snake River salmon and steelhead is not achievable with the dams in place, as several decades of failed recovery efforts and billions of dollars have revealed. Now, at a time when infrastructure projects are finally getting attention that they desperately need, the agencies should call on Congress to make the necessary investments to replace the dams benefits so we can both recover the fish and maintain a vibrant regional economy.	The co-lead agencies used a multi-disciplinary and science-based approach to analyze the alternatives in the EIS analysis. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
2946	1	Robert Ward	Palouse Regional Transportation Planning Organization	Given the high societal costs of dam breaching, the decision on a Preferred Alternative that keeps the dams, but increases spill (i.e., water going over dams instead of through turbines) across the eight dams on the lower Columbia and Snake rivers is a reasonable alternative to improve fish migration. The idea to help juvenile migrating salmon avoid hydro turbines seems more practical than dam breaching. However, we recommend looking further into this option to see how effective this would be as the nitrogen trapped in the water by the spill may be harmful to fish.	The co-lead agencies used current high quality information and the best available science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. This monitoring program will include substantial monitoring efforts to track the effects of dissolved gas levels on juvenile and adult fish.
2948	1	markfccim@gmail.com	N/A	This was an opportunity to contribute to the economic development of the region. The costs of the dam removal will be large. When factored in the the "forever" time frame. it is a "drop in the bucket". As a model, look at the removal of the Elwa. The Benefit to the regional economy, and region are substantial.	The costs to breach the dams and draw down the infrastructure are described in Section 3.19 and in Appendix Q (construction costs of the structural measures). These construction costs have been annualized with the water resources fiscal year 2019 discount rate over the 50-year period of analysis. The social welfare and regional economic benefits in the long term under MO3 have been described in the recreation section (Section 3.11) and fisheries and passive use (Section 3.15). However, the uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, limits a quantitative analysis of the specific impacts of each alternative on these values. Because the effects on fish were not quantified, the EIS did not quantitatively evaluate fisheries. The social welfare effects under MO3 on fisheries are described as major and beneficial in the long-term, with increases in regional economic effects if commercial fish catch rates increase. For the effects on recreational fishing under MO3 (Section 3.11), the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in the lower Snake River. There is uncertainty around recreational and commercial fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. However, the EIS does describe that the visitation in the long-term, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting tourism businesses.
2954	2	N/A	N/A	Small river towns in Idaho rely on the salmon for their outdoor recreation industry, and generate $7.8 billion in consumer spending annually. This also provides 78,000 jobs and $2.3 billion in salaries and wages spread over the state. The dams on the LSR only provide 4% of the needed power to this region. Studies by the NW Energy Coalition indicate that power from the LSR dams can be replaced by new renewable resources such as wind and solar with little or no increase in rates or greenhouse gases.	The EIS recognizes the value of recreational and commercial fishing to the region. Section 3.15 describes the values associated with fisheries in the Northwest. Section 3.11 characterizes the sportfishing economy in the region. However, the uncertainty regarding the overall effects of the alternatives on regional fish populations, and how such changes may affect the management of the fisheries, limits a quantitative analysis of the specific impacts of each alternative on these values. The effects are therefore discussed qualitatively. The social welfare effects on fisheries under Multiple Objective Alternative 3 (MO3) are described as major and beneficial in the long-term, with increases in regional economic effects if commercial fish catch rates increase. For the effects on recreational fishing under MO3 (Section 3.11.3.5 in the draft EIS), the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River). While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the FCRPS from which Bonneville markets power. As described in Section 3.7.3.5 of the draft EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are among the most valuable projects in the Federal Columbia River Power System (FCRPS). These dams provide over 1000 MW of carbon-free energy and up to 2000 MW of sustained peaking capacity at certain times of the year. The dams also provide important ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to approximately 2,300 MW of capability in certain months of the year (see Table 3-160 in the draft EIS). In addition, the EIS finds that, even assuming renewable resources replace the reduction in capacity under MO3, there would be an increase in regional greenhouse gas emissions. As described in Appendix H, Power and Transmission and Section 3.7.3.5 in the draft EIS, the EIS considered the NWEC study cited by the commenter but it is not directly comparable with the EIS. This is due to a variety of reasons including that the EIS has a broader scope and relies on more recent regional load and resource availability and costs data.
2954	3	N/A	N/A	The DEIS falls short of recommending dam breaching on the Lower Snake, which is the preferred action by scientists to help restore the salmon. Over $17 billion have been wasted as well as precious time in which we could have spent tax payers dollars more wisely and helped fishing communities along the coast. The federal agency approach only maintains a status quo and fails to resolve the core of the problem. 1) In the DEIS, a number of alternative strategies are listed. The Corps, Bureau and BPA have picked MO4. With respect to Columbia Basin salmon and steelhead recovery, the CRSO-DEIS preferred alternative (MO4) basically calls for a continuation of the status quo on the lower Snake River and lower Columbia River system and is, therefore entirely inadequate. 2) As stated in Chapter 2 of the Comparative Survival Study (CSS) Annual Report for 2019, "Among the federal alternatives, MO3 (the four dam breach alternative) resulted in the highest SARs(Smolt to Adult Return) and in-river survivals In light of looming salmon and steelhead extinctions, MO3 (4-dam breach) must be implemented. Nothing less will enable fish survival. 3) The time has come for our 3-state governors and members of Congress to take leadership on this issue. The DEIS preferred alternative makes clear that our Federal agencies have failed to dramatically change course in order to meet the Northwest's fish-recovery challenge.	Your comment indicated that you believe and did not support alternative MO4 as the Preferred Alternative. The Preferred Alternative is described in Chapter 7, including a description of the measures being used and the rationale for why other alternatives, including MO4, were not selected as the Preferred Alternative. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Moreover, the co-lead agencies disagree the Preferred Alternative is a continuation of the status quo. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The Preferred Alternative also includes other operational, structural and mitigation measures to improve conditions for ESA-listed salmon and steelhead. Finally, the commenters suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).
2956	1	N/A	N/A	The preferred alternative would increase spill to 125% of total dissolved gas (TDG) levels, which is higher than the previous limit. Scientific study and expert opinion have concluded that TDG limits above 115% can be harmful to fish. There is no documentation to show whether a higher level of TDG would be beneficial to fish passage. More study and monitoring are clearly needed before the 125% TDG limit is incorporated into the operation of the dams	TDG levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment, Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, supported by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects; and therefore, monitoring is required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. Further, the Preferred Alternative includes a robust monitoring plan to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored.
2956	2	N/A	N/A	The costs associated with construction and operational changes to implement the preferred alternative should NOT be allocated exclusively to power rates and thus paid primarily by public power users in the Northwest. Since protection of fish and wildlife is a regional issue, the associated costs should be borne by all residents of the Northwest.	Bonneville is statutorily obligated to pay for its share of project costs, including fish mitigation. Bonneville's share of project costs are established by existing cost allocations at each FCRPS dam. The report on the House Energy and Water Development Committees Appropriations Bill for Fiscal Year 2020 includes language that directed the Corps, Reclamation, and Bonneville to jointly develop an outline for conducting cost allocation studies for relevant projects within the FCRPS. The outline must include a prioritized list of projects for which cost allocation studies should be conducted and the scope necessary to perform the study. Once the outline is complete, the co-lead agencies are required to brief the Committee with the results. Work is underway on this outline, but whether any new cost allocation studies would be developed as a result of this process is speculative. Thus, the cost analysis provided in the EIS focuses on the current cost allocations. The cost allocations used in this EIS were developed based on methodologies adopted by Corps and Reclamation and reflected in their policies. Although each methodology has a different approach, the fundamental goal of any cost allocation is to allocate a share of the projects costs (capital and O&M) to each of its authorized purposes (e.g., flood control, navigation, power, irrigation). Fish mitigation costs are assigned to each authorized purpose based on each purposes overall share of project costs, as determined by the cost allocation. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Although Congress authorized Bonneville to fund the power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992. (Energy Policy Act of 1992, Pub. L. No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)), in some situations, including the Columbia River Fish Mitigation program, Bonneville does not directly pay for the capital costs of fish mitigation structures; instead it reimburses the U.S. Treasury for the power share of appropriations used to construct the structure. Additionally, as described in Section 3.19 of the EIS and Appendix Q, funding to operate the system comes through multiple mechanisms, including Federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. For joint related costs, including funding for fish and wildlife mitigation actions, the Corps and Reclamation receive annual Congressional appropriations to fund most, if not all, capital investments. Bonneville reimburses Treasury for the power share of these appropriations. Once the investment is in place, Bonneville will typically direct fund the operations and maintenance costs associated with the facility. In addition to congressional appropriations for fish and wildlife, the Bonneville Fish and Wildlife Program funds hundreds of projects each year to mitigate the impacts of the Federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the FCRPS. This program is funded by Bonneville's electricity ratepayers as part of the rates Bonneville sets to recover its costs.
2956	3	N/A	N/A	The final alternative selected, like the preferred alternative identified in the draft EIS, should consider a full range of effects from the proposed actions beyond protecting fish and wildlife, including effects on transportation, agriculture, recreation, irrigation, and overall implementation costs.	The Preferred Alternative and all four Multiple Objective (MO) alternatives had a full assessment compared to the No Action and were comparable to each other. The final Preferred Alternative will come from these alternatives and therefore have a full analysis, including the implementation costs.
2956	4	N/A	N/A	Ocean conditions can significantly affect the survival of fish and wildlife. Pollution from pesticides and other sources present in the ocean may be a significantly greater problem than the dams themselves. A far better understanding of ocean conditions impacting fish and wildlife and possible mitigation strategies is needed before dam removal is given serious consideration.	The co-lead agencies agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. While none of the alternatives would affect ocean conditions and ocean conditions are outside of the scope of this EIS, we recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of this environment in the return of adult salmon and steelhead (Peterson et al. 2019). As such, two of the models used in these analyses, NMFS Life Cycle and CSS models, use metrics of ocean productivity to predict adult returns.
2956	5	N/A	N/A	The final alternative selected should ensure that each component of the plan, including fish hatcheries and ocean harvest quotas, makes a significant contribution to the goal of delisting threatened or endangered species.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The co-lead agencies agree that there are many effects to salmon and steelhead populations outside the operation of the dams. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the 2018 EIS from NOAA and reflect current harvest management guidelines. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and Tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and Tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so. However, based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The effects from the Preferred Alternative on anadromous fisheries are expected to be negligible in Region B downstream of Chief Joseph Dam due to minor changes in operations. As stated previously, depending on the model and ESU/DPS, the effects to anadromous fisheries in Regions C and D have the potential to range from moderate adverse effects to major beneficial effects. However, effects from the Preferred Alternative are expected to improve fish survival and abundance for both anadromous and resident fish through the combination of operational and mitigation measures. To the extent that increases in fish abundance occur, this would increase opportunities for tribal, commercial, and recreational fishing throughout the Columbia River Basin.
2956	6	N/A	N/A	As the population in the Pacific Northwest continues to grow, increased demand for electric power will occur. Meeting that demand can be accomplished with renewables, such as wind and solar, only if there is a base load resource to support them. Carbon free, renewable hydro power is a perfect fit to backstop the variable supply uncertainties associated with other renewables. 7) Industry experts are sounding the alarm that future demand for electric power will outstrip available supply as the Northwest closes coalfired power plants, leading to possible forced outages. This is NOT the time to remove carbon free, renewable hydro facilities like the dams on the lower Snake River. Instead, we should use those dams to meet the growing demand for electric power in the Northwest and to facilitate the integration of additional renewable resources to help meet grid requirements.	This comment is consistent with the findings of the EIS that the four lower Snake River dams provide carbon-free energy and play an important role in the regional power system, particularly in regards to the integration of renewable power sources.
2960	1	corso1965@live.com	N/A	Clearly, we can engineer a better solution to the challenges of irrigating farm land, generating electricity, transporting goods, and managing natural resources. Are we going to take the initiative to negotiate a solution that has something for all parties involved, or are we going to wait for a judge to order a solution without regard for our special interests? Remember the 1854-55 Stevens Treaties; Consider the smoldering Fish Wars; Reflect on court precedent. Is continuing business as usual worth risking loosing everything?	The co-lead agencies agree that there can be many challenges in operating a complex system to satisfy multiple sometimes conflicting purposes. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The co-lead agencies identified a reasonable range of alternatives after analysis of the Purpose and Need Statement and objects, coordination with the Cooperating Agencies, and public scoping. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the dam breaching alternative. However, the Preferred Alternative also meets most of the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.
2961	1	finney@isu.edu	N/A	DEIS makes it clear that removing the lower Snake River dams is the best option for Snake River salmon and steelhead, but substantially underestimates the level of benefit. The preferred alternative in the DEIS will not avoid extinction. There is a good chance it will not meet the requirements of the Endangered Species Act. This will likely land back in court and another cycle of expensive litigation and uncertainty. Time is running out if we want populations of these keystone fish to persist. Dam removal is a proven method to restore fish populations.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
2961	2	finney@isu.edu	N/A	The final EIS should include a preferred alternative that includes removal of the lower Snake River dams. Recovery of salmon and steelhead is not achievable with the dams in place. Snake River Basin has the greatest potential for wild fish recovery of any watershed in the Columbia Basin. It has the most undisturbed stream habitat and is predicted to contain the majority of coldwater habitat as the climate warms. Science consistently supports removal of the four Lower Snake River dams as necessary to recover populations of salmon and steelhead.	The CRSO EIS documents the assessment of benefits and impacts of changes to the operations of the 14 Federal projects of the CRS. Using a multi-disciplinary approach and with the coordination and consideration of our cooperating agencies and Tribes, as well as public stakeholder input, and by using high quality information, the co-lead agencies developed the Preferred Alternative. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. A full assessment of considerations of climate change and water temperatures are in Section 3.4 Water Quality, Chapter 4 Climate, and Chapter 7 of the Preferred Alternative of the analysis.
2987	1	N/A	N/A	The final EIS should include a preferred alternative that includes removal of the lower Snake River dams. Recovery of abundant, healthy and harvestable levels of Snake River salmon and steelhead is not achievable with the dams in place, as has been shown over the years and the billions of wasted dollars.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of NMFS and the US Fish and Wildlife Service. This EIS has been developed in consultation with National Marine Fisheries Service and USFWS to minimize impacts to affected ESA species and their habitats. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets.
3002	1	N/A	N/A	The Preferred Alternative in the Draft EIS does not adequately provide for salmon and steelhead populations because it will not improve smolt to adult turn rates (SARs) to levels identified by scientists as necessary for harvest or recovery. Harvestable populations need a SAR around 4%, meaning 4 adults return for every 100 juvenile fish that head to the ocean. Under the Preferred Alternative, SARs for Snake River spring Chinook will reach 2.7% at best. The predicted SAR is even lower for Snake River steelhead at 2.4%. At worst, The Life Cycle Model predicts an extinction trajectory under the Preferred Alternative with a SAR below 1%. I do not support the Preferred Alternative, or any other alternatives, that continue to contribute to the extinction of salmon and steelhead.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the EIS analysis of anadromous fish resources in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. National Marine Fisheries Services (NMFS) and U.S. Fish and Wildlife Services (USFWS) review the co-lead agencies' biological assessments and are responsible for making this determination. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies used high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. It should be noted that the 4% average SAR target referenced refers to the Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation, maintenance, and configuration of the 14 CRS projects.
3004	1	jswalton@roadrunner.com	N/A	While science consistently supports removal of the four Lower Snake River dams as necessary to recover healthy, fishable populations of salmon and steelhead, the DEIS underestimates the level of benefit of removing the lower Snake River dams. The DEIS preferred alternative does not provide assurance that it will avoid extinction, let alone recover Snake River salmon and steelhead to abundant, harvestable levels. There is a good chance it will not meet the requirements of the Endangered Species Act and result in further litigation. Dam removal is the best method to restore fish populations; this has been proven from Maine to the Olympic Peninsula of Washington State. The final EIS should include a preferred alternative that includes removal of the lower Snake River dams. The agencies should call on Congress to make the necessary investments to replace the dams benefits so we can both recover the fish and maintain a strong regional economy.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) are responsible for making this determination. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies used current, high-quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region). The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.

					The EIS studied breaching the four Lower Snake River Dams as part of the MO3. Many dam removal projects that have occurred across the United States have very different circumstances than what is contemplated in MO3. Recent examples of dam removals have little relevance or similarity to the four lower Snake River Dams. For example, the Elwha dam had no fish passage and provided no economic benefits. In contrast, the four lower Snake River dams provide both upstream and downstream fish passage, produce power, and provide navigation and recreation opportunities. For power, the four lower Snake River dams produce upwards of 1,000 aMW of power, which is approximately 11% of the average power produced by the Federal Columbia River Power System. See Draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. Losing this amount of power is equivalent to losing power capable of serving 730,000 homes in the Pacific Northwest. See Draft EIS, Section 3.7.3.5, Summary of Effect, page 9-935, noting that the loss of power generation from the four lower Snake River dams accounts for about 90% of the power loss in MO3. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the alternative that includes the measure to breach the lower Snake River dams. However, the Preferred Alternative also meets the other objectives of the study for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. The alternative that includes the measure to breach the lower Snake River dams, by contrast, has significant regional economic impacts and community effects, and meets only a small subset of the EIS objectives. Thus, the co-lead agencies did not recommend that alternative (MO3) because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
3014	1	N/A	N/A	The lower Snake River dams should be de-commissioned. This is the only alternative that will meet the essential goal of restoring salmon/steelhead. Agricultural commodities can move by other means than Snake/Columbia barge traffic. I urge you to take appropriate action, and withdraw and revise the EIS to include as preferred option the removal of lower Snake River dams.	Section 3.10 evaluates the increased cost of transportation as well as the increased number of truck trips that would be required if the four lower Snake River dams were breached in MO3. The EIS recognizes that transportation costs increases could decrease profitability of farming. The number of truck trips would substantially increase ranging from an additional 14,000 to 79,000 truck trips per year. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
3033	2	sweeted@smgazette.com	N/A	We could help the fish runs improved by removing sea lions and seals by whatever means it takes to reduce their numbers at the base of the dams where they lay and kill fish at such high numbers.	The No Action Alternative includes ongoing mitigation measures to haze and monitor pinniped predators. These actions would continue under the Preferred Alternative. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
3034	2	12tobias@gmail.com	N/A	I beleive we need to continue habitat restoration efforts along with improving predation issues from avians and non-native fish along with improvements to hatchery operations. These actions need to be coupled with a restored lower Snake River if we are to get fish back to Idaho in numbers that will be useful for guides and outfitters, tribal treaty rights, anglers spending money on gas, hotels, fishing shops, and restaurants.	The alternatives analyzed in the EIS include primarily operational or structural measures at the 14 projects sites. Where adverse effects to habitat would be anticipated as a result of implementing an alternative, habitat restoration was proposed. For instance, the Preferred Alternative added habitat mitigation for wetlands and riparian areas in the John Day reservoir and around Lake Roosevelt. The purpose of the EIS was to evaluate alternative ways to manage the 14 Federal projects and determine if a new operation or configuration of the projects could reduce adverse impacts of the system operations, meet the EIS Purpose and Need Statement, objectives, and meet all regulatory and statutory compliance requirements. In addition to routine operations and maintenance of the CRS, the co-lead agencies implement a number of actions and programs, intended to benefit ESA-listed species in the Columbia River Basin. To make the most of available funds, investments in fish and wildlife protection, mitigation and enhancements are prioritized based on biological and cost-effectiveness and their connection to mitigating for impacts of the CRS. In Chapter 7, Table 7-5 in the Draft EIS provides a summary of habitat measures that are carried forward into the Preferred Alternative, which includes measures such as tributary habitat improvements for both Chinook salmon and steelhead, estuary habitat implementation, and Dworshak Reservoir long-term nutrient supplementation program. Hatchery measures have also been carried forward into the Preferred Alternative. Examples of these measures included in Table 7-5 include the programmatic Federal Columbia River Power System (FCRPS) mitigation hatcheries and the safety net programs that continue to identify and plan to provide benefits to ESA-listed stocks at high risk of extinction. The Preferred Alternative also carries forward predator management measures described in Chapter 2 and Chapter 7. The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative actions that reduce pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
3053	3	meaganhitch@gmail.com	N/A	Scientists from the Fish Passage Center have stated that breaching all four of these dams would result in roughly 1 million adult Chinook salmon returning to the mouth of the Columbia River, providing significant relief for endangered Southern Resident orcas. As you know Chinook salmon are the orcas' primary food source from central California to the Salish Sea. And the Columbia Basin supports salmon runs that the orcas have relied on for centuries. Historically half of all the salmon returning to the Columbia Basin were bound for the Snake River. But after the river was dammed more than half a century ago, the wild salmon runs plummeted and left the orcas with fewer fish to eat. Despite the fish ladders and our current interim spill measures, dams continue to cause serious salmon declines by directly killing and preventing their migration. Breaching these dams will cut dam-caused mortality by at least 50%. What's more, these dams have flooded miles of spawning habitat, destroyed healthy riparian forests, and created lethal warm-water reservoirs. With climate change, the number of days where temperatures will reach deadly levels are expected to increase. Independent research has stated that removing these four dams will help cool the river.	Neither the modeling conducted for the CRSO EIS, nor Fish Passage Center modeling conducted outside the EIS process, indicates that breaching the four lower Snake River dams would result in 1 million adult Chinook salmon returning to the mouth of the Columbia River. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS concluded Multiple Objective 3 (MO3) would result in greater improvement to certain salmon species in the lower Snake River. It did not conclude there was greater certainty of that result in MO3 over any other alternative. The conclusions were based on the ranges predicted in two independent models that have different parameters and limitations in their predictive capabilities. Because of delayed response time in MO3, and the potential severity of the short-term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan, which is administered by U.S. Fish and Wildlife Service. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The EIS analysis indicates that under a scenario that breaches the four lower Snake River dams, the lower Snake River water temperature regime would reflect that of a natural river system, without the water temperature lagging effect that reservoirs create. Spring water temperatures would warm faster, while fall water temperatures would cool faster, as compared to current conditions. The EIS analysis also indicates that summer water temperatures would cool to a greater extent at night, but some exceedances in the 68F water quality standard would still occur, especially during hot weather events and likely future climate change conditions.
3064	1	farmernate10@gmail.com	N/A	I have seen first hand the effectiveness of fish friendly turbines (at the Idaho Falls power plant) and believe that we can and should utilize this technology in many more places than the current existing ones. We can utilize canal diversion structures all along the Snake and its tributaries to help provide inexpensive power to a growing population without adding pollution to the air and using fossil fuels.	The co-lead agencies agree that improved fish passage turbines can increase juvenile fish survival substantially. These turbines are planned for installation at Ice Harbor, McNary, and John Day dams in the next 20 years. Early testing at Ice Harbor Dam shows survival rates over 98 percent. The Draft EIS analyzed several ways to bypass juvenile fish around Columbia River System dams, from dam breach, to surface bypass and spill. In a sense, these are similar to "utilizing canal diversion structures" as the comment suggests, but also meet the biological criteria utilized though decades of research and development of fish passage at these dams.
3080	1	solimarfishjohn@gmail.com	N/A	I have not read an environmentally acceptable replacement for the hydropower from those four "run of the river" dams with navigation locks. How do you replace hydro of that cleanliness, thrift, volume, with fossil fuel, wind, solar, or nuclear power with zero environmental impacts that we don't know would be more revolting than those we have with the reservoirs and water we have and know?	The replacement resource scenarios described in Section 3.7.3.5 of the EIS are designed to ensure that the effect of breaching the four lower Snake River dams on regional power reliability is minimized to the extent possible, taking into consideration the costs. The EIS recognizes that there are multiple ways that the generation losses from the dams could be replaced and relies on the best information currently available to identify cost-effective replacement scenarios. The EIS also identifies that replacing hydropower with other sources of power generation would have adverse environmental effects, including increasing greenhouse gases and air pollutant emissions, consistent with the concern stated in the comment. If an alternative is selected that requires replacement resources, additional environmental review would be required. Appendix H, Section 2.2.4 in the Final EIS discusses the process for potentially acquiring new resources.
3080	4	solimarfishjohn@gmail.com	N/A	Make FERC require Idaho Power provide access to salmon above their dams. Find a way to plant salmon and steelhead in the Owyhee and trap them below the dam and put them above it. That would also require irrigation districts to make the Hood River type of diverters to keep smolts out of	The scope of the EIS focuses on the area affected by the alternatives presented for operating, maintaining, and the configuration of the Columbia River System projects. Idaho Power dams and their effects on salmon and steelhead are outside of the geographic scope of the project. Similarly, the co-lead agencies do not have the authority to direct FERC to require other entities to provide fish passage at their facilities.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				irrigation canals. Do the same on the Malheur river. It was called "stink river" by the French because of the stench of spawned out, dead chinook creating the "mal eau". bad water. Snake River chinook are not in short supply because of any Washington dam issue. Idaho never required fish ladders or dam designs that would pass salmon and steelhead upstream. So now no steelhead or salmon get to Nevada at all. Nor to most of their former habitat in Idaho.	
3080	5	solimarfishjohn@gmail.com	N/A	Orcas are eating the Puget Sound/Salish Sea chinook and starving their cousins. Sea lions and seals are compounding the problem. 4 dams on the Snake River in Washington are irrelevant to their survival. Best the proposed dam removal money be best spent on creating a chinook hatchery program around lower BC and Puget Sound that produces spring, summer, fall, and winter returning races of chinook salmon.	The No Action Alternative includes ongoing mitigation measures to haze and monitor pinniped predators. These actions would continue under the Preferred Alternative. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The co-lead agencies conclude there could be a negligible to minor beneficial effects to SRKW from implementing MO3. CSS and NMFS Lifecycle models predict that lower Snake River Chinook salmon smolt-to-adult returns would have a moderate to major increase under MO3. Operation of Lower Snake River Compensation Plan fish hatcheries under MO3 is uncertain and therefore, production of Snake River hatchery fish is assumed to decline over the long term, while returning adult wild salmon are anticipated to increase. However, the co-leads do not anticipate a lack of hatchery fish in the short term based on the proposed fish hatchery mitigation described in Chapter 5. These additional hatchery fish should mitigate short-term construction effects to Snake River populations. Additionally, to address short-term effects to ESA-listed species, the co-lead agencies propose constructing a new trap and haul facility at McNary and conducting at least two years of trap and haul operations for Snake River fish (Chinook, sockeye, and steelhead). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by USFWS. Hatchery programs in lower British Columbia and the Puget Sound area are outside the scope of the EIS.
3084	1	N/A	N/A	Dam removal is a poorly thought out plan that will bring on widespread power shortages across the Pacific Northwest. Brownouts or shut downs are totally unacceptable for today's Oregonians. The reasons listed below are but a short list. There is no plan in place to replace this 24 hour power supply. The coal fired plants and nuclear plants are being phased out at the same time. Wind and solar are intermittent sources and can never replace water power. Solar or wind cannot be stored effectively at this time.	The comments that breaching the four lower Snake River dams would increase the frequency of power shortages unless replacement resources were built are consistent with findings in the EIS. See Draft EIS, Section 3.7.3.5, Effects on Power System Reliability, page 3-903; see also Appendix H, Table 2-1. The EIS does find that regional reliability can be restored with variable renewable resources like wind and solar, but at a considerable cost. See Section 3.7.3.5, Table 3-166 in the Draft EIS. However, the EIS did not evaluate whether there would sufficient dispatchable resources to provide the balancing services needed for integrating variable resources to both replace the generation of the four lower Snake River dams and the retiring coal plants.
3107	1	dbelenky@yahoo.com	N/A	My comment refers to Alternative 3 (MO3) developed to evaluate breaching the four Lower Snake River dams (Lower Granite, Little Goose, Lower Monumental and Ice Harbor). I believe a new alternative similar to MO3 (hereinafter MO3Nuclear) should be devised which would address the need to replace the lost hydropower, the lost navigation/transportation, and the lost irrigation resulting from the breaching of the four dams. As MO3 is by far the superior alternative relative to the preservation of endangered species, the additional cost of MO3Nuclear should be considered an acceptable tradeoff. The four dams currently have a nameplate capacity of 3033MWe (Megawatts electric) with a maximum push capacity of 2650MW x 10 hours per day for 5 days during a cold snap. If these were replaced by 3 x 1400MW nuclear reactors of the current standard, the equivalent or greater power would be available. The advantages of using nuclear rather than a combination of wind, solar and gas-turbine power are; 1) no CO2 output, 2) no danger to raptor species from high-speed wind-turbine blades, and 3) much small footprint and impact on the landscape. In addition Nuclear requires fewer resources of concrete, metal, semiconductors, glass and fossil fuels. The nuclear power could be used; 1) to replace the hydropower currently used by the BPA to supply the Tri-Cities and other current regional demands, 2) to electrify rail transport from Lewiston to Portland, thus reducing CO2 emissions and providing adequate replacement for lost navigation, and 3) to provide pump irrigation, reducing impacts on fish populations, and replacing current dam fed irrigation. MO3Nuclear is proposed to be sited close to to the current Energy Northwest facility outside of Hanford WA for the following reasons; From a national security and international relations point of view it is imperative that the United States re-assert its role as a dominant player in the expansion of nuclear power in the electrification and industrialization of the world. China and Russia are making a remarkable push into Africa, India, and many other areas. Were they to supplant the USA in this area it would affect US influence for decades, if not centuries to come. A small price to pay for supporting this industry. The know-how and infrastructure to support the nuclear industry exists in the Tri-Cities area. There are top-notch research facilities in the area. Many small businesses related to the nuclear industries reside around Hanford and the existence of a nuclear power plant in the area makes it a natural fit. The EIR alludes to insufficient electrical capacity from the Ice River Dam area to the Tri-Cities. Expansion of high-tension lines could be avoided with this proposal. By siting these plants in conjunction with Energy Northwest, operational efficiencies could be gained by using the same management and cross-training manpower. Additionally to allow for future growth, the basic infrastructure could be planned as a six pack of plants with the intention to accomodate an expansion to 6 reactors in the future should it become advisable as population grows in the cities of the Northwest. Six-packs have been found to be a favorable and efficient arrangement by operators in Japan, Korea and China. Another advantage of the six-pack arrangement is that any excess energy could be used to replace Columbia River dam power thus allowing for removal of other obstructing dams along that watercourse allowing for additional species restoration. If water withdrawals from the river for cooling were found to be excessive, this should not be an impediment as either; 1) seasonal dry-cooling could be part of the design as is done at nuclear plants in Kazakhstan or, 2) the use of reclaimed waste-water from the Tri-Cities could be used as is done in Phoenix by the Palo Verde nuclear plant. While this alternative may be considered expensive I believe the funding could be justified by the value of the species restoration. The value of the rail electrification should be included too. The State Department and Department of Defence should also be considered as funding sources for the international relations and national defense value of this proposal.	The comment suggests replacing the output of the lower Snake River dams with nuclear power and describes a range of potential benefits of this development alternative. In considering power replacement portfolios, the EIS focuses on technologies that are currently in operation and are capable of utility-scale performance. The source of resource information used in the EIS is the Northwest Power and Conservation Council's 7th Power Plan and Mid-term Update. Conventional nuclear power units, as described in the comment, are not considered viable by the Council given various risks. The Council considers small modular nuclear reactors potentially viable as they address many of the risks identified with larger conventional nuclear units as described in the 7th Power Plan. For MO3, the EIS did consider small modular nuclear reactors (SMR) as a potential replacement for some of the attributes of the four lower Snake River dams and costs estimates were provided. See Draft EIS Section 3.7.3.5, Small Nuclear Reactor on page 3-909. However, as noted in the Draft EIS, the ramping capability of SMR is unknown. Thus it is unknown if a SMR would be able to provide ramping capability similar to the lower Snake River projects at this time. See Draft EIS on page 3-910. Appendix H provides further discussion on the selection of replacement power resources. If an alternative is selected that requires replacement resources, whether solar, wind, nuclear or other resource, additional environmental review would be required. Appendix H, Section 2.2.4 in the Final EIS discusses the process for potentially acquiring new resources.
3112	1	mark.frei30@gmail.com	N/A	As a farmer, I depend on the navigation system to get my crops to market outside of the state, and without the dams the transportation cost of my wheat to market would make the crop entirely unprofitable for my farming operation. The transportation of wheat cannot be shifted to rail and truck economically, and it would greatly increase fossil fuel consumption.	The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. Evaluating the impact of removing the lower Snake River locks and barge navigation above Pasco, Washington, is completed using a transportation optimization model that does not allow shipments on river terminals along the lower Snake River. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33%, but that individual farmers could experience costs that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely impacted. Note, cost scenarios for specific farmers are presented in the Regional Economic Effects within Section 3.10.3.5.
3119	1	court.olson@yahoo.com	N/A	I am convinced that we dont need the Lower Snake dams for a reliable energy future. [FYI, buildings account for over 75% of the power consumption on our electric grid. The potential for energy efficiency improvements in our buildings is huge. Given new legislation just passed in Washington, when deeper efficiency measures and increased peak demand controls are aggressively pursued, as I expect they will be, I believe that we can offset the newly developing trend toward abandonment of natural gas usage and replacement with heat pump technology. Consequently, I dont believe that well see significant long-term growth in electric power peak demand. Meanwhile, renewable wind and solar resources will be coming online across the Northwest region to help in this transition.] Given the direction of the energy transformation that I see, the CRSO EIS appears to overvalue those dams for our future power needs.	The comment regarding the importance of the lower Snake River dams to the regional power system is inconsistent with the findings of the EIS. As explained in Section 3.7.3.5 of the Draft EIS, Potential Replacement Resources and Associated Costs, breaching the four lower Snake River dams would have a direct and substantial impact on the supply of Federal power to meet regional load requirements and adversely affect regional power reliability. In addition, the four lower Snake River dams provide carbon-free energy and play an important role in the regional power system, particularly in regards to the integration of renewable power sources, which, as described by the comment, are likely going to increase in the future. Regarding the potential for additional efficiency, the EIS included all cost-effective conservation identified by the Northwest Power and Conservation Council in the 7th Power Plan, which is the current power plan. Cost-effective conservation in the region will be acquired pursuant to current law regardless of the status of the four lower Snake River dams. In addition, substantial amounts of regional coal generation will be retiring over the next decade. See Draft EIS, page 3-841. Without replacing these resources, regional power reliability would decrease substantially.
3126	1	kenboire@aol.com	N/A	This document seems inadequate regarding treatment of reintroduction of salmon above Grand Coulee Dam and installation of fish passage at Grand Coulee and Chief Joseph Dams. Because the concept of reintroduction is casually dismissed, this document disregards potential measures that could make up the most likely, most productive, most acceptable, most economic means of increasing salmon stocks. Mitigation does not have to be in the	Measures to reintroduce salmon above Chief Joseph and Grand Coulee dams were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important, complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple Tribal, Federal, state, and other entities. A coordinated approach among water users, Tribes, states, multiple Federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				same stream and reach as losses. By opening the basin above Grand Coulee, historical critical fish habitat would be restored to reestablish anadromous stocks. The reasons given for not dealing with this are like saying Well we dont have the data, we dont know the science, and it would be too much work but we can just do it later. A casual look at practically any map quickly reveals the amount of river basin and habitat that would be added above Grand Coulee in the USA and Canada would be huge and probably be more than what could be added in the USA by removal of the Snake River projects. Sure, challenges of international cooperation would be encountered but the USA and Canada have already rationally faced fisheries issues regarding Pacific Salmon in border waters of Washington and Alaska. International cooperation needs to be part of this solution and it is embarrassing to find that in the more than 20 years since ESA listing, the Corps, Reclamation, agencies, tribes and industry have seemingly not moved ahead an inch. It is equally embarrassing to discover how reintroduction has been quashed in this EIS because of apparent agency fixation on components of other pet measures that have been under institutional study for longer than some careers. This is not to say the measures in the EIS are unsound, shallow, impractical or unworthy. They are clear and scientifically derived. The nature of an EIS is that it is supposed to recognize problems, measure them, and evaluate alternative solutions. This document deals with long-standing listed species and should at least present a side-by-side comparison of reintroduction with other alternatives like the graphic treatment in Crosswalk", Table 2-12. Obviously more study will be required to do this and the EIS budget and timeline would require modification in order to complete this EIS as a final report. But without this task the EIS is an empty document and someone might be able to argue it seems to fall short of the legal and scientific purpose. There must be a long history here. It is not a new issue. The challenges of passage, stocking and even reintroduction should have been hammered out starting in 1964 when some long-standing international dam issues were worked out for Canadian projects. Clearly somebody dropped the ball back then or sometime since. In over 50-years we should at least have a grasp adequate to proceed with a detailed consideration of reintroduction in this EIS. Reintroduction needs to be given serious treatment beyond saying agencies and interested regional sovereigns are developing a framework to address critical information gaps. As a minimum the EIS ought to include a budget and timeline of the in progress framework effort. Speaking of reintroduction, the EIS states "Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS." One reviewer found this to be outrageous. Contrary to being incompatible, the concept of reintroduction is essential as it could establish anadromous species in place of those made extinct by the lack of passage at Grand Coulee and other dams upstream of Grand Coulee. Reintroduction could require major construction but cannot be dismissed on the grounds it is beyond the scope of analysis of the operation of CRS as the EIS includes a dam removal alternative which itself is a major construction project well beyond any strictly operational option. Analysis of reintroduction could be so productive as to tamp down the need for present day costly operational measures or modifications to the Snake River dams. In that sense consideration of reintroduction belongs within this EIS and in all respects is not incompatible.	objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the Columbia River System, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the co-lead agencies and interested regional sovereigns are developing a framework to address critical information gaps.
3127	1	N/A	N/A	The Draft EIS for CRSO is inadequate in the description of alternatives which minimizes the value of the analysis of alternatives and raises significant questions regarding the objectivity of the analysis. The underlying problem is inherent in the Columbia River System Biological Assessment [BA] (Appendix V), which when combined with the Fish and Wildlife Coordination Report (Appendix U) identifies unresolved environmental issues and concerns. In Section 1 of the BA, the report points out it is a requirement of the Endangered Species Act. The report states: Under Section 7(a)(2) of the Endangered Species Act (ESA) (16 U.S.C. 1536(a)(2) 1973), the Action Agencies are responsible for ensuring that their actions are not likely to jeopardize the continued existence of endangered or threatened species or result in the destruction or adverse modification of designated critical habitat. In Section 5.7 of the BA, the report concludes: Taken collectively the Proposed Action and conservation measures avoid or minimize adverse effects of the Proposed Action on EFH for salmon and will also minimize adverse effects of the Proposed Action on groundfish and coastal pelagic EFH. The Proposed Action carries forward many of the reasonable and prudent measures recommended by NMFS in the 2019 NMFS CRS BiOp. In contrast the Fish and Wildlife Coordination Report comes to a different finding. In the Executive Summary of that report the USFWS states: Since the CRSO has been in operation, the co-lead agencies have implemented conservation measures to protect, mitigate, and enhance fish and wildlife resources affected by project operations. However, the CRSO will continue to negatively impact fish and wildlife resources in the Basin, even with ongoing conservation measures in place. Furthermore, the Coordination Report states on page 46: The Service acknowledges the multiple authorized purposes of the Federal dams and reservoirs. However, the Services analysis found that proposed changes in dam configurations including operations and maintenance of the 14 Federal projects that comprise the CRSO will overall negatively impact, fish, wildlife, and plants in the Basin along with the natural capital they offer. The Service provided a series of conservation recommendations in six categories. No discussion of these recommendations appear in the DEIS. As the DEIS is currently presented, the Description of Alternatives discussion lacks a clear presentation of the existing conservation measures and any additional conservation measures that are anticipated as discussed in the BA. Therefore, the analysis of alternatives if flawed and incomplete.	Chapter 2 and Chapter 7 discuss the Multiple Objective alternatives evaluated in detail, including those measures that are in the No Action Alternative, and those measures that would be carried forward in the Preferred Alternative. The Biological Assessments included the Preferred Alternative measures from the Draft EIS, for consultation with the U.S. Fish and Wildlife Service (USFWS) and National Marine Fisheries Service (NMFS) to determine whether it would jeopardize the continued existence of ESA-listed species, or the destruction or adverse modification of designated critical habitat for those ESA-listed species. USFWS and NMFS may propose reasonable and prudent alternatives (RPAs) or reasonable and prudent measures (RPMs), depending on the conclusion reached in the Biological Opinions. If adopted by the co-lead agencies, these RPAs and RPMs will be incorporated into the Final EIS and Record of Decision to reflect those commitments. The Biological Opinions from NMFS and the USFWS are included in the Final EIS, Appendix V. The draft USFWS Coordination Act Report (draft CAR) was included in the Draft EIS (Appendix U) and discussed in Section 8.3.2, Fish and Wildlife Coordination Act of 1934, and covers more than ESA-listed species. The co-lead agencies considered the findings and recommendations while developing the Preferred Alternative, drafting the EIS, and developing mitigation measures for the effects of the alternatives (see Chapter 5). Chapter 5 provides an overview of possible mitigation measures being considered to avoid, minimize and reduce impacts to the environment associated with the No Action Alternative and four Multiple Objective alternatives (MOs). Additional mitigation associated with the Preferred Alternative is described in Chapter 7. See Section 7.6.4.1, Ongoing Programs, and Draft EIS Table 7-5, Measures Included in the Preferred Alternative to Benefit Endangered Species Act-listed Fish that are Being Carried Forward from Previous Commitments by the Co-Lead Agencies, which includes management of lands for fish and wildlife, fish and wildlife actions, Bonneville's Fish and Wildlife Program and Lower Snake River Compensation Plan, the Columbia River Fish Mitigation Program, and the Columbia River Tributary Habitat Program. The final CAR and co-lead agencies considerations and adoption of recommendations are included in the Final EIS. The co-lead agencies need to consider the actions outlined in the CAR.
3130	1	coolhluke37@yahoo.com	N/A	While the Preferred Alternative concludes that any increase in the cost of hydropower will be mitigated through cost cutting measures, historically, those "promises" have not been kept by regulators. This would likely result in higher consumer electrical cost during low spill intervals. Dams are a clean power-generating mechanism and should be used to the maximum possible. Based on this, this portion of the Alternative should be reevaluated.	For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7% relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control.
3130	2	coolhluke37@yahoo.com	N/A	Any material consideration in the EIS for "climate change" should be eliminated. Any change mankind can make to mitigate such changes are wholly foolhardy and pushed by those not based in reality but those of the technology-generation that believe in the total accuracy of models based on flawed assumptions that can never be verified in our lifetime.	The technical and policy elements of the Draft EIS are in full compliance with Corps policy and guidance for qualitative assessment of climate threats and their plausible effects and impacts. The primary controlling policy and guidance are the Corps' Climate Adaptation Policy Statement, signed by the Assistant Secretary of the Army for Civil Works in 2011, updated and signed again in 2013, and remaining in force now; and the Corps' Engineering and Construction Bulletin 2018-14, Guidance for Incorporating Climate Change Impacts to Inland Hydrology in Civil Works Studies, Designs, and Projects. The numerical-model simulated outputs were evaluated by multiple technical means (see record of the full Corps Agency Technical Review), and were tested using the set of analytical measures created by the Corps' Climate Preparedness and Resilience program to ensure sound science and engineering compliance with the Corps' USACE climate change policy and guidance. Those analytical tests are described in ECB 2018-14 (listed just above) and in the Corps' Engineer Technical Letter 1100-2-3, Guidance for Detection of Nonstationarities in Annual Maximum Discharges. The assessment of climate threats and impacts is qualitative only in the sense that the biological and other impacts models did not directly ingest the physical hydroclimatology outputs modeled for the assessment. Those hydroclimatology outputs are fully quantitative and so can be the basis for refined estimates of effects and impacts should those be required following this Draft EIS.
3139	2	taermak@yahoo.com	N/A	Before you actually start destroying something you need to create replacement for it. Energy Northwest only have 15 years left- is there a plan to extend its services or are you planning to build a new nuclear power plan?	For each alternative that reduced hydropower generation and regional power reliability, the EIS analysis estimated the amount of replacement power generation required. The potential replacement of Columbia Generating Station, was beyond the scope of the EIS.
3153	2	N/A	N/A	Just build a long bypass river around each dam.	The Draft EIS analyzed several ways to bypass juvenile fish around Columbia River System dams, from dam breach to surface bypass and spill. These are similar to "building a river around the dam" as the comment suggests, but also meet the biological criteria utilized after decades of research and development of fish passage at these dams.
3155	1	kkinzer@moscow.com	N/A	I have talked with many of the fisheries biologist involved with doing these studies over the last 30 years. They know we can, and have found ways to make fish and dams work together. The one thing they have not been able to get a handle on, is the food supply in the ocean for the salmon. This is the 800 pound gorilla in the room. It makes no sense to remove 4 of the 8 dams between the salmon river and the ocean, if the fish get the ocean and die of starvation. We need to quit spending time and money on the dams, because they need to stay. We need to address the real problem. This problem has been known since the 1990's when Canada commissioned a study, that showed this problem. Basically the study found out that each run from different areas of the same river went to different spots in the ocean to rear themselves. The return of each run was dependent on how much food was available in that area of the ocean. We have rivers up and down the west coast of America and Canada that do not have one single dam, and have experienced low returns. In fact the lower Columbia Coho run, that doesn't go through one dam, basically went extinct back in the late 1990's. We know the problem, lets address it.	There are many effects to salmon and steelhead populations outside the operation and maintenance of the dams (see Chapters 6 and 7 for more information). Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. While none of the Multiple Objective alternatives would affect ocean conditions, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of this environment in the return of adult salmon and steelhead (Peterson et al. 2019). As such, two of the models used in these analyses, National Marine Fisheries Service (NMFS) COMPASS and CSS Lifecycle Models, use metrics of ocean productivity to predict adult returns. These metrics can be seen at: https://www.nwfsc.noaa.gov/research/divisions/fe/estuarine/oeip/g-forecast.cfm. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm.
3159	2	lherburger@hotmail.com	N/A	The habitat improvement for salmon and the follow-on impact for Southern Resident killer whales needs to be more heavily weighted in consideration of the environmental impact of these dams.	The alternatives analyzed in the EIS include operational or structural measures at the 14 projects sites. Where adverse effects to habitat are anticipated as a result of implementing an alternative, habitat restoration was proposed. For instance, the Preferred Alternative added habitat mitigation along wetlands and riparian areas in the John Day reservoir and around Lake Roosevelt. The Preferred Alternative also carries forward certain ongoing actions including habitat measures that are described in Section 7.6.4.1 with examples listed in Table 7-5 in the Draft EIS. The purpose of the EIS was to evaluate alternative ways to manage the 14 federal projects and determine if a new operation or configuration of the projects could reduce adverse impacts of the system operations, meet the EIS Purpose and Need Statement, objectives, and meet all regulatory and statutory compliance requirements. The Preferred Alternative carries forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has minor effects on Southern Resident killer whales as described in Section 7.7.8.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
3161	2	drcadwallader12@gmail.com	N/A	Recreation improved with dams on lower Snake? Baloney! On any given weekend all summer long 10 times more boats and people utilizing the beaches and free flowing stretch of the Snake River above Asotin that on all of Lower Granite Pool. Free flowing river all the way to Tri-cities will enhance boating related recreation. Furthermore , because of warm water in the Snake River,Dworshak Reservoir is drawn down quickly annually each fourth of July resulting in a substantial decline in boat use due to the long mud slopes and unusable boat access camping spots. This drawdown would cease with a free flowing lower Snake and provide a big boost to local economies.	The potential benefits to recreation associated with MO3, which includes breaching the four lower Snake River dams, is described in Section 3.11.3.5. The EIS describes the potential for increased river recreation such as boating, rafting, and kayaking under MO3. There is some uncertainty in the figures; non-fishing recreation in the lower Snake River reach could range from 1.2 to 3.4 million visitors per year. Dworshak's summer drawdown would remain the same under MO3 as under the No Action Alternative because the cooling water in the lower Snake is needed under both alternatives.
3161	3	drcadwallader12@gmail.com	N/A	Predators: virtually ALL predatory activity on smolts and adult fish is greatly enhanced if not totally due to the 4 dams. Warm water predatory fish thrive because of the warmer slow moving water to include Pike Minnows, bass, walleye. Terns, cormorants, sea lions and seals all make use of the dams and slow moving water to inflict their collective damage.	The co-lead agencies disagree with the suggestion in the comment that all predatory actions on fish are a result of the existence of the dams. However, ongoing actions described in the No Action Alternative to reduce predation on migrating fish are included in the Preferred Alternative. In addition, water management actions (the Predator Disruption Operations measure) in the John Day reservoir is expected to further reduce avian predation on migrating juvenile fish. The No Action Alternative includes ongoing mitigation measures to haze and monitor pinniped predators. These actions would continue into the future under the Preferred Alternative, and the co-lead agencies would continue to assist National Marine Fisheries Service (NMFS), states and Tribes in their pinniped removal efforts near Bonneville Dam. The co-lead agencies currently implement a Northern Pikeminnow Management Program which includes an ongoing base program and general increase in northern pikeminnow sport-reward fishery reward structure to reduce predation by these fish. This measure would continue under the Preferred Alternative. Management of gamefish such as walleye typically falls within the authority of state fish and wildlife agencies.
3163	2	news4punky@gmail.com	N/A	Would blackouts from less electricity become the norm? How would the loss of dam-produced electricity be made up?	The EIS finds that under all of the Multiple Objective alternatives (MOs) except the Preferred Alternative and Multiple Objective alternative 2 (MO2), power system reliability would decrease, increasing the likelihood of outages. Table 2-1 in Appendix H of the Draft EIS presents the likelihood of blackouts by alternative and Chapter 2 of Appendix G describes how reliability could be returned to No Action Alternative levels with replacement resources. Section 3.7 of the Draft EIS also describes the replacement resource portfolios and associated costs for maintaining regional reliability at the No Action Alternative level.
3171	1	N/A	N/A	It is important to note that it is not just people living in flood prone areas that have a need for flood control. There are beneficial uses of that land that all citizens enjoy. Transportation through flood areas, jobs and products that sustain and save lives are produced in these areas. The use and benefit should not be portrayed as "just a few people living where they shouldn't".	As described in Section 2.2, Overview of Alternatives Development Process, the flood risk analysis completed for the EIS, and described in Section 3.9 Flood Risk Management, assessed flood risk for communities, property, and resources throughout the Columbia River Basin. The analysis evaluated flows and stages, both downstream of reservoirs and in reservoir pools, for the No Action Alternative, Multiple Objective alternatives (MOs), and Preferred Alternative. For reporting results, the analysis utilized sample National Weather Service gage locations throughout the Basin. The gage locations are commonly utilized reporting locations, used to assess and communicate flood risk levels for developed and undeveloped reaches throughout the Basin. The findings in the EIS for implementing the Preferred Alternative are that there would not be an increased risk of flooding to any communities in the Columbia River Basin.
3174	1	spauley4@gmail.com	N/A	www.rand.org/.../monograph_reports/2002/MR1604.pdf Pllease revisit this Rand Report of 2002 It;'s still valid today. Breaching will create 25,000 jobs and will not harm the economy of the Northwest. The powers at the time ignored this report. It's not what they wanted. PLEASE re visit this report.	The EIS acknowledges previous analyses conducted in the 2002 LSR Study. However, the CRSO EIS relies on high-quality and scientifically accurate information to evaluate the effects associated with breaching the four lower Snake River dams under MO3. The EIS analysis includes the current conditions in the basin as of initiating the EIS in 2016 and those actions that will continue as of September 2016. It then compares the Multiple Objective alternatives to the No Action Alternative.
3175	1	spauley4@gmail.com	N/A	One study, the Rand Report 2002, never received the attention it deserved. It was ignored and then disappeared from the web then reappeared. www.rand.org/.../monograph_reports/2002/MR1604.pd Rand is a conservative think tank and should be taken seriously. It never was. Rand concluded that breaching the 4 Snake dams would not harm the economy and would create 25,000 new jobs. Power needs could be handled with combined cycle natural gas plants, conservation, and wind and solar. (Now solar has taken over in a big way in the NW.) More dam tweaks, spill, hatchery fish won't do the job to restore our native salmon and steelhead. The dams must go. www.rand.org/.../monograph_reports/2002/MR1604.pd	The EIS acknowledges previous analyses of breaching the four lower Snake River dams. However, the EIS relies on high-quality information to evaluate the effects associated with the Breach Snake Embankments measure under MO3. Please see Section 3.7.3.5, Social and Economic Effects of Changes in Power and Transmission, for a discussion of the regional retail rate effects of breaching the four lower Snake River dams. As described in that section, the impacts under MO3 include increased electricity rates for most consumers of energy in the region, which has the potential to have the highest impact on rural areas. Higher retail rates means less spending on production, which affects employment. See Draft EIS Table 3-175 for the regional economic effects from changes in household spending on electricity.
3187	1	jonchris@skadden.com	N/A	While much attention has been put on the discussion of dam breaching, not enough has been placed on the costs of such action and utilizing modern methods of addressing the salmon declines. I believe that salmon and dams can co-exist, but with a more sophisticated discussion than has occurred to date.	The costs of dam breaching are described in Section 3.19.2 and in Appendix Q. MO3 would result in decreased costs or funding requirements for the lower Snake River projects compared to the No Action Alternative, including capital costs, operations and maintenance, non-routine navigation, non-routine extraordinary costs, and fish and wildlife mitigation costs. However, dam breaching would also result in construction costs and costs for additional mitigation measures to address the adverse effects of MO3 consistent with information presented in Section 3.19. Based on the fish in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.
3188	1	Wiskyjack@hotmail.com	N/A	Lets focus on increased production. Let the tribes pay for ladders over Chief Joe, Grand Coulee, Dworshak and others. It will help offset the taxes they dont pay on casino earnings. Bring in some 100 pound fish from AK, and lets rebuild the June Hog fishery in the Columbia. Let the Tribes do more resevoirs on the Snake that model after Cold Springs resevoir on the Umatilla. Those fish made an immediate improvement.	The scope of the CRSO EIS covered eight objectives of which salmon, steelhead, and resident fish were three. In particular, the co-lead agencies developed measures to improve fish passage and fish flows, and reduce adverse impacts to spawning habitat. Fish harvest is the responsibility of NMFS and USFWS and continues to be researched by these agencies. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and Tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so. The agencies did look at increased production but determined it would only be needed if MO3 were to be implemented for short-term impacts. Moreover, measures to reintroduce salmon above Grand Coulee and Chief Joseph were evaluated early in the alternative development process but eliminated from further consideration. Reintroduction is an important and complex, large-scale concept. Its consideration, evaluation, and implementation should involve multiple tribal, federal, state, and other entities. A coordinated approach among water users, tribes, states, multiple federal agencies, and others would be necessary. To allow so many differing interests to coordinate on such a complex topic, which may include international considerations, a decision-making framework and a series of regional workshops would be necessary just to approach the first step of defining reintroduction objectives. Given the incompatibility of such a wildlife management decision-making framework with an analysis of the operation of the CRS, it is not feasible to proceed with a detailed consideration of reintroduction in this EIS. Moreover, to meaningfully analyze reintroduction as a measure, the details of the proposal would need to be understood well enough to include in hydrologic, water quality, and fish models. That information is not presently available, and development of those details was not possible in the timeframe of this NEPA process. Nevertheless, the agencies and interested regional sovereigns are developing a framework to address critical information gaps.
3188	2	Wiskyjack@hotmail.com	N/A	As long as runs will support commercial, tribal, sport, and other nations harvesting these fish, there should not be a problem. Lets focus on increased production. Let the tribes pay for ladders over Chief Joe, Grand Coulee, Dworshak and others. It will help offset the taxes they dont pay on casino earnings. Bring in some 100 pound fish from AK, and lets rebuild the June Hog fishery in the Columbia. Let the Tribes do more resevoirs on the Snake that model after Cold Springs resevoir on the Umatilla. 3190	1	jntmyers@gmail.com	N/A	This entire process has been flawed from the beginning. Information on the anadromous fish mortality caused by reservoirs behind dams was not presented to the public. There were no public meetings in Idaho in the many rural areas affected by the continued loss of salmon and steelhead.	The effects to anadromous fish from each alternative including the No Action Alternative are presented in Section 3.5 and for the Preferred Alternative, the effects to anadromous fish are shown in Section 7.7.4. To ensure adequate opportunity for the public to provide comments on the Draft EIS, the agencies hosted an online comment platform, provided mailing addresses for written comments, and hosted a series of public comment meetings by telephone. Hosting the public meetings by telephone allowed interested stakeholders in areas where an in-person public meeting was not originally scheduled to participate in the meetings. The co-lead agencies offered these public comment meetings by telephone to maintain our commitment to accepting verbal comments in accordance with current public health guidelines. As these meetings provided similar accessibility for providing and listening to verbal comments in a public hearing format, the agencies did not postpone the public comment meetings.
3191	1	pixelate@mathsavers.com	N/A	I phoned in to the Comment Teleconference on Tuesday March 31, 2020 at 3:45pm and followed the instructions to enter the queue for speaking. After 4 hours, and an additional 50 minutes, I was not contacted. I can only assume that there were technical difficulties.	We are sorry you had technical difficulties. The public was also able to provide comments using the online form or through mail. We are glad to see you were able to provide comments.
3197	3	N/A	N/A	This Draft EIS is a poor compromise in that it doesn't adequately address the plight of Columbia River anadromous fish. The agency authors and their contractors are setting the stage for the final solution to these fish, extinction by choice. It is so obviously apparent that the solution for fish is in direct conflict with the status quo. Keep the four lower Snake Dams in place, tinker with the fish biology, and let taxpayers pay for the bill; a BPA/COE induced trend that has gone on for 30 years. This document will be historic record of how a nation and northwest politicians decided on the extinction of salmon; a commendable and rewarding legacy for them but not for the fish. Why did they do this? How could they have done this? Future generations of northwest people will ask? There is one more opportunity for US to change this course of extinction. Revised the final EIS and fully address the merits of removing the four lower Snake River Dams. Then make it the preferred decision.	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets the EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies used high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult (SAR) return rates will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council's (Council's) recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Finally, the co-lead agencies disagree the Preferred Alternative is a slight deviation from previous operations. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The Preferred Alternative also includes other operational, structural and mitigation measures to improve conditions for ESA-listed salmon and steelhead.
3200	1	jameswarren58@hotmail.com	N/A	Noreen Clough, B.A.S.S. national conservation director, spoke against removing bass restrictions on the Columbia River. By Noreen Clough May 24, 2013 Noreen Clough, B.A.S.S. national conservation director, presented the following speech at an American Fisheries Society conference in Boise, Idaho, April 16. A condensed version was published in the June issue of B.A.S.S. Times.	The co-lead agencies are uncertain as to what the comment is suggesting in relation to the Draft EIS and unable to provide further response.
3202	1	N/A	N/A	You may add me to the burgeoning list of other scientists who have strongly urged removal of the four lowermost Snake River dams. The multitude of sound reasons for removal are outlined in the recently released CRSO EIS draft. Yet the draft was prepared, and the preferred option chosen, by the same two federal agencies, The Corps of Engineers and Bureau of Reclamation, who have jointly wracked the greatest ever man-caused damage to Columbia Basin anadromous fish runs. This latest EIS process is thus illogical, perhaps illegal, and its chosen option no surprise.	The CRSO EIS documents the assessment of benefits and impacts of changes to the operations of the 14 Federal projects of the Columbia River System. Using a multi-disciplinary approach and with the coordination and consideration of our cooperating agencies and Tribes, as well as public stakeholder input, and by using the current, high quality information, the co-lead agencies developed the Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative will make a meaningful contribution towards recovery.
3208	1	swzuger@lctinc.biz	N/A	The "first step for fish" comes with the cleaning up of Puget Sound. It is beyond belief the way the people of the surrounding cities have allowed this beautiful body of water to be miss treated. Lets start this cleanup with greater sewage plant capacity, and get our Canadian Neighbors to do their share with their sewage as well! I have a great deal of respect for all of our natural resources and believe that improving fish runs is very necessary. The endangered species act needs to be applied to real life, specifically situation by situation, not one size fits all. The current honey-hole that has been created for sea lions between Astoria, WA and Bonneville Dam is an example of this. The current situation where there are way too many sea lions in that section of river is decimating fish runs unnecessarily. The "second step for fish" is to get this sea lion population under control. Trap them, move them, allow Native Americans hunting of them, or allow Fish and Wildlife Agents to hunt them .Then send the meat to the homeless shelters we have in Oregon and Washington, so that the true population of sea lions is normal to that section of river. The "third step for fish" is to do something similar to control birds who prey on fish smolts. We have created abnormal feeding opportunities and these birds have been taking a toll. The Lewiston - Clarkston Valley is not a normal place to find pelicans, yet they come here now to prey on the juvenal steelhead and other fish available in the spring and summer. Since the Pelicans are protected they have free run, yet some hunting pressure would help send them away.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Regarding Puget Sound, the effects mentioned in the comment involve a variety of issues beyond the scope of the CRS project. However, water quality effects for the Columbia River Basin were considered in the EIS analysis and are described in Chapter 1, 2, and Section 7.8.3 of the EIS. Additionally, the U.S. Army Corps of Engineers is in partnership with other Federal, state and non-governmental organizations and have been implementing habitat projects for salmon, orcas, and wildlife all around the Puget Sound as part of the Puget Sound Nearshore Ecosystem Restoration Project.
3211	1	N/A	N/A	One option, MO3, should be rejected under all scenarios. This option calls for the removal of the four lowest dams on the Snake River, ostensibly to improve salmon and steelhead passage. But these dams all have fish ladders that do allow adult fish passage to restricted natal spawning areas. If dam removal is still being considered, then there are four other dams that should be removed first. Those dams are Dworshak Dam on the Clearwater River and Hells Canyon, Oxbow and Brownlee dams on the Snake River. None of these dams even have fish ladders, completely blocking all spawning grounds upstream from access. Any dam removal will reduce the hydropower production that reduces the carbon footprint, but the cost/benefit ratio it much lower for those dams that block all fish passage.	As indicated, the lower Snake dams in the CRS all have fish passage. Breaching the embankment of the four dams is thought to improve fish migration time for the Snake River species that migrate this river. Removing or providing passage to the other projects listed in your comment to allow access to these migrating fish to spawning grounds are outside the scope of this EIS. The Preferred Alternative does not include breaching the four lower Snake River dams.
3217	1	Katie Bilodeau	Friends of the Clearwater	We were disappointed that you chose not to extend this comment period, especially for such a large environmental impact statement and in light of an ongoing pandemic.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website notified the public on April 9, that they should plan to submit comments by the close of the comment period.
3217	2	Katie Bilodeau	Friends of the Clearwater	The science we have provided pursuant with the discussion below is the best available science. If any agency is relying on other science, we request an explanation as to why the agency is relying on the other science instead of what we have provided.	The co-lead agencies used the most current, high-quality and scientifically accurate information, a multi-disciplinary team, and a science-based approach to analyze the alternatives in the EIS. Federally-funded hatcheries in the Columbia River Basin are adaptively managed to minimize impacts on wild fish. The regulatory and co-lead agencies use the best available science to establish best management practices for these programs. The co-lead agencies fund many ongoing research projects to better understand and minimize hatchery and wild fish interactions (i.e. evaluating the relative reproductive success of hatchery fish spawning in the wild from both segregated and integrated stocks, monitoring stray rates of hatchery and wild fish, understanding mechanisms that produce precocious maturation of male hatchery fish), including several referenced in your letter; however, information specifically focused on artificial propagation, while relevant to individual hatchery EISs and BiOps, is out of scope for the CRSO EIS.
3217	3	Katie Bilodeau	Friends of the Clearwater	The Clearwater Basin of North-central Idaho is the northern half of the Big Wild, which is the largest undeveloped watershed complex left in the Lower 48. It is also the southern boundary of the largest known inland temperate rainforest in the world. The Nez Perce and Clearwater National Forests make up a good portion of the Clearwater Basin, and our mission area is home to spawning and breeding grounds of rare and imperiled species that include bull trout, salmon, and steelhead. Because these fish are born and migrate back to our mission area, we are uniquely situated to discuss some of the cumulative effects that we dont think the draft EIS for the Columbia River System Operations has properly considered. Particularly, we noticed a couple of instances where the agency assumes that actions are mitigation impacts when, based on the best available information and defining mitigation as actions that ease injury to a fish species, these actions are more properly categorized as adverse cumulative impacts. NEPA-implementing regulations define mitigation as including: (a) Avoiding the impact altogether by not taking a certain action or parts of an action. (b) Minimizing impacts by limiting the degree or magnitude of the action and its implementation. (c) Rectifying the impact by repairing, rehabilitating, or restoring the affected environment. (d) Reducing or eliminating the impact over time by preservation and maintenance operations during the life of the action. (e) Compensating for the impact by replacing or providing substitute resources or environments. 40 C.F.R. 1508.20. And these regulations define cumulative impact in the following way: Cumulative impact is the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (Federal or non-Federal) or person undertakes such other actions. Cumulative impacts can result from individually minor but collectively significant actions taking place over a period of time. 40 C.F.R. 1508.7. Whether hatcheries are short-term mitigation or adverse long-term impacts depend upon how we define the injury. Hatcheries impose adverse cumulative effects on the existence of wild fish populations. Some habitat programs, funded by the Northwest Power Act, are also probably and inadvertently propping up increased logging levels. The agency needs to discuss this and assess the impacts of business-as-usual, especially since the funding meant to mitigate for salmon and steelhead is actually funding negative cumulative impacts to salmonids from hatcheries and habitat. CUMULATIVE IMPACTS NFMS recognizes the following factors as those that limit the recovery of wild salmonids: * Mainstem Columbia River hydropower-related adverse effects, * Impaired tributary fish passage, * Degraded, including degradation in floodplain connectivity and function, channel structure and complexity, riparian areas and large woody debris recruitment, stream flow, and water quality as a result of cumulative impacts of agriculture, forestry, and development, * Impaired water quality and increased water temperature, * Related harvest effects, particularly for B-Index steelhead, * Predation, and * Genetic diversity effects from out-of-population hatchery releases NMFS 2018 Biological Opinion and EFH Consultation FEIS, p. 146. Our government has done a fantastic job in isolating these impacts and discussing them in different EIS vacuums where the responsible agency can just minimally gloss over the other environmental impacts. Salmon and steelhead face four main threats: hydropower, harvest, hatcheries, and habitat, and they all add up. The existence of harvest depends upon hatcheries, and vice versa. The combination of the above factors is driving our wild salmonids towards extinction, and unless the government takes an action that can make the biggest change, like breaching the lower four Snake River dams, all of these cumulative impacts will press wild salmonids out of existence. Because this pressure is increasing from all sides in terms of cumulative impacts, the cumulative impacts discussion in this draft EIS is woefully insufficient. We elaborate below. Hatcheries hurt wild fish populations Hatcheries and their adverse impacts on salmon and steelhead deserve a weight and discussion that the USACE has not adequately considered. In Chapter 5, the agency cites Bonnevilles Lower Snake River Compensation Plan and the hatcheries that are funded as mitigation. In Chapter 6 (p. 2) the EIS again calls hatcheries positive and offsetting to negative impacts. In the most simplistic narrative, hatcheries replace numbers of fish lost for human consumption. However, hatcheries impose negative ecological and genetic impacts that are becoming more widely understood than when salmon and steelhead were listed and the National Marine Fisheries Service implemented regulations that allow for hatcheries. See 50 C.F.R. 223.203. In the past fifteen years, more science has emerged about the negative impacts of hatcheries. In conjunction with dams, hatcheries are suppressing the ability of salmon and steelhead to recover at best, and may be driving wild salmonids towards extinction at worst. For the below reasons, hatcheries are negative cumulative effects for wild fish, and the draft EIS must acknowledge and discuss this. Weve provided the best available science on this subject in addition to other agencies NEPA documents that recognize the negative impacts of hatcheries. Large releases of hatchery fish increase ecological risk factors. Several studies have specifically implicated large numbers or high proportions of hatchery fish as contributing to a decrease in wild fish productivity, abundance, or survival. Kostow 2009. Kostow discusses a historical example of what the cumulative effects of large-scale hatchery programs, habitat	Hatchery programs have long been a part of the approach for salmon recovery. Figure 3-111 in the Draft EIS is an illustration that the CRS can and has supported large numbers of returning adult salmon and steelhead. As noted, this figure combines hatchery and wild fish. The commenter is correct -- there are broad ecological effects concerning interactions of wild and hatchery fish, as well as harvest, throughout the basin. However, the actual mechanisms, effects, magnitudes, and processes are very complex and uncertain. The analyses used in the CRSO EIS were for the purposes of comparing the effects of the Multiple Objective alternatives for operation and configuration of the CRS projects to the No Action Alternative. Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the NOAA 2018 EIS and reflect current harvest management guidelines. To see their conclusions and effects analyses please go to: https://www.fisheries.noaa.gov/resource/document/environmental-impact-statement-programmatic-review-harvest-actions-salmon-and. Hatchery origin fish are very important to Tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act. These consultations ensure the hatchery programs are not appreciably reducing the likelihood of ESA-listed species survival and recovery, or adversely modifying or destroying designated critical habitat. These consultations have resulted in many site-specific reforms to reduce effects of hatchery/wild fish interactions, such as decreasing the temporal and spatial overlap of wild and hatchery fish in integrated programs or transitioning to local broodstock in integrated programs, similar to the examples cited in the comment. The co-lead agencies used the most current, high-quality and scientifically accurate information, a multi-disciplinary team, and a science-based approach to analyze the alternatives in the EIS analysis. Federally funded hatcheries in the Columbia River basin are adaptively managed to minimize impacts on wild fish and the regulatory and action agencies use the best available science to establish best management practices for these programs. The co-lead agencies fund many ongoing research projects to better understand and minimize hatchery and wild fish interactions (i.e. evaluating the relative reproductive success of hatchery fish spawning in the wild from both segregated and integrated stocks, monitoring stray rates of hatchery and wild fish, understanding mechanisms that produce precocious maturation of male hatchery fish), including several referenced in your letter; however, information specifically focused on artificial propagation, while relevant to individual hatchery EISs and BiOps, is out of scope for the CRSO EIS. Consultations under Section 10 of the ESA also ensure that programs intended to be integrated recovery programs do indeed contribute to ESA-listed species. It is appropriate to claim beneficial effects from these hatchery programs. Based on the anadromous fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Under the Preferred Alternative, hatchery and habitat programs would continue as under the No Action Alternative, and a number of other mitigation measures would continue as well, but no new hatchery programs are proposed. The Preferred Alternative proposes measures such as increased spill intended to improve survival of juvenile anadromous salmonids. Over time, the Preferred Alternative is anticipated to benefit both wild and hatchery fish. Regarding dam breach, overall the conclusion in the Draft EIS is that MO3 would be beneficial to anadromous fish. The effects to populations as they transition from primarily hatchery production to an increased wild production of fish is qualitatively discussed in Section 3.5.3.6 in the Draft EIS. The co-lead agencies recognize the value of long-term benefits compared to short-term impacts as described in the Draft EIS. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as the MO3 which includes the dam breaching measure. The Preferred Alternative also meets the EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				loss and degradation, and high harvest rates can wreak, using the Columbia River Basin: A specific example of this pattern is the lower Columbia River, which historically produced abundant wild Chinook, coho and chum salmon and steelhead. Extensive releases of hatchery fish, particularly of Chinook and coho, occurred throughout the twentieth century. By the early 1990s, Oregon Department of Fish and Wildlife (ODFW) was releasing about 2835 million fall Chinook, 89 million spring Chinook and 11 million coho annually into the lower Columbia and its major tributary the Willamette River (Kostow 1995). Washington was releasing additional Chinook and Coho salmon in the same area. These releases produced tens of thousands of adult hatchery fish that supported high harvest rates (Wright 1993; Flagg et al. 1995; Good et al. 2005). The hatchery fish that escaped the harvest returned to natural production areas in the lower Columbia River basin that by the 1990s contained no more than a few hundred adult wild fish (Wright 1993, Kostow 1997). By the early 2000s, many wild Chinook and coho salmon populations in the lower Columbia were considered to be extirpated (Good et al. 2005) and the remaining wild fish were listed under the ESA, along with the steelhead and chum populations in the same geographic area. Although the specific mechanisms of hatcherywild fish interactions were not assessed, the large numbers of hatchery fish released and the high harvest rates in fisheries targeting the hatchery fish were among the factors found to contribute to the poor status of these populations in the reviews leading to the final ESA listing decisions (Flagg et al. 1995; Weitkamp et al. 1995; Myers et al. 1998; Good et al. 2005). Kostow 2009. Large hatchery releases negatively impact wild fish survival. The group size of hatchery fish, whose individuals do not disperse as far as wild fish, attract predators. The group-size attraction, compounded with exhibiting behavior not typical of wild fish (aggressive displays, surface feeding, and failure to seek cover), increase predation risks: Wild fish are typically intermingled among the hatchery fish, and so are also consumed at higher than natural rates when the hatchery fish are present and attracting predators (Collis et al. 1995; Nickleson 2003). Kostow 2009. Hatchery fish pressure the environments carrying capacity, and highly inflated numbers of hatchery fish will cause density-dependent fish mortality not typically experienced in natural populations. This means that, for more than one offspring to replace a parent, and for populations to recover from events that might lower abundance, the density of parents, eggs, and juveniles, in the environment must be relatively low. Kostow 2009. In addition to ecological impacts, hatchery-reared fish commonly exert negative genetic effects on wild populations, including lower survival and reproductive fitness. Araki et al. 2010. Numerically rare wild fish will mate with the abundance of fish from hatcheries, and the offspring are genetically predisposed to have low fitness in a wild setting. Studies on segregated broodstocks with a nonlocal origin indicate very low relative fitness[1] of the hatchery fish. Araki et al. 2008. A summary of these studies points to a fishs genetic makeup as a reason why. Scientists think that the mechanism that most likely explains fitness decline is selection imposed by domestication: Domestication selection has long been known to be a strong evolutionary force intentionally changing the characteristics of captive-reared organisms, and unintentional selection is likely to occur in typical supplementation programs as well. Araki et al. 2008. One study has confirmed this, finding that some of the genetics selected for captivity are severely maladaptive in wild environments, and resulting fitness decline in succeeding generations can be rapid. Christie et al. 2016. Researchers studying the genetic effects of domestication have found that hatcheries produce fish that are genetically predisposed to have low fitness in natural stream environments. This lower fitness arises after only a few generations of domestication selection, leading researchers to suggest repeated use of captive-reared parents to supplement wild populations should be carefully reconsidered. Araki et al 2007. This study was repeated in 2016 by NOAA scientists with similar results. Ford et al.2016. Lower relative fitness from hatchery fish carries over to their wild-born descendants, thus impacting wild fish populations. In a study published by Araki et al, researchers reconstructed a genetic pedigree on steelhead trout and estimated reproductive fitness of wild-born descendants. In comparison to fish with two wild-born parents, wild-born fish with a single hatchery parent have a relative fitness of 87%, while wild-born fish with two hatchery parents have a very low relative fitness of 37%. Araki et al. 2009. These data are relevant to the long-term success of wild-born salmon. This is particularly concerning when it is clear that more hatchery-born fish are added every year into these systems. The fitness of wild-born fish appears to be in danger, and there is a distinct possibility of extinction that needs to be explicitly considered, and needs to be considered in a way that incorporates the reduction in genetic diversity since the beginning of segregated hatchery programs. The cumulative effects of this over generations could absolutely become significant and are amplified in a dwindling wild fish population. Steelhead provide a good illustration of hatcheries negative impacts. Idaho steelhead hatcheries are not for the recovery of wild fishthey exist to provide the only sport fishing and harvest opportunity available for steelhead. NMFS 2019 EA pp. 9, 13-14 (pdf pp. 26, 30). The Idaho-operated steelhead hatchery fish are genetically isolated from the wild steelhead. NFMS 2017 p. 2. NMFS defines integrated hatchery programs as those that are reproductively connected or integrated with a natural population, promote natural selection over hatchery- influenced selection, contain genetic resources that represent the ecological and genetic diversity of a species, and are included in a salmon ESU or steelhead DPS. When a hatchery program actively maintains distinctions or promotes differentiation between hatchery fish and fish from a native population, then NMFS refers to the program as isolated (also referred to as segregated). Isolated programs promote domestication or selection in the hatchery over selection in the wild and may culture a stock of fish with phenotypes (e.g., different ocean migrations and spatial and temporal spawning distribution) different from the natural population. NMFS 2017, p. 1. As discussed above, maintaining a hatchery population that is intentionally distinct from a wild population will not contribute towards conservation of the wild populationthe hatchery population introduces a risk of cross-breeding, which will reduce the genetic fitness of the wild population. See McClure et al. 2008,2 Weigel et al. 2019. The numbers of steelhead passing Lower Granite Dam are at an all-time low. See Fish Passage Center Lower Granite dam adult counts. The wild-born and the wild-born B-run are even smaller fractions of those numbers. Hatchery programs like the South Fork Clearwater program are not designed for conservation of wild fish and have no conservation benefit. When hatchery fish arent caught, these hatcheries are providing adverse genetic consequences pulling steelhead towards an extinction vortex by adding domesticated genes into the wild fish population. Even accepting the premise that the non-local broodstock for steelhead has genetic remains from the extirpated North Fork Clearwater steelhead population, it has also had generations of domestication selection at the hands of humansthis genetic line has been repeatedly propagated and reared at Dworshak before released as juveniles. For this reason, even for some broodstock that might have a minor genetic legacy of its ancestry (the extent of which has only ever been discussed anecdotally) from a neighboring basin, artifacts of domestication selection cannot be ignored. In the last ESA status review for steelhead, the Northwest Fisheries Science Center updated risk assessments for major population groups of steelhead in Clearwater River (Major Population Group). The Center renewed the Lower Clearwater steelhead population at a moderate risk for abundance and productivity. The Center issued a high risk rating on abundance and productivity for Lolo Creek and South Fork Clearwater, where [t]here are relatively large and consistent hatchery releases into the area. Northwest Fisheries Science Center (NFSC 2015). The Center stated, The PBT results for the initial year of adult hatchery returns (2012) indicate substantial numbers of hatchery fish are available to spawn after accounting for known removals. It is not possible at this time to generate productivity estimates for this grouping since estimates of the total number of spawners including hatchery fish are not available. For this review, the provisional high-risk A/P ratings applied in prior reviews will be carried forward. NFSC 2015 p. 116. In Idahos Final Steelhead Hatcheries Proposed Evaluation Pending Determination (PEPD), the authors admitted that interbreeding and competition with hatchery fish that outnumber natural-origin fish are one of the reasons that Snake River Steelhead DPS remain threatened, and that [h]atchery effects are likely more pronounced when the program occurs on a listed population. Idaho Steelhead Proposed Evaluation Pending Determination, p. 6. Then the PEPD listed various streams where the fraction of hatchery fish exceeded 50 percent: Tucannon, Asotin Creek, Lolo Creek, South Fork Clearwater, Little Salmon River, Pahsimeroi, Lemhi, East Fork Salmon, and Upper Salmon River. If a smaller fraction of hatchery fish could pose a significant effect, having the majority of fish in the area be the hatchery fish significantly compounds that. Continued plans for the release of hatchery fish will continue to compound the negative impacts of hydropower on threatened salmonids. The release of hatchery steelhead dramatically outnumbers wild B-run fish. And these two types of fish are not identical – hatchery steelhead are genetically divergent because of artificial selection, which causes offspring that survive poorly in natural stream environments. Christie et al. 2012. Hatchery fish that mate with wild fish will pass along the genetic divergence to their offspring. Specifically, hybrid offspring are much less fit than B steelhead born of two wild parents and raised in nature. Araki et al. 2009. Natural-born steelhead therefore face a one-two punch given their rarity: they will very likely mate with hatchery fish and then produce offspring that are poorly suited to survive. Based on the science of genetics and operation of hatcheries, hatcheries are negative cumulative impacts to wild fish. Hydropower contributes to this if hatcheries release numbers of fish based upon how many pass the dams on their return migration. The draft EIS must properly recognize and analyze hatcheries negative impacts to wild fish and how hatchery funding from cooperating agencies contribute to these cumulative impacts. If one looks at mitigation from the viewpoint of wild salmonids, hatcheries are not mitigation. Habitat mitigation is probably supporting increases in logging on the Nez Perce-Clearwater National Forests, which nullifies the mitigation efforts in these national forests We would like USACE and its partnering agencies, including the Bonneville Power Administration, to know that, while you are claiming the funds spent on restoring upstream habitat is making spawning grounds better, the U.S. Forest Service is relying upon some of this restoration to increase its logging levels, which undo any mitigative efforts. The Forest Service does not separate out its funding sources, which means that money funding salmonid-habitat improvement can be added into a pool where the Forest Service then uses that money to mitigate the adverse impacts of its own logging and roadbuilding projects. The clearest evidence to suggest this might	

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				be happening was in the Lolo Creek Watershed of the Nez Perce-Clearwater National Forests. The Forest Service has existing legal obligations under the National Forest Management Act to meet and comply with its forest plan. The applicable forest plan in this case, the Clearwater Forest Plan, has fishery habitat standards, including standards for Lolo Creek and its tributaries. Generally, if fishery habitat does not meet the requirements in the Clearwater Forest Plan for that stream, then the plan prohibits the Forest Service from approving activities (e.g., logging and roadbuilding) that would further degrade fish habitat because all management activities undertaken by the Forest Service must comply with the forest plan, which in turn must comply with the Forest Act, which requires that wildlife habitat must be managed to maintain viable populations of native and desired non-native wildlife species. Idaho Sporting Cong. Inc. v. Rittenhouse, 305 F.3d 957, 962 (9th Cir. 2002). Compliance with the Forest Plan is separate and distinct from BPA-funded restoration. The Northwest Power Act provides money to mitigate for hydropower losses. One of the express purposes of the Northwest Power Act is to protect, mitigate, and enhance the fish and wildlife, including related spawning grounds and habitat, of the Columbia River and its tributaries, particularly anadromous fish. 16 U.S.C. 839(6). To achieve this purpose, the Bonneville Power Association (BPA) developed a program to protect, mitigate, and enhance fish and wildlife in the Columbia River Basin, and the BPA is authorized to use the BPA funds to protect and enhance fish and wildlife to mitigate for the operation of dams in the Columbia River system. See 16 U.S.C. 839b(h)(1)(A), (h)(10). BPA funds are expressly to be used in addition to other existing legal obligations: Expenditures of the Administrator pursuant to this paragraph shall be in addition to, not in lieu of, other expenditures authorized or required from other entities under other agreements or provisions of law. 16 U.S.C. 839b(h)(10)(A) (emphasis added). So, the Forest Service is prohibited by law from using BPA funds to meet its own forest-plan obligations. Both the BPA and the Forest Service have reiterated that BPA funds should not be used to mitigate for Forest Service projects in a Memorandum of Understanding (MOU) for BPA-funded projects. But, the Forest Service does not keep BPA funds separate from other funds. In 2014 Friends of the Clearwater submitted a Freedom of Information Act request to the Nez Perce-Clearwater National Forests, asking how the agency differentiates between sediment-reduction activities done to mitigate Forest Service projects such as roadbuilding and timber sales and sediment-reduction activities funded by the BPA. We asked for guidance, policy, and accounting about how to differentiate these projects, in addition to a list of projects where both categories of restoration had taken place between 2009 and 2014. See FOC Watersheds FOIA 2014. The Forest Service responded that there existed no guidance on how to separate out sediment-reduction projects by funding mechanism, claiming that projects are generally not differentiated by funding mechanism during the NEPA stage. FS Watershed FOIA response.pdf (in BPA folder). The Forest Services lack of accounting of BPA money creates a situation where the Forest Service risks using BPA funds in order to offset the Forest Services own timber- harvest activities (mitigation activities such as decommissioning roads). And, based on some of what the Forest Service has reported back to the BPA, this might be happening. Two major recipients of BPA funding for habitat restoration on the Nez Perce and Clearwater National Forests are the Nez Perce Tribe and the Forest Service. The Nez Perce Tribe has invested a substantial amount of BPA money and work into restoring the Lolo Creek Watershed. According to the BPAs status report on the Lolo Creek Watershed, BPA has provided over two million dollars to the Tribe for restoration work specific to the Lolo Creek watershed. Completed as of 2018 includes culvert prioritization and assessment, installation of an offsite water source, twenty-eight culvert replacements, eleven culvert removals, 1600 ft. of stream bank stabilization, 16 miles of fence installation, and over 22,000 riparian trees planted. Additionally, the Tribe has decommissioned 101 miles of road in the Lolo Creek watershed as part of this restoration funding; the Tribe started restoration work in 2001 and it is ongoing. BPA 2018. This restoration work is why the existing fisheries habitat condition is better than it was. The Forest Service has also utilized a considerable amount of BPA funds to restore the Lolo Creek watershed. The same BPA report also shows that BPA has provided approximately $345,000 to the Forest Service for Lolo Creek Watershed Restoration. With this money, the Forest Service has also replaced culverts and has decommissioned over twenty miles of roads in the Lolo Creek Watershed. The Forest Services contract work began in 2007 and ended in 2010. In 2018, the Forest Service authorized a 3,387-acre logging project in the Lolo Creek watershed. This approved logging project included the construction of 15 miles of temporary road and a lot of other road work on the National Forest System Roads. USDA FS 2018; USDA FS 2018a. Even though the Forest Service generally claims that road decommissioning in its projects are not intended to offset timber harvest, decommissioning roads mitigate the logging projects and the road activities associated with them. This is because road decommissioning improves watersheds and timber harvest impairs watershed. When these two activities are combined and analyzed in one project, the benefits of the road decommissioning will offset the timber harvest. Substantively, this is also how the Forest Service defines mitigation: Measures designed to counteract environmental impacts or make impacts less severe. USDA FS 2018 FEIS p. 294. In the Lolo Insects and Disease Project, the Forest Service could not show that streams in the Lolo Creek watershed were meeting their beneficial uses absent BPA-funded mitigation. Records weve pieced together suggests that the Forest Service is using BPA funds to decommission roads that were intended to offset timber harvest impacts for previous logging projects in the Lolo Watershed area. For example, in the White/White Project (approved 2007), the Forest Service proposed over 2,300 acres of vegetative management, including regeneration cuts, commercial thinning, and pre-commercial thinning. See USDA FS 2007 p. 5. In White/White, the Forest Service intended to restore aquatic conditions for the express purpose of meeting forest plan conditions, among other things, and so proposed to construct and obliterate approximately 6.45 miles of temporary road for the timber sale and decommission approximately 16.2 miles of existing road, which amounts to 22.65 miles of road decommissioning and obliteration in total. USDA FS 2007 p. 5. In a completely separate report to the BPA for the time period 2007-2010, the Forest Service reports using BPA funding to decommission approximately 23 miles of road under the work-element titles, White-White Road Decommissioning and White-White II Road Decommissioning. BPA 2018 Status Report for Lolo Creek Watershed, p. 14. In order to demonstrate that the Forest Service had performed BPA-funded work in addition to, and not in lieu of, its own NFMA and forest-plan obligations for the White/White Project, the Forest Service would have had to show an accounting that it decommissioned approximately 45 miles of road in the White Creek watershed(s)22.65 miles of road decommissioning to offset impacts from timber harvest, and 23 miles of road decommissioning using BPA funds to offset the impacts from dams. Similarly, in the Yakus Creek timber sale (approved 2008), the Forest Service proposed 11.5 miles of road decommissioning, which would offset 450 acres of timber harvest and about 6 miles of road construction. USDA FS 2008 Yakus Creek Record of Decision, p. 1. The BPA report reflects the Forest Service reported to use BPA funds to decommission 10 miles of roads for Yakus Creek Road Decommissioning between 2007 and 2010. BPA 2014 Status Report for Lolo Creek Watershed, p. 14. In order to demonstrate that the Forest Service had performed BPA-funded work in addition to, and not in lieu of, its own NFMA and forest-plan obligations for the Yakus Creek timber sale, the Forest Service would have had to demonstrate approximately 21.5 miles of road decommissioning in Yakus Creek11.5 miles of road conditioning to offset timber harvest and an additional 10 miles funded by BPA to mitigate for dams. During the NEPA process for the Lolo Insect and Disease Project, Friends of the Clearwater raised this concern and asked for this accounting, but the Forest Service summarily dismissed this request, providing no information. The Forest Service refused to provide any accounting or details that could demonstrate or rebut FOCs concern that the BPA-funded restoration work in this watershed area was not the primary reason why the watersheds conditions were meeting forest-plan standards. See USDA FS 2018b Objection Response to FOC Lolo Insects and Disease Objection, p. 2. Without such an accounting and by refusing to provide one, there is a real possibility that the Forest Service is unlawfully spending BPA funds to meet its own forest plan obligations in order to approve future habitat-degrading activities, i.e. timber harvests and the road-building that accompanies them. There is also a real possibility that, for areas like the Lolo Creek watersheds existing condition (a result of BPA money and the Tribes excellent work), the Forest Service is relying on the improved existing condition to demonstrate that the area meets the minimum standards required by the Clearwater Forest Plan. Meeting the minimum forest-plan standards means the agency can approve more habitat-degrading logging and roadbuilding in the area. So, BPA funds are potentially mitigating for logging projects, and cant also be counted as mitigating for hydropower impacts. So long as the Forest Service isnt correcting this, USACE and BPA cannot count this as mitigation. What we have provided is just an example. This double-dippingthat the USACE and BPA are counting as habitat restoration to mitigate for dams while the Forest Service is counting the same habitat restoration to mitigate for its own habitat-degrading activitiesis relevant to the draft EIS analysis because it suggests that mitigation is having much less of an impact than assumed. To compound the problem that Northwest Power Act money might be mitigating for current timber harvests, upstream habitat may get much, much worse in the foreseeable future because of an upcoming forest-plan revision. The USACE must recognize and discuss this reasonably foreseeable negative cumulative impact. The Forest Service is revising the forest plans for the Nez Perce and Clearwater National Forestsdraft revised forest plan and EIS was released December 2019. Weve provided the 2014 Forest Service assessment on fisheries (Ch. 1) for the revised forest plan so NMFS can see what the current condition was in 2014. The upstream habitat for fisheries is still impaired in many places. USDA FS 2014. And this was with measurable, quantifiable standards. Whereas the 1987 Nez Perce Forest Plan and the 1987 Clearwater Forest Plan had measurable fisheries standards that related to cobble embeddedness, See USDA FS 1987a (Nez Perce Forest Plan Ch. II, p. 19 and Appendix A) and USDA FS 1987 (Clearwater Forest Plan, Ch. II p. 27, Appendix K), this new combined plan has no measurable standards for fisheries and the Forest Service has only proposed action alternatives that increase logging, one alternative up to four times the current levels. USDA FS 2019c p. 13. An increase in logging means an increase in roads, and an increase in roads means more fine	

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				sediment distributed to upstream habitat. If the Forest Service does not amend this trajectory, BPA money could not mitigate the Forest Services impact on salmon and steelhead habitat from logging activities, much less even come close to mitigating for the impact downstream dams have on fish. For these reasons, the funding going into upstream habitat projects, specifically in the Nez Perce- Clearwater National Forest, may not have the mitigative effects the USACE is relying upon to make up for the injuries to wild fish from hydropower. This needs to be properly disclosed to the public and discussed. Please choose the Multiple Objective Alternative 3: Breaching the Snake River Dams While we recognize that breaching dams is tricky with some potential short-term negative impacts, there is some great research from the Elwha Dam decommissioning about some species specifically the bull troutrapidly (and positively) responding to a post-dam environment. Brenkman et al. 2019. Please review itthe potential short-term issues with dam breaching is outweighed by incredible potential to recover wild salmonids and the long-term benefits of doing so. For the above reasons, wild salmonids are facing dire cumulative threats that, without drastic action, will keep them listed under the ESA in the best scenario, and will drive them into extinction in the probable scenario. Our organization and our members value wild species. What the agency and cooperating agencies presume to be mitigation is having nullified and even adverse cumulative impacts to wild fish in all alternatives. For these reasons, the best option to counter these impacts and preserve wild salmonids is with dam removal. While hatcheries, habitat, and harvest all need to be addressed, hydropower has the potential for the biggest impact by far.	
3220	2	handerson@cec-co.com	N/A	CEC remains concerned, however, about the wide variability around the two bodies of fishery science considered in the Draft EIS (i.e., NOAA's Life Cycle Model and The Fish Passage Center's Comparative Survival Study model). The extended operation at 125% Total Dissolved Gas ("TDG") at these federal projects called for in the Flexible Spill Agreement (and the basis for the PA) is an unprecedented action. We appreciate that the co-lead agencies understand the potential controversy arOLmd the different a sumptions made by each of the fish models when it comes to assessing the biological risks veTsus benefits of operations like the P A, which incorporate increased and un,.tested spill levels. To address this issue, we request the adoption of reliable fish monitoring and adaptive management solutions. Throughout the implementation of Flexible Spill, and as further adopted in this EIS, CEC urges the co-lead agencies to closely monitor the PA's untested operational approach, particularly, spill to 125% TDG. Efforts must include continual analysis of the proposed action and its impacts on ESA species, and the development of a robust monitoring approach and public platform to provide transparent feedback. We also encourage the co-leads to develop and improve upon an adaptive management framework to ensure their actions do not jeopardize the continued existence of any listed species.	Total Dissolved Gas (TDG) levels are regulated under the Federal Clean Water Act, and administered by the states. Both Oregon and Washington have reassessed the available data on effects of TDG levels up to 125% of saturation on fish and other aquatic organisms. Based on this reassessment, Oregon issued a five-year "standard modification" and Washington issued a permanent rule change, approved by the Environmental Protection Agency (EPA), to allow TDG saturation up to 125%. However, as noted by the commenter, there is considerable uncertainty in the effects; therefore, monitoring was required by the states and EPA to ensure any negative effects are detected and allow for adaptive management. Due to the disparity in the two model's forecasts for the Preferred Alternative and the uncertainty in the effects of TDG up to 125% on migrating salmon and steelhead, the Preferred Alternative includes a robust monitoring plan to help narrow the uncertainty between the biological models and help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored and effects from other sources such as harvest, ocean mortality, and straying will also be accounted for to the extent possible. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
3220	3	handerson@cec-co.com	N/A	Support for further study regarding socio-economic impacts of blackouts. We encourage the co-lead agencies to sharpen their analysis around this issue before issuance of the Record of Decision.	The commenter is correct that there could be socioeconomic effects if blackouts occur. The EIS methodology includes the full incremental replacement resource cost necessary to return the region to a level where the likelihood of blackouts is equal among all the alternatives, such that comparisons can be made among the alternatives on an equal basis. The EIS assumes for each Multiple Objective alternative (MO) that sufficient resources are acquired to reduce the risk of blackouts to the level of risk that existed prior to implementation of the MO. Once replacement resources have been acquired, the risk of a blackout for each MO is effectively the same as the No Action Alternative. The EIS evaluates the costs of replacement resource portfolios that would be required to avoid increasing the risk of an outage. See Draft EIS, Section 3.7. The approach in the analysis is to first evaluate the increased risk of power outages related to an alternative, and then identify what resources are needed to avoid that increased risk of an outage. Thus instead of identifying the potential socio-economic costs of power shortage, the analysis identifies the costs of replacement resource portfolios that would be required in order to avoid increasing the risk of an outage. If the EIS had then also added to each MO the additional cost of a blackout, then the MOs would have double-counted the impact of blackout risk (i.e. the MOs would have included the cost of avoiding blackouts and the costs of blackouts). The analysis identifies that the expected outcomes of MO3 and Multiple Objective alternative 4 (MO4) would be an increase in the cost of power and not in the risk of an outage. See Draft EIS, Sections 3.7.3.5 (MO3) and 3.7.3.6 (MO4). Because of the shape of the remaining hydropower generation in the Preferred Alternative, the loss of load probability was essentially the same as that of the No Action Alternative and identification of replacement resources was not necessary.
3222	1	cblack@rrelectric.com	Raft River Rural Electric Cooperative	RREC supports the Preferred Alternative (PA) contained in the DE IS as a balanced approach, but with some concerns.	Thank you for your comment.
3222	2	cblack@rrelectric.com	Raft River Rural Electric Cooperative	Realizing there will be costs associated with the PA, we ask that the proper care is taken to ensure the measures are not adversely impacting the ESA listed species. The flexible spill agreement imposes large amounts of untested spill to meet the requirements of the PA. It is my understanding that of the 2 bodies of science used in the DE IS analysis predict significantly different results for the survival of the ESA-listed species we are trying to protect. That is why RREC insists that as the co-leads continue to contemplate increasing spill up to 125% total dissolved gas (TOG) levels, these operations include strong monitoring measures and adaptive management	Under the ESA, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The co-lead agencies used current, high-quality information in the analysis of effects to ESA-listed salmonids in the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS Model predicts that average Smolt-to-Adult return rates (SARs) would increase for both Snake River spring Chinook and steelhead and would average above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing SARs from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to narrow the uncertainty between the two models and test how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
3222	3	cblack@rrelectric.com	Raft River Rural Electric Cooperative	In addition to unproven and unprecedented new levels of spill, we are concerned about other conditions that impact ESA-listed salmon species. For example, we are concerned with increased predation, not to mention the rising water temperatures in the ocean and streams that change based on conditions that we as power users cannot control. Again, economic impacts on our members are never easy to promote, but doing our part is nothing more than declaring good stewardship. However, if we are going to ask our members to sacrifice from the common good, we need assurance that the costs associated are actually working based on science, not emotion.	The co-lead agencies recognize that there are many effects to salmon and steelhead populations outside the operation of the dams; including those the commenter mentions. Research continues to evaluate the magnitude of these effects. For more information see the NMFS website at: https://www.nwfsc.noaa.gov/research/index.cfm. The EIS analyses relied on high-quality information and modeling, and co-lead and cooperating agencies' expertise, in the evaluation of effects of alternatives to resources. Based on the anadromous fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative (PA) would provide substantial benefits to ESA-listed species. The PA includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or TDG-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Specifically for the comment on predation, on-going actions described in the No Action Alternative to reduce predation on migrating fish are included in the PA. In addition, water management actions (Predator Disruption Operations measure) in the John Day reservoir are expected to further reduce avian predation on migrating juvenile fish. The No Action Alternative includes ongoing mitigation measures to haze and monitor pinniped predators. These actions would continue into the future under the PA, and the co-lead agencies would continue to assist National Marine Fisheries Service (NMFS), states and Tribes in their pinniped removal efforts near Bonneville Dam. For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7% relative to the No Action Alternative, consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to absorb through the costs it has significant control.
3222	4	cblack@rrelectric.com	Raft River Rural Electric Cooperative	I would now like to provide comments on Multiple Objective Alternative 3 (M03). This has been a controversial topic for years. The operation of the Lower Snake River Dams (LSRD) is essential to the goal of providing a reliable and economical power supply to the region. Although the removal of these dams may provide relief to some ESA-listed species, with the water temperature and predation issues, it is clearly not a sure fix all. The negative impact on the bulk power system makes M03 a non-option for our cooperative.	Multiple Objective alternative 3 was not identified in the Draft EIS as the Preferred Alternative. The information provided in the comment regarding the power-related impacts of breaching the four lower Snake River dams is consistent with the findings of the EIS. See Draft EIS, Section 3.7.3.5, Table 3-166; and Appendix H, Table 2-1. The EIS also discusses the fact that Bonneville customers, such as the cooperative mentioned in the comment, may be more directly affected by rate pressures than other regional utilities that do not purchase power directly from Bonneville. See Draft EIS, Section 3.7.3.5, Residential Effects, page 3-929.
3222	5	cblack@rrelectric.com	Raft River Rural Electric Cooperative	Realistically, with growing pressure on power providers to adopt stringent carbon free plans, removing the hydro resource shows complete disregard for improved and reduced carbon footprints. If these carbon free flexible and extremely reliable resources are removed (2000 MW), there will be much less chance of backing up renewables like wind and solar, without an increased loss of load probability or more plainly said, blackouts.	The EIS finds, consistent with this comment, that Multiple Objective 3 (MO3), which includes breaching of the four lower Snake River dams, would result in increased emissions from power generation. The comment that MO3 would increase the frequency of power shortages, unless and until replacement resources are acquired, and remove the renewables integration benefits of the four lower Snake River dams is also consistent with the findings of the EIS. See draft EIS, Section 3.7.3.5, Table 3-166 and Appendix H, Table 2-1.
3222	6	cblack@rrelectric.com	Raft River Rural Electric Cooperative	It is like paper products on the shelves of retail stores during the recent Covid-19 pandemic. Think for a moment if the region was suffering from those similar shortages of viable electricity. There are many essential services that continue to operate via technology using phones and the internet, all of which rely on power to operate. It may seem like an extreme example, but the reality is, removing flexible and extremely reliable hydropower base load contained in the LSRD, and the region is facing limited supply of resource, that may very well result in power shortages, causing blackouts. Granted, we can build alternate resources at a hefty cost, but not to be completely carbon free. There is simply no technology economically feasible that has a zero-carbon footprint as compared to Hydro Power.	The commenter's suggestion that hydropower is a reliable source of power is consistent with the findings of the EIS. The findings of the power replacement resources indicated that more capacity for zero-carbon resources (e.g., solar) were needed to address lower capacity factors, consistent with the commenter's concern. The higher costs for new renewable power, as described by the commenter, is also consistent with the descriptions and analysis of the EIS as described in Section 3.7.3.5, Potential Replacement Resources and Associated Costs, and in Table 3-166, Average Bonneville Wholesale Power Rate ($/MWh) under Multiple Objective 3, for the Base Case without Additional Coal Plant Retirements as well as the Rate Pressures Associated with Additional Sensitivity Analysis.
3222	7	cblack@rrelectric.com	Raft River Rural Electric Cooperative	Multiple Objective Alternative 4 (M04) is another option that could be as damaging to the bulk electric system as M03, as this would implement the highest level of spill across the entire CRS. The level of power generation decreased under average water conditions would be 1,300 aMW and 870 aMW under low water conditions. This seems to be obviously another alternative that simply cannot be tolerated if our goal is to meet the needs of providing a reliable and economical power supply. It also imposes large and untested levels of spill that could pose a diminishing effect on the ESA-listed species, depending on which model is used. To me, there is too much room for error. To impose these types of actions at the cost associated, could be considered wreck less	The information provided in the comment regarding the power-related impacts of Multiple Objective alternative 4 (MO4) are consistent with the findings of the EIS. See Draft EIS, Section 3.7.3.6, Table 3-182. Consistent with the comment, the Executive Summary and Chapter 7 explain why MO4 does not meet the objective developed for the EIS to maintain an adequate, efficient, economical and reliable, affordable power system. The Preferred Alternative identified in the Draft EIS meets the hydropower generation objective.
3224	1	nickwbacon@gmail.com	N/A	The notion that recreational opportunity would improve for the Valley if the slack water is gone is without merit. Firstly we already see existing benefit from the existing whitewater associated businesses as they use our community for supplies, lodging etc, so that would be a net zero "gain". Secondly Hells Gate State Park, Swallows Park, and Chief Timothy park would likely lose 100% of their waterfronts, which would in turn drastically reduce or eliminate their operations. Thirdly with no dams the Corps of Engineers would no longer need to maintain the levies and therefore the levee trails. Over 22 miles of local trail system would fall into disrepair as would the associated parks and the LC Valley would become disconnected from the Lewis & Clark National Historic Trail. Fourthly, the community would lose several public access beaches used by many (including low income families) to recreate and stay cool during the high temperature summers.	Section 3.11 describes adverse effects to existing recreation facilities and access points, which includes beaches, waterfront areas and trails in the Lewis and Clark Valley in Region C, that would occur under MO3, particularly in the short term. The adverse effects for any particular area are hard to predict with precision including at Hells Gate State Park, Swallows Park, and Chief Timothy Park but are expected to be adverse in general. In addition, Section 3.11 describes the need to develop recreation facilities, infrastructure, and/or recreational access under MO3 in the lower Snake region to facilitate new and emerging river recreation. As the region transitions to more river-based recreation, the EIS also describes some beneficial effects that are likely to occur.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
3250	1	Brian Hess	Inland Power and Light	After reading the report, I found the agencies preferred alternative, also known as MO1, to be mostly positive. I feel it is important to work toward a solution that addresses as many of the concerns as possible as they pertain to the lower Snake River dams. I was encouraged to see that MO1 calls to keep the dams on the lower Snake River in place. Since the passage of the Clean Energy Transformation Act and the Energy Independence Act, Washington utilities are working extremely hard to ensure the mandated clean energy requirements are met. While it is a steep order, the industry is committed to meeting those goals. We cannot, however meet these regulations without hydropower. It is important to note that increasing the level of spill would result in loss of power generation, thus creating higher costs for ratepayers. The DEIS states that MO1 has more than twice the risk of power shortages including blackouts and emergency conditions than the Northwest Power and Conservation Councils target for regional reliability. This is simply not acceptable. The state of Washington is already looking at a 7,000 MW delta once both coal and natural gas are removed from the states energy portfolio. It is imperative that we not lose clean energy production. According to the National Oceanic and Atmospheric Administration (NOAA), hydropower is necessary for meeting the state mandates for clean, carbon-free energy. The lower Snake River dams generate over 1,000 average megawatts of affordable, carbon-free electricity. They also help us safely add intermittent renewables, like wind and solar power, to the grid. The hydroelectric turbines at the dams can very quickly fill in the gaps for wind and sunshine, keeping the grid balanced.	The EIS does not identify MO1 as the Preferred Alternative as the comment states. The co-lead agencies developed a Preferred Alternative that includes a combination of measures from all of the Multiple Objective alternatives with consideration of environmental, economic, and social effects. Under the Preferred Alternative, regional power reliability is the same as the No Action Alternative; whereas MO1 analysis showed nearly twice the risk to regional reliability relative as the No Action Alternative. The comment that the four lower Snake River dams provide carbon-free energy and play an important role in the regional power system, particularly in regards to the integration of renewable power sources, is consistent with the findings of the Draft EIS in Section 3.7.3.5, Replacement Resources, and Section 3.8.3.5, Greenhouse Gas Effects of Multiple Objective alternative 3.
3250	2	Brian Hess	Inland Power and Light	After research, NOAA concluded that dams and salmon can coexist. It is also important to recognize the major fish passage improvements made to the lower Snake River dams. Over $2 billion has been invested in improved fish passage technologies for the lower Snake and lower Columbia river dams since 2001. These improvements have made a significant difference in juvenile salmon survival. Additionally, from 2001-2015 the lower Snake River experienced by far its highest adult salmon returns since the first lower Snake River dam was completed in 1961. I urge the agencies and regulatory bodies take MO1 seriously as it would benefit the vast majority of stakeholders and result in the most collaborative good for the region.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. Multiple Objective alternative 1 (MO1) met the objectives for implementing adaptable water management strategies, water supply, ESA-listed juvenile and adult anadromous fish and resident fish. However, the expected degree of improvements to ESA-listed salmonids was less than was desired by the co-lead agencies. Under MO1, there would likely be moderate adverse effects to water quality in the lower Snake River, and there would also likely be moderate adverse effects to resident fish in the upper Columbia River Basin due to changes in reservoir operations and elevations that would require mitigation. There would likely be no major or moderate economic effects under MO1, but there are major social effects, including adverse impacts to cultural resources at Hungry Horse, Lake Roosevelt and Dworshak reservoirs. MO1 was not identified as the Preferred Alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
3315	1	N/A	N/A	See Attachment...	Unfortunately, an attachment was not received from the commenter. The commenter did not provide any contact information the co-lead agencies could use to request these comments, so a response was not provided.
3379	1	jerrydairy@cablespeed.com	N/A	Rather than remove the dams, Just OPEN them to lowest capacity. Then wait a year or two. If you find you have not destroyed the system, then you can proceed with removal.	As stated in Chapter 2, the co-lead agencies developed the reasonable range of alternatives to meet the objectives and the Purpose and Need Statement. The purpose and need describes the congressionally-authorized purposes of the system, which include hydropower generation, inland navigation, and irrigation, among others. Sections 7.3 and 7.4 of the EIS provide a descriptive comparison of the alternatives evaluated. This information is also provided in Table 7-1, Evaluation of Alternatives. Opening the dams is an unreasonable alternative given the potential risks to public health and safety from impacts such as power and transmission reliability and flood risk management.
3430	1	bbrokens@msn.com	N/A	Please see attached letter, which reflects my views on removing the dams in the columbia river drainage.	Unfortunately, an attachment was not received from the commenter. The co-lead agencies requested the commenter resubmit via e-mail on June 25, 2020; however, the co-lead agencies did not receive a response to this request.
3455	1	mhabailey@comcast.net	N/A	SAVE THE PLANET SAVE THE DAMS I live in Tetonia, Idaho and my electric provider is Fall River Electric. It has come to my attention that you are looking at closing some of the dams in the area that will affect me and my home. Please consider the families and farms that this will impact and leave them alone. See attached letter below.	Unfortunately, an attachment was not received from the commenter. The co-lead agencies requested the commenter resubmit via e-mail on June 25, 2020; however, the co-lead agencies did not receive a response to this request. Multiple Objective alternative 3, which included the measure to breach the four lower Snake River dams, was not identified in the Draft EIS as the Preferred Alternative.
3502	1	glenb@inlandpower.com	N/A	While it is not completely amenable to the utility industry, it certainly addresses our primary concern, which is keeping the dams on the lower Snake River in place. This component of MO1 is most definitely a move in the right direction. The increasing regulations facing Washingtons utility industry continues to put pressure on the states electric grid. The push for carbon-free energy is something that simply cannot be done with the use of hydropower. The notion that the lower Snake River dams dont contribute a significant amount of power is nothing more than a myth and misguided argument. These vital dams produce enough carbon-free energy to power 1.87 million homes.	Consistent with the comment, the EIS finds that replacing hydropower generation from the four lower Snake River dams would increase carbon dioxide emissions. EIS, Section 3.8.3.5, 3-1009-1010 in the draft EIS. While the EIS finds that it would take even more renewable resources to replace the four lower Snake River dams generation while the region is retiring coal plants, the question of whether the dams are essential in reaching Northwest clean energy goals was not addressed in the EIS. See draft EIS, Section 3.7.3.5, Potential Replacement Resources And Associated Costs at pages 3-904-905 and Table 3-160 in the Draft EIS. Consistent with the comment, these dams are an important component of the Federal Columbia River Power System. They provide approximately 1,000 aMW of carbon-free energy on average and 2,000 MW of sustained peaking capacity at certain times of the year. See draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. The dams also provide important ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907 and Table 3-160.
3502	2	glenb@inlandpower.com	N/A	The MO1 does a great job of noting the importance of dams and salmon coexisting. The National Oceanic and Atmospheric Administration (NOAA) agrees that these power-generating resources and this vital specie can exist together at the benefit to all in the Pacific Northwest. Salmon pass through many different ecosystems in their life cycles. The ocean is where Chinook salmon spend 75% of their lives. In 2019, the Intergovernmental Panel on Climate Change warned that climate-driven changes have become a major threat to marine life in ocean ecosystems. They said that these changes are poisoning our oceans with carbon, heat, and acidity and depleting the waters of oxygen. Its not surprising that marine biologists have recently noted near-synchronous declines in worldwide salmon populations. Most of these salmon populations come from rivers without dams.	The co-lead agencies concur. The decline of salmon populations is complex and recovery of those species will take collaboration between various agencies including NOAA and the tribes. The co-lead agencies acknowledge that the ocean environment is a contributor to the decline in salmon populations that is beyond the scope of the CRSO EIS. While none of the alternatives would affect ocean conditions, we recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of this environment in the return of adult salmon and steelhead (Peterson et al. 2019). As such two of the models used in these analyses, NMFS Life Cycle and CSS models, use metrics of ocean productivity to predict adult returns. The carbon-free attributes of the Federal hydropower system are described in the Air Quality section of the Draft EIS (section 3.8).
3502	3	glenb@inlandpower.com	N/A	Meanwhile, the lower Snake River dams can displace as much carbon as would be produced by two Boardman coal plants running 24 hours a day, 365 days a year.	Section 3.8.3.5 of the EIS provides information on the greenhouse gas (GHG) emissions effects of Multiple Objective Alternative 3 (MO3), which includes breaching the four lower Snake River dams. The analysis evaluates GHG emissions effects assuming a range of replacement resource scenarios. At the high end, the analysis finds an increase in GHG emissions of 3.3 MMT CO2 under MO3, if the replacement power resources are natural gas (the least cost replacement).
3508	2	badgercaddis@mac.com	N/A	Im interested in preserving our access to a carbon free, reliable, and historically low-cost federal hydropower generation, and therefore support the Preferred Alternative (PA) contained in the DEIS as a balanced approach that benefits the ESA-listed species, meets the multiple purposes of the federal projects, and minimizes adverse economic, environmental, and social impacts, although the PA comes at a cost to me as an electric cooperative member.	Thank you for your comment. In developing the Preferred Alternative, one of the objectives was ensuring reliable and affordable power. The Preferred Alternative allows the co-lead agencies to continue to operate the facilities for their congressionally authorized multiple purposes, including fish and wildlife, water supply, navigation, flood risk management, and recreation.
3508	3	badgercaddis@mac.com	N/A	These dams are a key source of low-cost, carbon free power.	This comment is consistent with the discussions and findings of the EIS in Sections 3.7.3.5 and 3.8.3.5 regarding increases in power rates and greenhouse gas emissions under Multiple Objective Alternative 3 (which includes breaching the four lower Snake River dams).
3508	4	badgercaddis@mac.com	N/A	Overall juvenile survival of salmon and steelhead through the Columbia River system is 40% to 50%, depending on the species, which is comparable to free-flowing rivers such as the Frasier River in Canada.	The co-lead agencies concur with the generalized survival rates through the CRS. The co-lead agencies advise caution when directly comparing survival rates between different populations of fish or from different geographical locations. See ISAB 2020-1 for discussion of comparing populations, even populations within the Columbia Basin.
3508	5	badgercaddis@mac.com	N/A	The Lower Snake River dams are some of the lowest cost generation marketed by BPA and are increasing in value as the region sets greenhouse gas (GHG) emission goals.	This comment is consistent with the discussions and findings of the EIS in Sections 3.7.3.5 and 3.8.3.5 regarding increases in power rates and greenhouse gas emissions under Multiple Objective alternative 3 (which includes breaching the four lower Snake River dams).
3508	6	badgercaddis@mac.com	N/A	They provide substantial energy, operating reserves and ramping capability to help prevent blackouts and integrate other variable renewable generation like wind and solar. They have also been built to facilitate fish passage with a spring juvenile survival rate of 96%, which meets performance standards.	The statement that the four lower Snake River dams provide reserves and ramping capability that benefit regional power reliability is consistent with the discussions and findings of the EIS. The survival rate referenced in the comment is put in context in the Draft EIS on page 3-303: To aid the downstream passage of juvenile salmon and steelhead, the co-lead agencies have worked to improve passage and survival past the dams and through the reservoirs of the CRS. Figure 3-114 in the Draft EIS, shows recent estimates of survival at the eight lower CRS projects with fish passage. The dam survival estimates do not include system-wide or latent effects (see Section 3.5.3.1). These estimates were developed to show progress towards meeting the individual dam survival goals developed during the 2008 Biological Opinion of 96 percent survival past each dam for yearling Chinook and steelhead, and 93 percent for Snake River sub-yearling fall Chinook. Section 3.5 also discusses system survival rates, as well as latent mortality. The analysis of alternatives presents estimates of survival rates from Lower Granite to Bonneville dam (eight dams) for Snake River spring/summer Chinook and Snake River steelhead from two different models, with the estimates ranging from 40-60%. The mechanism and magnitude of latent mortality are not well understood, as presented in the discussion of Independent Scientific Review in Section 3.5.3.1, Methodology.
3508	7	badgercaddis@mac.com	N/A	This reports conclusions on fish and wildlife are consistent with past findings which show the lower Snake River dams do not jeopardize the existence of threatened and endangered salmon species that navigate past them.	The co-lead agencies refer the reader to analysis by NMFS and the US Fish and Wildlife Service for official determinations on Jeopardy or No-Jeopardy associated with the Preferred Alternative/Proposed Action. Final Biological Opinions from the two services will be released concurrently with the Final CRSO EIS.
3508	8	badgercaddis@mac.com	N/A	I am concerned about global warming. With regional efforts aimed at reducing carbon and moving to a carbon free generation portfolio, having access to the carbon free, reliable and flexible generation will be essential to ensure the regions power system reliability and will be essential in meeting the regions GHG goals.	The comment cites the importance of hydropower for achieving regional clean energy goals and integrating renewables onto the grid. Although it is beyond the scope of the EIS to analyze the role of hydropower in achieving specific clean energy goals, the EIS does find that replacing lost hydropower generation in MO3 and MO4, even with zero-carbon resources, would increase greenhouse gas emissions from power generation by increasing operation of existing fossil-fuel based generation. EIS, Section 3.8.3.5, 3-1009-1010 in the Draft EIS and 3.8.3.6, 3-1021-1022 in the Draft EIS. The statements regarding the variability of other renewables and the importance of the four lower Snake River dams for integrating new renewables are consistent with the findings and discussions in the EIS. EIS, Appendix J, Section 4.3, Integration of Other Renewable Resources and Hydrosystem Flexibility Analysis.
3508	9	badgercaddis@mac.com	N/A	I encourage cooperation with environmental and Tribal groups to work on plans which do bolster a sustainable salmon and steelhead population. Specifically, I support efforts to manage avian and other predation of salmon populations.	As described in the Preferred Alternative, the co-lead agencies propose several measures to reduce avian and marine mammal predation to mitigate adverse effects to listed species from CRS operations. Ongoing actions described in the No Action Alternative to reduce predation on migrating fish are included in the Preferred Alternative. The No Action Alternative includes ongoing mitigation measures to haze and monitor pinniped predators. These actions would continue into the future under the Preferred Alternative, and the co-lead agencies would continue to assist National Marine Fisheries Service (NMFS), states and Tribes in their pinniped removal efforts near Bonneville Dam. The Preferred Alternative also includes the Predator Disruption Operation to discourage nesting within the John Day reservoir. The projects monitoring and adaptive management plan (Appendix R, part 1) includes monitoring to determine the measure effectiveness on reducing the avian predators nesting habitat. As analyzed in Section 7.7.7, the Predator Disruption Operations measure could delay in nesting waterbirds, forego nesting, or relocate to other areas. As discussed in Section 3.6.3.2, Caspian terns are highly mobile during the breeding season and move between breeding colonies in a given year and between years, demonstrating a willingness to nest away from the Columbia River while still foraging on juvenile salmonids (Corps 2014, 2018, 2019).
3508	10	badgercaddis@mac.com	N/A	I am also concerned about the long-term cost of power. Many of my friends and neighbors are seniors and have fixed or low incomes. In our area we are also dependent on electric service for our water from wells, our electric heat, electric water heaters, wastewater and sewage treatment. Many in our area are particularly vulnerable to increased risks of blackouts and escalating power costs, which makes the PA worthy of my support in terms of its lower risks in these areas compared to other DEIS alternatives.	The EIS recognizes concerns around the affordability of electricity, and the Environmental Justice analysis (Section 3.18.3 and Section 7.7.20 of the EIS) provides further detail on this as well as the potential disproportionate effects to tribal, low-income and minority populations. The statement that the Preferred Alternative preserves regional power reliability and does not increase the likelihood of blackouts is also consistent with the findings of the EIS. The EIS also discusses potential health and safety concerns associated with the increased risk of blackouts.
3510	1	N/A	N/A	Please try to find a good compromise. Maybe improved fish ladders would help.	Thank you for your comment and your idea. A wide array of measures were considered during the creation of alternatives for these analyses. While fish ladders at CRS projects are considered to be effective at safely passing adult salmon, the preferred alternative was developed with balance in mind to support positive improvements in the many complex objectives associated with operative the multi-purpose projects.
3510	2	N/A	N/A	How about asking the various tribes to limit fishing?	The focus of the EIS is the operation, maintenance, and configuration of the Columbia River System. Fishing and harvest are subject to separate actions by federal, state, and tribal agencies outside the scope of this EIS. Additionally, the co-lead agencies have no authority to regulate fishing.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
3556	1	palousemayor@gmail.com	N/A	Breaching the dams, as westside environmental groups advocate, would take away our least expensive and least carbon-intensive method of transportation: barging. In turn, the loss of barging could increase transportation costs 10-33 percent, according to your draft report. In addition, we would lose access to nearly 48,000 acres of irrigation, causing a $500 million social welfare loss, according to the report. Its sobering to think of the impacts to family farms. A study by the Pacific Northwest Waterways Association estimates more than 1,100 farms risk bankruptcy if the federal government does not increase farm subsidies. With wheat prices already down near the break-even point, annual direct payments to farmers would need a boost of $38.8 million to maintain current income levels.	The concerns raised in the comment are consistent with the analysis in the EIS. The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. Evaluating the impact of removing the lower Snake River locks and barge navigation above Pasco, Washington, is completed using a transportation optimization model that does not allow shipments on river terminals along the lower Snake River. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations, shuttle rail facilities or river ports on the Columbia River, would be the most negatively impacted. NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The mitigation requested is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide direct payments to farmers related to increased operation costs.
3562	1	aloise.ca@gmail.com	N/A	So, we are, now, in 2020, Salmon population has further declined. For example, Snake River sockeye salmon were listed as endangered in November 1991, and their listing was reaffirmed in June 2005. This list, from 2005, includes Five anadromous salmon populations and three anadromous steelhead trout populations present in the LSRP. And nothing, in your actual or past EIS, indicate the repercussions on the greater environment of the ocean, including Resident Southern Killer Whales, who are directly impacted by, has they were placed on the endangered species list in 2005.	SRKW analysis is described in the EIS including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) which has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
3571	1	N/A	N/A	If you want to address the global salmon and the lack there-of, go address the lobbying and dirty money that is spent by the commercial seiners. Then cut back the salmon limits, and all fishing limits and you will see the return of the salmon.	Alternatives to include changes to harvest are not within the scope of this EIS. The assumptions regarding harvest are taken from the 2018 EIS from NOAA and reflect current harvest management guidelines. For harvest, fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and Tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (i.e., NMFS), and Tribal fishery managers based on a variety of environmental, biological, economic, and social factors. The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so.
3571	2	N/A	N/A	The commercial seiners are where you need to start and then if needed cut back on recreational limits	See response to Comment 3571-1.
3574	1	N/A	N/A	The DEIS dismisses the overwhelming scientific research that shows restoring the lower Snake River to its free-flowing condition will provide salmon and steelhead with their best and likely only chance to recover, and it ignores the benefits of increasing salmon runs for critically endangered Southern Resident orcas. These orcas primarily eat Chinook salmon and forage for these fish from central California into the Salish Sea. The Columbia and Snake rivers have supported salmon runs that the orcas have relied on for centuries. Historically, nearly half of all the Chinook salmon returning to the Columbia Basin were bound for the Snake River. Scientists from the Fish Passage Center have stated that breaching the four lower Snake River dams would result in roughly one million adult Chinook salmon returning to the mouth of the Columbia River, providing a critical food source for endangered southern resident orcas.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (tules and brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. 					salmon and steelhead hatchery production. The FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
3574	2	N/A	N/A	The DEIS presents a false choice between maintaining affordable utility bills and restoring healthy salmon and steelhead. It overstates the cost of replacing power from the lower Snake River dams with clean energy, and suggests replacing their power with fossil fuels, which is unnecessary. A report from the Northwest Energy Coalition shows that through strategic investments, the energy produced by these dams can be replaced at a marginal cost to ratepayers while also improving the reliability of the electrical grid.	The EIS evaluated effects associated with the management of the CRS, and did not quantitatively compare the benefits of the power system against the costs to salmon. The EIS describes the replacement resources that would be needed to maintain regional reliability at the No Action Alternative levels based on two potential portfolios: one based on renewable resources and another based on natural gas resources, which are generally the least cost means to maintain reliability (see Draft EIS at Section 3.7.3.5, Potential Replacement Resources and Associated Costs). The EIS uses the best available resource cost information from the Northwest Power and Conservation Council to estimate the potential range in costs of these replacement resources. In addition, the EIS does not suggest fossil fuels should be used to replace the power; the purpose of providing the range of replacement resource options is to estimate a reasonable range in potential costs. The basis for developing both of these portfolios is in Section 3.7.3.1, Methodology, of the Draft EIS. As described in Appendix H, Power and Transmission, and Section 3.7.3.5, the EIS considered the Northwest Energy Coalition study cited in the comment but it is not directly comparable with the EIS for several reasons, including that the EIS has a broader scope and relies on more recent regional load and resource availability and costs data.
3574	3	N/A	N/A	The DEIS focuses on the financial costs of salmon recovery and ignores the enormous sacrifices that have already been made by Native American tribes and other Northwest residents in terms of lost fishing opportunity, reduced jobs and incomes, impacts on cultural values, and other socio-economic effects.	The EIS recognizes the economic and cultural importance of salmon to Tribes in a number of sections throughout the document. Section 3.15, Fisheries and Passive Use Section and, in particular, Section 3.17, Indian Trust Assets, Tribal Perspectives, and Tribal Interests, include discussions of reductions in anadromous species catch and associated adverse social effects that have occurred in Tribal communities. The cultural significance and impacts of salmon and steelhead fisheries are described in Section 3.15.2.1, Fisheries and Passive Use, which includes subsections that describe ceremonial and subsistence fisheries as well as the social importance of commercial, ceremonial and subsistence fisheries.
3574	4	N/A	N/A	Further, the DEIS ignores the economic and community benefits of salmon recovery and the investments and jobs that river restoration activities will generate.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4 of the Preferred Alternative, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The EIS also provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which are described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the Multiple Objective alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. Additionally, Section 3.19.3 and Appendix Q, Annex C, describe the construction expenditures and the resulting jobs and income supported by the construction activity associated with the dam breach under MO3. The EIS considers the jobs supported by the implementation and CRSO EIS system costs, including mitigation costs described in Chapter 5 and in Annex B of Appendix Q.
3574	5	N/A	N/A	As written, the DEIS does not provide a complete or accurate assessment of the feasible alternatives for the lower Snake River. An effective solution for Northwest salmon and people must move beyond historic conflicts and proactively address four urgent, connected issues. I support the development of long-term plan to: Restore abundant, fishable salmon and steelhead populations in the Columbia Basin; Protect and invest in the economic vitality of local farming and fishing communities; Continue the regions legacy of providing reliable, affordable, clean energy; and Honor our nations treaty commitments to Native American tribes	The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, Tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions and solutions for mitigating the effects of the CRS and achieving broader recovery objectives. The Preferred Alternative for long-term system operations, maintenance and configuration of the CRS presented in the Draft EIS is based on todays conditions and environment. Its also important to note that technology is quickly changing, as is the regions dynamic environment and energy market, and the region needs to consider new information and adaptively manage resources. The co-lead agencies recognize that no matter which alternative in the CRSO Draft EIS is identified as the Preferred Alternative, the identification would likely draw criticism from some stakeholders or sovereigns. The region includes stakeholders, sovereigns, and other interested parties with diverse and varied opinions on these very important topics, and many are strong in the belief that their perspective is the best path forward. It is important to keep in mind that factors, both human-caused and natural, that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. The co-lead agencies look forward to participating in that discussion.
3580	1	timo@inlandpower.com	N/A	An area of MO1 that concerns me is the mandatory spill. While spill is nothing new, the preferred alternative would require a spill rate much higher than we are currently experiencing, which would have a 2.7% wholesale rate increase impact. This also equates to 160 aMW loss during a normal water year, and 300 aMW loss during a low water year. With the lower Snake River dams producing enough energy to deliver power to 1.87 million homes, this loss in energy production would put further stress on the grid as demand increases and supply decreases.	Multiple Objective alternative 1 was not proposed as the Preferred Alternative. The hydropower statistics described in this comment are consistent with the Preferred Alternative results described in Chapter 7 of the EIS. However, while the total hydropower output of the Federal Columbia River Power System declines, the reliability of the system under the Preferred Alternative improves relative to the No Action Alternative due to the timing and magnitude of hydropower generation. The Preferred Alternative would be implemented using a robust monitoring plan to help evaluate the effectiveness of the spill program, as would the effects to generating resources around the basin. The statement that removing the four lower Snake River dams would increase stress on the grid is consistent with the findings of the EIS. The EIS recognizes the concern voiced in the comment regarding increasing power rates. Under the Preferred Alternative, which includes juvenile fish passage spill operations contemplated under the 2019-2021 Spill Operation Agreement, the Bonneville's wholesale power rate pressure is 2.7 percent relative to the No Action Alternative. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement, and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to absorb through the costs over which it has significant control. See Draft EIS Section 3.7.3.1 at page 3-187.
3583	1	N/A	N/A	I would like to see a more aggressive pursuit of adaptive upstream travel for the salmon applied to the dams, as well as oceanic policy review. I realize that recreational, commercial and tribal "take" is part of coastal and riverway economics and culture, but I believe that we need to view the whole West Coast Fishery as an ecosystem.We can't just keep looking at the parts of the whole.	The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so. An evaluation of the West Coast fisheries is outside the scope of this EIS. Fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and Tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (e.g., NMFS), and Tribal fishery managers based on a variety of environmental, biological, economic, and social factors.
3592	1	lrentfrow@msn.com	N/A	The comment period was insufficient. 45-days is woefully inadequate to review a plan of this complexity and many people had trouble getting through on the phone hearings.	We are sorry you had technical difficulties. We hope you were able to provided comments into the online form or through mail. The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. The CRSO EIS website reminded the public on April 9, that they should plan to submit comments by the close of the comment period.

3603	1	N/A	N/A	Get rid of the predators and fish nets.	Predation management measures are included in the Preferred Alternative, as well as the continuation of predation management measures from the No Action Alternative. These measures are described in Chapter 7. Methods of fish harvest and their regulation are outside the scope of this EIS, which analyzes the effects of the operation, maintenance, and configuration of the CRS. The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so. Additionally, the use and disposal of fishing gear is not managed by the co-lead agencies.
3605	1	curdog1@charter.net	N/A	Section 3.19.2, page 3-1477 It is a global comment on the discussion of the MOs Annual Equivalent Costs. The EIS suggests the MOs either have small increases or as MO-3 states Under MO3, total costs are anticipated to decrease between 159 and 54 million annually or between 15.1 to 5.1 percent decline compared to the NAA. This is somewhat misleading as the EIS clearly shows the cost to replace the loss of power generation is very expensive. See attached spread sheet Power Generation Mitigation Cost. The cost of power generation portfolios that would be required to be designed and build with capital costs, then the operations and maintenance costs to maintain an equivalent Loss of Load Probability is not included in section 3.19.2. In addition, the cost of the lost revenue from the MO scenarios is not captured or the cost of the GHG that will be generated from the loss of the hydro power. As discussed in section 3.7.31, page 3-821, Bonneville and other regional entities would have to decide who is responsible for acquiring the replacement resources. To make a fair comparison of the costs associated with the EIS alternatives, they need to be factored in. It does not matter who is responsible for the replacement costs, as they would occur as described in the EIS. These costs need to be factored in to show there is a cost associated with loss of power generation. Page 3-873, The social welfare analysis employs both market price and production cost methods based on the base case for this analysis, assuming no additional coal plant retirements. The market price method estimates the societal loss or gain from changes in power generation, valued at monthly market price while production cost method estimates fixed and variable costs both power and transmission, associated with providing power. The two approaches are not additive There are numerous approaches on how to capture a summary of the costs, I propose to use the production cost estimate method as it captures the overall cost. Im not sure if the cost of carbon compliance is included or not, but for the overall summary comparison it is not overly relevant. To keep it simple I propose to use an average of the production cost method estimate and add it to the Annual Equivalent Costs (Low F&W Cost) page 3-1481. See attached spread sheet. Table 3-309, page 3-1481 should reflect these costs and the percent increase adjusted for clarity.	This comment is combining two distinct analyses from the EIS. The first is the cost analysis which focused on estimating the implementation and system operations and maintenance costs for each CRSO EIS Multiple Objective alternative (MO), including dam breaching under MO3. The second set of costs are the estimated costs to construct replacement power resources as described in Section 3.7. The EIS does not sum all costs associated with MO3 in Section 3.19. However, a summary of the benefits and costs for a number of the alternatives has been provided in Section 7.7.21 in the Draft EIS. The EIS evaluated the full value of any loss of revenue from hydropower in Section 3.7.3 by performing a complete reliability analysis, operational study for each MO, and a complete rate analysis at the wholesale, and then retail level. The increase in greenhouse gas emissions from the loss of hydropower is discussed in Section 3.8.3, Air Quality and Greenhouse Gases. The increase in emissions was quantified based on power plant emissions and monetized using the social cost of carbon. In addition, while the costs of replacement resources were not included in the distinct cost analysis, Section 3.7.3.5 in the Draft EIS provides details on the methodology and results of the replacement resource costs. To evaluate socioeconomic effects of resource replacement, the EIS analyzes how these costs affect retail electricity rates as described in Appendix J. The recommendation to estimate social welfare effects using the production cost method is consistent with descriptions in the EIS. The costs of potential carbon compliance are not included in the production cost method estimates because those costs cannot currently be determined due to uncertainty with the legislative requirements for the cost of carbon. The values presented in the EIS for potential carbon compliance offer a range, if binding estimates for the cost of carbon were enforced. The production cost method does assess all variable costs including potential emissions penalties stemming from fossil fuel generation in California. However, the EIS does not sum these power replacement resource costs together with the costs of implementing the alternatives in Section 3.19, as suggested in the comment.
3610	1	N/A	N/A	See attached comment letter.	Unfortunately, an attachment was not received from the commenter. The commenter did not provide any contact information the co-lead agencies could use to request these comments, so a response was not provided.
3616	1	scott@ecotonephoto.com	N/A	I appreciate all the hard work they have done over the years and continue to do to help keep salmon and steelhead from going extinct. However, in looking at the current available data, it becomes apparent that removal of the lower four Snake River dams will increase flexibility in the system, not decrease it. First, it should be of noted that in the Pacific Northwest power grid there is a 17.1% power surplus that is predicted to exceed customer demands until 2028. The lower four Snake River dams only produce 3.9% of the energy in the Pacific Northwest all of which is essentially in the surplus category. This disputes the logic in itself. Even with the removal of the lower four Snake River dams, our region would remain in surplus levels until a predicted 2026. If the surplus is what is giving agencies relief, no immediate impacts would occur and there would be plenty of time to plan for future relief. On that note, BPA already has plans in their queue to replace and far exceed the energy produced by the lower four Snake River dams (only 940 aMW/year).	The statement that removing the lower Snake River dams would increase flexibility is inconsistent with the findings of the EIS. In Section 3.7.3.5 of the EIS, Potential Replacement Resources and Associated Costs, the four lower Snake River dams are among the most valuable projects in the Federal Columbia River Power System (FCRPS). They provide approximately 1,000 aMW of carbon-free energy on average and 2,000 MW of sustained peaking capacity at certain times of the year. See draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. The dams also provide important ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See draft EIS, Section 3.7.3.5, Lower Snake River Full Replacement at pages 3-905-907 and Table 3-160. In other words, it is not enough to consider the amount of generation from these dams in assessing their importance, but also to consider the timing of that generation. Regarding surplus, Bonneville sells power from the FCRPS as a unified system, not from specific projects. In this regard, the power generated from the four lower Snake River dams are not exclusively sold as surplus, but rather is used to meet Bonneville's collective power obligation, most of which is sold to meet the loads of publicly owned utilities, such as municipalities, rural utilities, and public utility districts. (See Section 3.7.2.5, Bonneville Power and Transmission Customers in the draft EIS). Given upcoming coal retirements, the EIS findings indicate that the region would likely require more power resources to maintain power system reliability as described in the Bonneville Transmission System Reliability and Operations subsection of Sections 3.7.3.3 through 3.7.3.6 and in Section 3.7.3.5, Potential Replacement Resources and Associated Costs. While the four lower Snake River dams account for a small portion of the total power of the region, they represent a larger portion of the Federal Columbia River Power System (FCRPS) from which Bonneville supplies firm load. The comment also suggests that the region could absorb this loss because on average the region has surplus energy. To determine resource replacement amounts, the EIS uses a more robust measure of power system reliability and resilience than the average MWs approach suggested by the commenter. Specifically, the EIS uses the loss-of-load probability (LOLP) metric utilized by the Northwest Power and Conservation Council. See EIS Section 3.7.2.2; Appendix H Power and Transmission, at Section 2.1; Appendix I Hydroregulation, Section 2.4.4 in the draft EIS. The LOLP metric evaluates the adequacy of power supply in the region to meet firm power needs under various conditions. It is measured in terms of a percentage, and represents the likelihood of a year having one or more blackouts. See Appendix H Power and Transmission at Section 2.1 in the draft EIS. The current LOLP under the No Action Alternative is 6.6 percent; this is equivalent to one year with blackouts every 15 years. The EIS uses this LOLP level as the benchmark from which to compare the other Multiple Objective (MO) Alternatives. As the commenter notes, under MO3, on average, the region has surplus generation leading to export sales during certain periods and water years. Nevertheless, to maintain regional reliability at the LOLP levels of the No Action Alternative, replacement resources would be needed. This is driven by the timing and magnitude of changes in hydropower generation analyzed in the EIS. As shown by the analysis of the LOLP, in some years and times of the year, particularly winter and later in the summer of drier years, without the four lower Snake River dams there would be insufficient power supply in the region leading to power emergencies and blackouts. Specifically, without replacing the power from the four lower Snake River dams, the LOLP of the region would more than double to 14 percent, which is equivalent to one year with one or more blackouts every seven years. See page 3-903 and Appendix H, Power and Transmission, at Table 2-1 in the draft EIS. Contrary to the comment, Bonneville does not have plans to replace 940aMW/year of FCRPS output.
3619	1	bluebug@hevanet.com	N/A	Any plan for salmon recovery on the Columbia and Snake Rivers must incorporate the following: - Removal of the 4 obsolete dams on the lower Snake River -Increase flow rates over Columbia River dams to lower water temperatures -Updated salmon conservation and restoration strategies in line with guidelines following federal court five time rejection of previous agency strategies -Halt of unnecessary scapegoating of native wildlife for declines in salmon numbers -Inclusion of stakeholders in crafting inclusive, creative, proper solutions, including Indigenous peoples, environmental groups and communities along the river systems -Halt of sport and commercial fishing for salmon and sturgeon on the Columbia and Snake River systems by all but Indigenous peoples until fish recovery equals sustainable numbers	The purpose of the CRSO EIS is not salmon recovery. Section 1.2 provides the Purpose and Need Statement for the CRSO EIS. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, Tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions and solutions for mitigating the effects of the CRS and achieving broader recovery objectives. The Preferred Alternative for long-term system operations, maintenance and configuration of the CRS presented in the Draft EIS is based on todays conditions and environment. Its also important to note that technology is quickly changing, as is the regions dynamic environment and energy market, and the region needs to consider new information and adaptively manage resources. The co-lead agencies recognize that no matter which alternative in the CRSO Draft EIS was identified as the Preferred Alternative, the decision would likely draw criticism from some stakeholders or sovereigns. The region includes stakeholders, sovereigns, and other interested parties with diverse and varied opinions on these very important topics, and many are strong in the belief that their perspective is the best path forward. It is important to keep in mind that factors, both human-caused and natural, that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. The co-lead agencies look forward to participating in that discussion. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so. An evaluation of the West Coast fisheries is outside the scope of this EIS. Fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and Tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (e.g., NMFS), and Tribal fishery managers based on a variety of environmental, biological, economic, and social factors.

3625	1	roboberdorfer@gmail.com	N/A	I also wanted to lodge my complaint about the 45-day public comment period, which with COVID-19 concerns reflects a rush to enact bad policy.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings s in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate as per NEPA regulations. The CRSO website reminded the public on April 9, that they should plan to submit comments by the close of the comment period.
3637	1	N/A	N/A	The DEIS projects a 10 to 33 percent increase in transportation costs. The cost to transport wheat, which made up 87 percent of the cargo shipped down the lower Snake River in 2018, could increase by $0.07-$0.24 per bushel. As a result, the federal government would have to increase farm subsidies by $38.8 million to maintain farmers' current income levels, according to the Pacific Northwest Waterways Association.	The concerns raised in the comment are consistent with the analysis in the EIS. The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. Evaluating the impact of removing the lower Snake River locks and barge navigation above Pasco, Washington, is completed using a transportation optimization model that does not allow shipments on river terminals along the lower Snake River. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most negatively impacted. NEPA requires that all relevant, reasonable mitigation measures that could diminish the adverse impacts of the project be identified in the document, even if they are outside the jurisdiction of the lead agency or the cooperating agencies. See 40 C.F.R. 1502.16(h) and 1505.2(c); 46 Fed. Reg. 18026. The inclusion of mitigation measures in this Chapter 5 of the EIS is not intended to indicate that the co-lead agencies, or the Federal government as a whole, has the authority to perform all of the measures listed. If the measures are outside the jurisdiction of the co-lead agencies, those measures will not be included in the Preferred Alternative or Records of Decision (ROD). Their inclusion in Chapter 5 of the EIS serves to alert other agencies, officials, and the public who can implement the measures to the potential benefits of the measure. The mitigation requested, while identified in the Draft EIS, is not within the co-lead agencies' current authorities. The co-lead agencies do not have the authority to provide direct payments to farmers related to increased operation costs.
3641	1	N/A	N/A	I would add an additional component to alternatives 1 & 2 - COMPLETE cessation of ALL fishing for any of the species of fish that this plan is attempting to improve.	The three co-lead agencies (Corps, Reclamation, and Bonneville) do not manage fish stocks, and do not have the authority to do so. An evaluation of the West Coast fisheries is outside the scope of this EIS. Fisheries in the Columbia River Basin and those that rely upon Columbia River fish stocks are managed by numerous entities, including Federal, state, and Tribal governments. These entities are guided by a complex array of policies, laws, compacts, and agreements. The management of Pacific salmon fisheries in particular is complex, and involves numerous entities representing a variety of social, political, and conservation interests. Changes in allowable fishery harvest in the Columbia River Basin are a result of decisions made by state, Federal (e.g., NMFS), and Tribal fishery managers based on a variety of environmental, biological, economic, and social factors.
3644	1	N/A	N/A	I am also a bit shocked that you are shortening the public comment period to only 45 days. The way to move forward is to involve all stakeholders including indigenous tribes, communities and policy makers to come up with a true solution.	The comment period was the 45 days as required by NEPA and had not been shortened. The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings s in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate as per NEPA regulations. The CRSO website reminded the public on April 9, that they should plan to submit comments by the close of the comment period.
3646	1	calarkin45@gmail.com	N/A	The lower Snake R. dams generate over 1,000 megawatts of affordable, carbon-free, baseload electricity that allows for the addition of renewables and is critical in minimizing brownouts and blackouts. Replacing the dams with natural gas plants would cost $200 million annually and add 3 million metric tons of carbon/year to atmosphere. The increase in truck and train traffic would increase CO2 by more than 1.2 million tons/yr. Hundreds of farmers would be impacted by higher transportation costs, meaning either bankruptcy or the need for millions of dollars in government subsidies.	The EIS finds, consistent with this comment, that Multiple Objective (MO) Alternative 3 (including breaching of the four lower Snake River dams) would result in increased emissions and higher regional electricity prices. The EIS analysis shows that MO3 would raise emissions by between 0.12 to 0.16 million tons/year from increased truck and rail transportation, which is lower than suggested in the comment. Under MO3, increased transportation costs would adversely affect farmers, which is consistent with the findings of the EIS.
3649	1	hayden.mary.k@gmail.com	N/A	Many had trouble getting through on the hearings by phone. We're in a pandemic...give more time for comments, please!	We are sorry you had technical difficulties. We are glad to see you were able to provided comments into the online form or through mail. The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate as per NEPA regulations. The CRSO website reminded the public on April 9, that they should plan to submit comments by the close of the comment period.
3651	1	chucksnodgrass@surewest.net	N/A	I support higher spill levels and the resulting higher power costs only if scientific analyses clearly show a meaningful benefit to ESA-listed species and other specific mitigations are approved and funded to replace and pay for the loss of carbon free power generation with equal solar, wind and battery alternatives. In addition, any mitigation plan must include funding for alternative tourism activities such as extensive paved bike trails with parking and rest/picnic areas to help replace lost tourism revenue.	The EIS analysis shows that power reliability can be replaced by adding renewable energy and storage, but the existing fossil-fuel generating plants in the region might increase generation as well, therefore resulting in a net increase in GHG emissions. The Preferred Alternative would not diminish tourism or passive recreation, and therefore mitigation is not proposed. The Preferred Alternative analysis does demonstrate benefits to ESA-listed species.
3656	1	Jennifer Joly	Oregon Municipal Electric Utilities Association (OMEU)	As noted in the DEIS, the breaching of the dams would more than double the regions risk of power shortages. The most recent assessment by the Northwest Power and Conservation Council (NWPCC) is that our power supply is likely to become inadequate by 2021 due to the planned retirement of 1,619 megawatts of coal-fired generating capacity. By 2026, the NWPCC assessment notes that the shortfall will grow to 17%. In light of these existing resource adequacy concerns, we must avoid exacerbating the problem by breaching the Lower Snake River dams, which account for 1,100 aMWenough to power 800,000 homes! Losing these dams and replacing them with carbon-free power would raise BPAs power supply rates by 50%. For OMEU members, whose costs are primarily BPA-related, that would translate to rate increases in excess of 25% for our customers.	Breaching the four lower Snake River dams was evaluated in Multiple Objective 3 but was not included in the Preferred Alternative identified in the EIS. The comments that breaching the four lower Snake River dams would (a) increase the frequency of power shortages (unless and until replacement resources are acquired), and (b) would result in increased costs in the region, are both consistent with EIS findings. The EIS also discusses that Bonneville customers, such as municipal electric cooperatives mentioned by the commenter, may have larger increases in rate pressures than other regional utilities that do not purchase power directly from Bonneville. For Bonneville's wholesale power rates, the Preferred Alternative places additional rate pressure of 2.7 percent relative to the No Action Alternative consistent with the statement in the comment regarding increased rates. These estimates compare the Preferred Alternative to the No Action Alternative, which is not the same as comparing the Preferred Alternative to current operations. Consequently, the estimates are not a comparison to the BP-20 wholesale power rates, which were set assuming the financial impact of the 2019-2021 Spill Operation Agreement and therefore already include a substantial portion of the cost pressures found in the Preferred Alternative. The remaining rate pressure associated with the Preferred Alternative falls within a level that Bonneville has historically been able to mitigate through the costs it has significant control.
3656	2	Jennifer Joly	Oregon Municipal Electric Utilities Association (OMEU)	One of the key features of the preferred alternative is its flexibility to adapt to changing conditions and permit adjustments as more data becomes available. In light of the Action Agencies support for higher levels of spill as part of the Preferred Alternative, we anticipate that operations will need to be recalibrated as more evidence comes in regarding fish survival rates with spill operations at up to 125% total dissolved gas (TDG).	Concur. Adaptive management is an important component of the Preferred Alternative. The Preferred Alternative includes a robust monitoring plan to help narrow the uncertainty between the biological models and will help determine how effective increased spill can be in increasing salmon and steelhead returns to the Columbia Basin. The effectiveness of the spill program will be monitored.
3656	3	Jennifer Joly	Oregon Municipal Electric Utilities Association (OMEU)	The Action Agencies should also examine the Comparative Survival Study (CSS) model assumptions around harvest rates. Depending on the findings about the models predictions, spill operations may also need to be re-evaluated on those grounds. We must have confidence that spill operations clearly benefit the ESA-listed species.	The two models used in the anadromous fish analysis predicted different long-term survival benefits for ESA-listed species. However both models assume that current levels of harvest will continue into the future and are calibrated using the current variable harvest rates, which vary based on predicted run size. To address the uncertainty highlighted by the differing model results, the Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or TDG-related impacts on juvenile migrants.
3656	4	Jennifer Joly	Oregon Municipal Electric Utilities Association (OMEU)	Finally, we suggest that efforts be made to address avian predation as part of the future Columbia River System Operations. As noted in a May 2019 report by the Independent Scientific Advisory Board (ISAB) to the NWPCC, large numbers of colonial, piscivorous water birds, such as Caspian terns and double-crested cormorants, nest in the Columbia River Basin and are believed to be one the greatest sources of mortalityif not the single-greatest sourcefor emigrating juvenile steelhead and yearling Chinook salmon from the upper Columbia and Snake Rivers. Our ratepayers have made significant investments in fish passage at the dams. Future efforts should also be focused on addressing other pieces of this complex puzzle, including avian control.	The co-lead agencies legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. The Preferred Alternative includes a large suite of predation mitigation measures, some of which include maintaining avian wires in the tailrace of lower Columbia and Snake River dams, active hazing of gulls at the dams, and the pattern of operating the spillway gates all mitigate for predation at the dams by birds and fish. The Predator Disruption Operations will mitigate Caspian Tern predation on juvenile salmon and steelhead in the lower Columbia Rivers. Management efforts are ongoing to reduce salmonid consumption by terns in the lower Columbia River, and similar efforts are in progress to reduce the nesting population of Double-crested cormorants in the estuary.
3663	1	a2antoville@gmail.com	N/A	Please note- The comment period was insufficient. 45-days is woefully inadequate to review a plan of this complexity and many people had trouble getting through on the phone hearings.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period. To encourage the highest possible participation, six phone-in opportunities where available to submit comments. The agencies' announcements for the teleconferences included technical assistance instructions for callers who experienced difficulties joining or during a call. The agencies' technical team worked with the AT&T operators to track any concerns heard from anyone who encountered issues joining the calls; no related technical issues were reported. All comment methods were promoted alongside all teleconference information so those unable to participate in a call or who preferred other methods could refer to those comment options.
3666	1	vectorfins@gmail.com	N/A	Dear representatives of The People. Please lengthen the comment period for the dam removal on the Snake River. We a fighting a battle that no one expected and you cannot in good conscious end the comment period at this time.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate as per NEPA regulations. The CRSO website reminded the public on April 9, that they should plan to submit comments by the close of the comment period..
3674	1	W. Marc Farmer	Clatskanie People's Utility District	Multiple Objective Alternative 3 (MO3), which evaluates the effects of breaching the four lower Snake River dams, fails to meet the DEISs multiple objectives and would have additional negative economic impact to Clatskanie PUDs customers beyond what is evaluated in the DEIS. Among the impacts of MO3, the DEIS evaluation demonstrates that breaching the lower Snake River dams would (1) cost $1 billion per year, if the dams generation is replaced with a carbon-free portfolio such as wind, solar, and batteries, and (2) double the risk of region-wide blackouts. If BPAs public power customers bear those costs similar to how they are distributed today, it would add over ten million dollars to Clatskanie PUDs annual power supply costs. Ninety percent of Clatskanie PUDs retail sales are to industrial customers, and power supply increases like those contemplated by the breaching Page 2 of the lower Snake River dams would be shared by the paper mills we serve. The increased risk of outages would also add to the business uncertainty of operating energy-intensive mill processes. All three of the paper mills we server use an energy-intensive process to produce products in a highly competitive, trade-exposed market. Moreover, they have robust competition from producers of the same products outside the region. The cost	The statements and information presented in this comment regarding increased electricity costs from dam breaching in MO3 are consistent with the findings of the EIS. However, the power shortages as presented are only expected if replacement resources are not acquired. The EIS analyzed retail rate effects for commercial and industrial end users, identifying retail rate pressure increases as described in Section 3.7.3.5, Social and Economic Effects of Changes in Power and Transmission in the Draft EIS. The comment that increasing electricity rates will cause job losses and economic risk to communities is consistent with the findings of the EIS. The Draft EIS used the IMPLAN model to assess potential effects to regional businesses. IMPLAN aggregates all economic output and employment, so the EIS was unable to evaluate effects on specific businesses. Although the EIS examined economic effects at the county level, it acknowledges that localized effects of rate increases may be more pronounced as described in 3.7.3.5, Summary of Effects in the Draft EIS. Specifically, customers of utilities receiving power from Bonneville would experience greater upward rate pressure. Clatskanie PUDs customers would see larger rate impacts than the region-wide average. The financial responsibility for fish mitigation is not solely allocated to Bonneville's power ratepayers as the comment suggests. Fish mitigation costs are assigned to each authorized project purpose based on each purposes overall share of project costs, as determined by the cost allocation, by recovering those costs through power rates. Bonneville is required to pay for its share of mitigation costs based on the existing cost allocation. Congress also granted Bonneville discretion to fund the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				pressures and business uncertainty associated with breaching the lower Snake River dams erodes the advantages our region has in reliable, clean, and costeffective power supply and may result in the unintended shifting of trade-exposed industries to other regions. The Wauna paper mill is the largest employer in our service territory and accounts for sixty-five percent of our total retail load. Clatskanie PUD and the communities we serve are highly sensitive to mill operations. From a purely rate-setting perspective, we have estimated that the shuttering of the three mills we serve would result in an immediate doubling of our commercial and residential rates. Doubling our customers electric bills at the same time as the largest employer in the community closes would be devastating. Such economic risk to our community was not evaluated in the DEIS, and we hope the federal decision-makers consider the risk of unintended consequences when evaluating the alternatives. Any new costs resulting from the governments process should be equitably and broadly allocated rather than being borne exclusively by BPAs public power customers. To the extent the preferred alternative results in additional costs, it is time to find ways to more broadly share these regional costs. Not only is it appropriate to equitably align cost responsibility with public benefits, but doing so also recognizes the regions shared stake in both fish recovery and the financial health of BPA. The economic, environmental, and operational benefits of the Federal Columbia River Power System (FCRPS) as it exists today should be properly considered and accounted for.	power share directly to the Corps and Reclamation as part of the Energy Policy Act of 1992, in some situations, including the Columbia River Fish Mitigation program. (Energy Policy Act of 1992, Pub. L No. 102-486, 2406, 106 Stat. 2776, 3009 (1992) (codified at 16 U.S.C. 839d-1 (2012)). Bonneville generally does not, however, directly pay for the capital costs of fish mitigation structures; instead, it reimburses the U.S. Treasury for the power share of appropriations used to construct the structure. Additionally, as described in Section 3.19 of the EIS and Appendix Q, funding to operate the system comes through multiple mechanisms, including Federal tax dollars appropriated to cover system costs as well as revenue generated from the marketing and sale of hydropower. For power-specific costs, Bonneville typically provides direct funds to both the Corps and Reclamation. For joint related costs, including funding for fish and wildlife mitigation actions, the Corps and Reclamation receive annual congressional appropriations to fund most, if not all, capital investments. Bonneville reimburses the U.S. Treasury for the power share of these appropriations. Once the investment is in place, Bonneville will typically direct fund the power share of the operations and maintenance costs associated with the facility. In addition to congressional appropriations for fish and wildlife and costs directly funded to Corps and Reclamation by Bonneville, the Bonneville Fish and Wildlife Program (which is separate and distinct from direct funding described above) funds hundreds of projects each year to mitigate the impacts of the Federal hydropower system on fish and wildlife. Bonneville began this program to fulfill mandates established by Congress in the Pacific Northwest Electric Power Planning and Conservation Act of 1980 to protect, mitigate, and enhance fish and wildlife affected by the development and operation of the Federal Columbia River Power System (FCRPS). Bonneville uses its authority under 16 U.S.C. 839b(h)(10)(A), to make expenditures to implement its Fish and Wildlife Program. These expenditures provide systemwide funding for actions that also mitigate for the non-power purposes of the CRS, so Bonneville recoups the non-power share of those expenditures from the U.S. Treasury as credit, as required under 16 U.S.C. 839b(h)(10)(C). Bonneville's Fish and Wildlife Program expenditures incurred mitigating the CRS operations identified in the Final EIS and adopted in Bonneville's Mitigation Action Plan would continue to be allocated and borne as provided by existing laws governing the FCRPS and the long-standing accounting procedures used to implement them. Moreover, as described in Chapter 7 of the EIS, funding decisions for Bonneville's Fish and Wildlife Program are not being made as part of the CRSO EIS process. Future budget adjustments would be made in coordination with the regional entities that help Bonneville implement its Fish and Wildlife Program. The statement that roughly a quarter of costs from Bonneville's power rates are due to fish and wildlife spending is consistent with information provided in the EIS.
3674	2	W. Marc Farmer	Clatskanie People's Utility District	Hydropower is a clean, renewable resource with high availability that is vital to meeting the regions carbon goals, which continue to become more demanding as societys concerns about carbon intensify. A recent study published in the Proceedings of the National Academy of Sciences (PNAS) concluded that BPAs hydropower-based system can be largely attributed with the Pacific Northwest regions production and use of the cleanest energy in the nation, leading among the countrys 20 largest electric regions. FCRPS hydropower is also a flexible resource that enables the region to meet future sustainability goals by integrating intermittent renewable resources like wind and solar onto the grid. The value and demand for the flexible capacity that the FCRPS provides will only increase as state legislation and policies drive the retirement of fossil fueled baseload resources and replace them with intermittent renewable generation. Page 3 The FCRPS projects are a key part of reliable and affordable grid operations and cannot be replaced at low cost by intermittent renewable resources. The value of capacity and reliability of the power produced by these projects has to be properly accounted for.	The information provided in the comment regarding the importance of hydropower for regional power reliability, greenhouse gas emissions goals, and the integration of variable renewables is consistent with the findings of the EIS. Regarding valuing capacity and reliability, the EIS analyzed the value of the replacement resources needed to maintain power system reliability as well as the flexibility and ramping capability of the four lower Snake River dams in the sensitivity analyses Section 3.7.3.5, Potential Replacement Resources and Associated Costs in the Draft EIS. The Preferred Alternative expects the power reliability objective to be met and upward rate pressure is expected to be minor relative to the No Action Alternative.
3689	1	jessica@necoalition.org	N/A	This comment period during a pandemic is not long enough so extend it.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period.
3690	1	joosgalefamily@comcast.net	N/A	Finally, I'd like to express my strong dismay regarding the insufficient comment period. 45-days is woefully inadequate to review a plan of this complexity and many people had trouble getting through on the phone hearings.	The co-lead agencies considered requests to extend the public comment period. This NEPA process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO EIS website was updated to inform the public that they should plan to submit comments by the close of the comment period. To encourage the highest possible participation, six phone-in opportunities where available to submit comments. The agencies' announcements for the teleconferences included technical assistance instructions for callers who experienced difficulties joining or during a call. The agencies' technical team worked with the AT&T operators to track any concerns heard from anyone who encountered issues joining the calls; no related technical issues were reported. All comment methods were promoted alongside all teleconference information so those unable to participate in a call or who preferred other methods could refer to those comment options.
3716	1	N/A	N/A	The DEIS should consider another option to breach the four lower Snake River dams and utilize spill at the Columbia River dams to 125% TDG. This results in the best scenario for salmon recovery.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The co-lead agencies are required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. The agencies disagree that an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is reasonable, and thus was not proposed as an alternative given the unacceptable risks to public safety from such an alternative. For Power and Transmission, MO3 and Multiple Objective alternative 4 (MO4), individually each caused large loss-of-load probability (LOLP) results (e.g., increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning (1,000 aMW is about the average amount of power consumed by Seattle City Light). As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination of MO3 and MO4 has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of MO3 and MO4 individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, those replacement resources would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire U.S. by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. This potential alternative has not been evaluated for direct, indirect and cumulative effects to other resources. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and was not proposed as an alternative. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
3717	1	holdercarl@hotmail.com	N/A	Scientists reported the alarming conclusions of 12 years of study, 2008-2019. Fish-eating birds, including Caspian terns, double-crested cormorants, and gulls, are killing half, or more, of the juvenile salmon and steelhead during their annual outmigration down the Columbia River to the Pacific Ocean. Billions of dollars in actual local and federal dollars + the at least 1,000 MWe energy is lost due to fish rules. Inconceivable that there is no control of fish-eating birds that provide absolutely no benefit. The distruction of salmon due to flocks of birds is allowed to continue only due to absurd agency rules A couple of coyote mating pairs or a family of Texas feral hogs on the islands would solve the bird problem with very little cost, no environmental damage, and no PETA outrage. Control the birds with natural predators.	The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids. Specifically for the comment on predation, on-going actions described in the No Action Alternative to reduce predation on migrating fish are included in the Preferred Alternative. In addition, water management actions ("Predator Disruption Operations" measure) in the John Day reservoir is expected to further reduce avian predation on migrating juvenile fish.
3726	1	emiliecynthia@gmail.com	N/A	The comment period was insufficient. 45-days is woefully inadequate to review a plan of this complexity and many people had trouble getting through on the phone hearings.	The co-lead agencies considered requests to extend the public comment period. This National Environmental Policy Act (NEPA) process included a wide array of cooperating agencies whose close involvement throughout the process allowed the co-lead agencies to incorporate feedback. Given the broad range of comments received and the extensive Federal and non-Federal participation in the overall process as well as the level of public engagement in the six virtual public meetings in the region, the co-lead agencies determined that an extension was not warranted and that the 45-day public comment period was adequate consistent with NEPA regulations. On April 9, the CRSO website was updated to inform the public that they should plan to submit comments by the close of the comment period.
3726	2	emiliecynthia@gmail.com	N/A	The Agencies preferred alternative is a huge waste of public resources and perpetuates the status quo which has been rejected 5 times by a federal court over the last 25 years. An Alternative Plan must focus on three things: (1) Removal of four obsolete Snake River Dams, (2) increased flows over Columbia River Dams, and (3) habitat restoration. Persecution of native predator species must be eliminated from this plan.	The co-lead agencies are required to evaluate a reasonable range of alternatives in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinions from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets most other EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3 by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Similarly, the agencies did not identify Multiple Objective alternative 4 (MO4), which includes a measure to draw down the four lower Snake River and four lower Columbia River projects because of its adverse impacts to resident fish power generation, irrigation and greenhouse gas (GHG) emissions. One major change that the Preferred Alternative represents is a new spill operation (flexible spill) to increase spill when the projected value of power is relatively low, pass higher proportions of juvenile fish through the spillway, and spill less water for limited durations when the projected value of power is relatively higher (e.g., during peak power demand). The flexible spill operation creates an opportunity for salmon and steelhead to avoid going through the power house which may adversely effect fish and improve travel time for migration through the system. The flexible spill operation in the Preferred Alternative would be implemented through an adaptive framework that allows the co-lead agencies to adjust operations as new information emerges. As part of the flexible spill operation, planned spill would increase up to 125 percent total dissolved gas levels at some projects. The Preferred Alternative also contains measures to benefit resident fish, as well as lamprey, while

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					providing reliable flood risk management, water supply for irrigation, and flexibility in hydropower generation that would be valuable for integrating wind and solar energy. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The Preferred Alternative identified in the Draft EIS will continue many ongoing actions that are detailed in Section 7.6.4.1. These actions include ongoing efforts that provide for habitat restoration and predator management. Examples of some of these actions are included in Table 7-5.
3732	1	reputnam@gmail.com	N/A	Chapter 7.2 says: BEGIN QUOTE (slightly edited for brevity) The co-lead agencies determined that the No Action Alternative, MO1, MO2, and MO4 allow for the operation of the projects (meaning dams) in furtherance of all of the congressionally authorized purposes to varying degrees. Alternative MO3 would not meet the congressionally authorized purposes of operating and maintaining the four lower Snake River dams for navigation, hydropower, recreation, and irrigation. New congressional authority through new laws and associated funding would be required to implement dam breaching measures. END QUOTE So to summarize what I just read, the three agencies, do one thing. The build and maintain dams. That is their life. That is their congressional authorization (MAGIC WORDS). If you want to remove the dams, go get Congress to authorize that and get some money, because it will not happen with the local Corp of Engineers, or BPA, or Bureau of Reclamation. Thats their story, but it is totally wrong. Those magic words: congressional authorization are a smoke screen by the local lead agencies to make us believe that they cant take out the dams. In fact, they could do that very thing without additional congressional authorization. It doesnt take congress to decommission a Navy ship, like it didnt take Congressional action for the Portland Corp of Engineers to decommission the Willamette Lock and Dam in Portland. Its part of what they are responsible for.	The commenter's assertions are incorrect. If MO3 were selected, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the four lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions is required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. More information is available in the Corps Engineering Regulation (ER) 1165-2-119 Water Resources Policies and Authorities, Modifications to Completed Projects (Sept. 20, 1982) or ER 1105-2- 100, Appendix G, Section III Post Authorization Changes. Regarding Willamette Falls Locks (this Corps navigation project does not include a Dam), the commenter is mistaken. The Corps has administrative discretion to (1) place the locks in a minimal maintenance caretaker status, on account of lack of funding associated with a decline in commercial tonnage through the locks, and (2) close the locks to vessel traffic, due to life safety concerns associated with unsafe physical conditions. In contrast, the Corps lacks authority to deauthorize the project for its navigation purpose or dispose of the land and improvements prior to such deauthorization. Only Congress can deauthorize the project. The Corps has evaluated the feasibility of deauthorization and disposal, and understands that congressional committees are considering whether to include such a deauthorization in the next Water Resources Development Act (or WRDA). As such, the Corps administratively closing the locks to vessel traffic due to life safety concerns is quite different than Congress legislatively deauthorizing the project and directing disposal.
3734	1	reputnam@gmail.com	N/A	Why did you not use a third-party organization such as Mitre to help evaluate the various options (alternatives) in order to generate an objective solution instead of keeping the decision "in-house". By not outsourcing the analysis you have put the agencies in the position of being totally biased regarding the "preferred alternative". I would think that this puts the lead organizations legally at risk.	The co-lead agencies used a multi-agency, multi-disciplinary and science-based approach to analyze the alternatives in the EIS. The co-lead agencies invited a number of entities (including tribes, states, and agencies) from across the region to participate in the EIS process as Cooperating Agencies, and over 30 of those invited agreed to participate. Staff from the Cooperating Agencies joined the technical teams and provided their expertise and review of the development and analysis of the alternatives. Leaders from the co-lead agencies met with tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have the responsibilities on behalf of their agencies and the public to undertake the National Environmental Policy Act (NEPA) process, comply with other Federal laws and regulations, and propose recommendations regarding future operation, maintenance, and configuration of the dams within the authorities provided by Congress for the CRS system. NEPA does not require a third party to evaluate the alternatives or to propose a specific solution, these are the responsibilities of the co-lead agencies. The co-lead agencies selected senior staff from across the country with expertise in their fields to serve on the EIS team. The Draft EIS was subjected to two internal agency reviews by the Corps of Engineers from other experts not involved in the development of the document. Additionally, the entire document, analysis, and modeling were reviewed following an Independent External Peer Review (IEPR) process that meets the Office of Management and Budget (OMB) circular on peer review requirements under the "Information Quality Act" and the Final Information Quality Bulletin for Peer Review by OMB (referred to as the "OMB Peer Review Bulletin). It also meets guidance for the implementation of both Sections 2034 and 2035 of the Water Resources Development Act (WRDA) of 2007 (Public Law (P.L.) 110-114) and standards of the National Academy of Sciences independent peer review. The final IEPR report will be publicly available. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative meets the EIS objectives for anadromous and resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse impacts to communities and the economy. Consistent with the twin aims of NEPA, the co-lead agencies disclosed the impacts of their action to the public and will use the input from the public to make an informed decision when the Preferred Alternative is selected.
3736	1	reputnam@gmail.com	N/A	Several sentences from the draft EIS make it appear that many organizations came together to work on this EIS. One such sentence is from the Preface: "More than 30 entities from across the region, consisting of tribes, Federal agencies, and state and local governments, agreed to participate as cooperating agencies in this NEPA process." However another sentence from the draft EIS is quite troubling: " ..., the co-lead agencies identified a Preferred Alternative..." I could find no information that said that after the three co-lead government organizations picked "the final solution" that it was accepted and approved by each of the 30 entities that originally participated. Was there a vote, or other form of acceptance by each of the 30 organizations, or was the final alternative just decided by the three lead organizations. If the other organizations did not have a significant voice, then this EIS is flawed.	The co-lead agencies invited a number of entities (including Tribes, states, and agencies) from across the region to participate in the EIS process as cooperating agencies, and over 30 of those invited agreed to participate. Staff from the cooperating agencies joined the technical teams and provided their expertise and review to the development and analysis of the alternatives. Leaders from the co-lead agencies met with Tribal leaders for formal consultation, and with other organizations and stakeholders to have dialogue and receive feedback as the EIS progressed. However, only the co-lead agencies have authority to make decisions regarding future operation and configuration of the dams in the CRS. The cooperating agencies reserved their rights to submit comments on the Draft EIS and Final EIS, and their acceptance of the cooperating agency invitation did not require that they concur in the co-lead agencies' identification of the Preferred Alternative.
3813	1	hstebbings@shavertransportation.com	Shaver Transportation Company	Much of the impact on salmon populations remains outside of the scope of the Columbia River System operations. The draft DEIS correctly recognizes this and calls for further action to accelerate the recovery of anadromous fish like salmon. The most updated science from the National Oceanic and Atmospheric Administration finds that conditions in ocean waters need to improve for fish numbers to increase, and that dam breaching would yield only marginal and uncertain improvements to fish populations while devasting the regional economy. We need to instead consider factors impacting the whole ecosystem that salmon depend on and not limit our focus to the dams on the Columbia Snake River System, where so much investment and improvement has been made in fish passage infrastructure.	The co-lead agencies recognize that there are many effects to salmon and steelhead populations outside those associated with the operation, maintenance and configuration of the dams, including ocean conditions. A whole ecosystem approach would be welcomed by the co-lead agencies, who will be active participants in regional discussions and solutions for achieving broader recovery objectives. While none of the alternatives would affect ocean conditions, the co-lead agencies recognize that these conditions are a major driver for adult returns and that numerous studies have shown the importance of this environment in the return of adult salmon and steelhead (Peterson et al. 2019). As such, two of the models used in these analyses, CSS and NMFS Lifecycle model, use metrics of ocean productivity to predict adult returns. These metrics can be seen at: https://www.nwfsc.noaa.gov/research/divisions/fe/estuarine/oeip/g-forecast.cfm.
3813	2	hstebbings@shavertransportation.com	Shaver Transportation Company	Our four-barge tows move grain from as far inland as Lewiston, Idaho and carry the equivalent of one and a half unit trains or 538 semi-trucks. Each year, barging on the 365-mile inland Columbia Snake River System keeps the equivalent of 334,615 trucks or 870,000 rail cars from moving through the sensitive airshed of the Columbia River gorge. On the Snake River alone, barging keeps 35,140 rail cars or 135,000 semi-trucks from moving on our already congested transportation system each year. Barging also keeps transportation costs in check by offering an alternative to rail and trucking. Without barging, the regional agricultural community would be captive shippers and see significant impacts. More than 1,100 farms would be at risk of bankruptcy, and grain suppliers and shippers would likely see an increase in transportation and storage costs by 50-100%. Our highway, rail and grain elevator networks would need over $1.1 billion in capital investments to adapt to the loss of barging. This includes hundreds of miles of short-line rail track that have been abandoned, as well as new rail, major highway improvements and retrofits for grain elevators that do not have rail-loading capabilities.	The EIS evaluates potential effects on farmers associated with increased transportation costs under MO3 in Section 3.10.3.5. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. The cost increases to specific shippers would depend upon location and would vary throughout the region, depending on transportation options at each location. Generally, those grain shippers that are the farthest from alternate shipping locations (shuttle rail facilities or river ports on the Columbia River) would be the most adversely affected. The EIS recognizes that there is no guarantee wheat grown in the Northwest would be competitive now or in the future because there are many factors that influence international commodity markets (e.g., trade agreements, the U.S. dollar, global supply, etc.). However, the analysis finds that the cost to transport wheat to market would continue to be lower than costs paid by other wheat growers in the United States (e.g., the Dakotas and Midwest). Favorable conditions for Northwest wheat growers that help them stay competitive are: (1) the natural environment of the Palouse region (weather, soils) is ideal for growing this type of wheat, which leads to some of the highest yields per acre in the world, and (2) proximity of Northwest export ports.
3830	1	dmoorx@gmail.com	N/A	I have attached a letter commenting below in attachments	Unfortunately, an attachment was not received from the commenter. The co-lead agencies requested the commenter resubmit via e-mail on June 25, 2020; however, the co-lead agencies did not receive a response to this request.
3836	1	bobkerslake@msn.com	N/A	Lowering Lake Pend Oreilles summer lake level in low water years, thus eliminating our long understood stable summer lake elevations, would devastate our local economy, which is predominantly dependent on water-based recreation. This change would have prevented boat access to countless locations around the lake, preventing close to 90% of waterfront landowners from mooring their boats, destroyed property values, and crippled the summer property. Lowering the summer lake level would make my waterfront unusable. My dock would rest in the mud and it would be impossible to dock my boat. My families very significant investment into the property would be destroyed. I would be forced to sell the property. All the business and revenue my family and friends bring to Bonner County would be lost forever. I am sure many other property owners would be forced into the same decision. It is our understanding this draft preferred alternative could still be altered during this process, in which case, we want to emphasize again that we strongly appose any future operational changes that would lower, shorten, or provide uncertainty to Lake Pend Oreille summer lake levels.	No effects to Lake Pend Oreille elevations that would affect boat ramps are anticipated under any alternative in normal or high water years. Under Multiple Objective alternative 4 (MO4) in low-water years only, water surface elevations at Lake Pend Oreille (Albeni Falls) may be 1 to 3 feet lower between July and September relative to the No Action Alternative. While the analysis does not detect changes in boat ramp accessibility from these changes in water levels at Federal- and state-managed boat ramps, the EIS acknowledges that major adverse effects to recreational activities associated with impaired lake aesthetics (e.g., exposed mud flats) and reduced functionality of fixed docks and other infrastructure are possible under MO4 in low-water years. Moreover, under the Preferred Alternative small changes in river flows and reservoir elevations at Hungry Horse Dam are not anticipated to affect recreation at its reservoir or affect downstream reaches including the Pend Oreille Lake and River.
3841	1	twolinkers1960@gmail.com	N/A	It has also been established that water behind Columbia River dams is warmer than is safe to the survival of salmon and steelhead, which have been shown to struggle in water temperatures higher than a maximum of 64 degrees. The colder water of the upper reaches of the river provides sanctuary for salmon as the climate changes and warms. If this cooler water flows freely down the river, it will mitigate some of the changes brought by climate change.	The Draft EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives' effects on Snake River stocks, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Regarding climate change, the climate science community is still developing models to the resolution required (river-scale vs. global- or regional-scale) to analyze possible effects to water temperature from climate change. It was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature as discussed in Section 4.2.3. Regarding water temperatures under dam breach scenarios, the analysis of MO3, which includes breaching the four lower Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action Alternative conditions in the Snake River. However, even with the four lower Snake River dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The models showed minor changes in the Columbia River under the dam breach scenario alternative.
3848	1	N/A	N/A	It is time to remove the earthen portions of these dams. The material can be stockpiled. If after twenty years there is no improvement in the fish populations then rebuild the dams.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets most other EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The commenter's suggestion to stockpile and rebuild the dams if breaching did not result in meeting the anadromous fish objectives of the EIS would have to be studied and effects evaluated. Siting locations for materials of this amount for long term storage and new construction costs to rebuild would be part of that analysis. The alternative suggested by the commenter would include the adverse effects of implementing MO3, and potentially irretrievable losses to communities and economy. Therefore, the co-lead agencies do not consider this to be a reasonable variation of MO3, which included breaching the four lower Snake River dams.
3851	1	N/A	N/A	To save the endangered Snake River salmon, Southern Resident orcas and ratepayers money, the federal agencies need to address the Columbia River System in a two-tiered process. Tier one is an emergency response action for the immediate drawdown and breach of Lower Granite and Little Goose dam, followed by the remaining two dams in subsequent years. Tier two is addressing system operations and further mitigation activities in the rest of the Columbia River Basin using the new EIS, assuming that the four lower Snake River dams.	The Draft EIS evaluated under MO3 which included the measure to breach the four lower Snake River dams (referenced as tier one in the comment) including operations (referenced as tier two in the comment) of the other ten Federal dams in the CRS and mitigation for effects to resources from implementing this alternative. If MO3 were selected, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					Also, under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not require the co-lead agencies to take affirmative actions to support recovery of ESA-listed species. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA-listed species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats.
3856	1	dfarrellseidler@gmail.com	N/A	Salmon are vital cultural staples for indigenous people and locals of the Pacific Northwest as well as a highly valuable food source. Since their construction dams have decimated salmon populations. The removal of the Snake river dams has been supported by scientists. In addition, for over two decades, Tribal, federal, state and independent research has repeatedly corroborated this determination. The endangered southern resident orcas rely on chinook salmon for 80% of their diet. The Snake river supports 70% of the Chinook salmon within the Columbia River Basin. In total the dams provide 5-13% of hydroelectric power. In 2017 it was predicted that removing the four lower snake river dams would double if not triple salmon populations. The lower snake river dams also cost $312.9 million dollars a year to maintain. While there is the short term loss of employment for workers, there will be a long term economic benefit. The 2020 draft EIS fails to accurately address the need for dam removal promoted by numerous advocates, scientists, and concerned locals. The first priority needs to be salmon survival and while that might mean paying a short term economic price, it will be well worth it. The best option for the survival of salmon populations is to remove these four dams. The Draft EIS itself acknowledges that restoring the river will be more beneficial to the endangered Snake River fish populations than any other option considered or analyzed. This restoration will be the most effective if the four dams are removed. Thus, dam removal should be included as a foundational element of the Preferred Alternative I suggest EIS recommend that the federal government (congress) approve the dam removal and subsidize the workers who have been laid off due to the dam removal until they can find alternate employment. This EIS draft should be adjusted accordingly by presenting the removal of the four snake river dams as the preferred alternative.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing SARs from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse negative unintended consequences, such as long delays of adult migrants, or total dissolved gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The final EIS in Vegetation, Wetlands, Wildlife, and Floodplains (Section 3..6.2.6 and Table 3-102), and Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and the potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). Moreover, NMFS concluded in its 2020 CRS BiOp that operations, maintenance and configuration of the CRS is not likely to adversely affect SRKW. he EIS describes the operational characteristics of the four lower Snake River dams in Section 3.7.3.5 Lower Snake River Full Replacement (Used in Rate Sensitivity Analysis). While the comment is correct that the four lower Snake River dams account for a small portion of total regional power generation, they are a larger portion of the Federal Columbia River Power System (FCRPS), from which Bonneville markets power. They also have unparalleled ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to 2,300 MW of capability in certain months of the year. See draft EIS, Table 3-160. The ramping capability is valuable for system balancing, which is used to serve load (consumed energy by houses, business, and industry) and to balance out the variability that renewable generation causes to the system. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. the Preferred Alternative also meets most other EIS objectives for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
3858	1	kairos42@earthlink.net	N/A	The attached technical paper by two retired Corps employees with service at Walla Walla District and others clearly show the peaking, ramping, balancing and reserve claims of $996 million per year are an almost complete fabrication. Using this number is a fatal flaw in the development of the Preferred Alternative rendering the DEIS unusable.	The peaking, ramping, balancing reserve, and contingency reserve values quoted in the EIS are derived from historical data at the hydropower projects. As an example, Table 3-160 at page 3-907 in the Draft EIS shows the historical sustained ramping capability for the four lower Snake River projects. When flows are insufficient for all turbines to operate full time, the four lower Snake River projects generally operate at a lower generation level for most of the day, but are able to ramp up to provide higher generation levels to help meet demand during the highest-load hours. These dams provide over 1,000 MW of carbon-free energy (serving roughly 10% of Bonneville's load or about the amount of energy used by Seattle City Light) and up to 2,000 MW of sustained peaking capacity at certain times of the year. The dams also have unparalleled ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 MW to approximately 2,3000 of capability in certain months of the year. See EIS, Section 3.7.3.5, Lower Snake River Full Replacement, pages 3-905-907 of the Draft EIS. The costs of replacement resources are from the Northwest Power and Conservation Councils Seventh Power plan and Mid-Term update. Details of the methodology are described in Section 3.7 of the EIS and in Appendix J.
3867	1	rgkiyokawa@gmail.com	N/A	In the MO2, I was wondering how transporting collected ESA-listed juvenile fish with barges and trucks affect the fish and the environment. In the same alternative, the draft states that there would be more hydropower created, however, do we really need more power? The cliffs of the Columbia River are inundated with thousands of windmills, which often are left idle because of the excess energy the dams provide. The CRSO EIS website states that the Bonneville Dam has a, total generating capacity of over 1,200 megawatts - enough to power 900,000 homes.	The comment asks if we really need more power. Yes, at certain times of the year and in certain water conditions. Currently, as modeled in the No Action Alternative, the region faces power shortages in about one in every fifteen years, with the highest risk of power shortages in the winter. See Section 3.7.3.2 and Appendix J, Section 4.1.2.1. With the retirement of coal plants in the region, the need for power would increase in the coming years. The comment describes the curtailment of renewable power when there is excess power generation on the grid. This is not a frequent occurrence. The EIS analyzed potential curtailment of renewable power using the GridView model and describes the changes under each alternative in Appendix H, Section 3.1.1. The EIS finds that renewable curtailment does increase under Multiple Objective alternative 2 (MO 2); however, it represents a small portion of the increased hydropower in that alternative. The Bonneville Dam has a total capacity of 1,195 MW and generates 554 aMW in an average water year as described Section 3.7.2.1, Power Generation, Table 3-110 in the draft EIS. The generation of the Bonneville Dam, assuming average consumption of 11 megawatt hours per year, would be enough to power 450,000 homes, if the dam generated at its full capacity all of the time this would be enough power for 900,000 homes consistent with the statement in the comment. Section 3.5.3.3 provides a description of transportation related activities that are in the No Action Alternative. Related to the effects of transportation on fish, both of the fish models account for the number of fish transported and when they are transported. The two models have different predicted responses based on expected benefits of transport compared to migrating in-river under the various river management scenarios. The predicted outcomes for each fish metric presented in Chapters 3 and 7 include the expected response to variations in transportation rates.
3867	2	rgkiyokawa@gmail.com	N/A	I agree that the MO3 would not be the most preferred action by breaching the dams. It is clear in the report that it would be detrimental to the economy if we did so. I do think hydropower and other renewables are very important for our journey off of fossil fuels and natural gas, but what about taking one or two dams out and seeing how that goes? There are smaller dams along the Snake River that would still benefit the fish populations if taken out.	The four lower Snake River dams were jointly authorized and function together as a system with the other ten projects analyzed in this EIS; having only two out of the four dams functioning would not allow the co-lead agencies to meet navigation, greenhouse gas, or power reliability objectives, while also not likely making a substantial change for migrating salmon in the Snake River based on analysis of breaching all four projects and in comparison to other alternatives. The Draft EIS examined the operation and maintenance of the 14 projects in the Columbia River System. Other dams are not within the scope of the EIS or the purview of the co-lead agencies.
3867	3	rgkiyokawa@gmail.com	N/A	My biggest concern about the DEIS is that it doesnt talk about the sea lions that have affected the populations very negatively. I understand that this statement focuses on the dams, however, the sea lions gather up in the pool near Bonneville Dam and over consume fish. I believe there needs to be some action against the invasive California Sea Lions to improve the survival of the salmon	The co-lead agencies' legal authorities relate to operating and maintaining the CRS to meet multiple statutory purposes. They are also required to ensure that operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. To comply with the ESA, the co-lead agencies have historically supported actions to mitigate adverse effects to ESA-listed species from CRS operations, through funding, direct implementation, and other means. Under the Preferred Alternative, those actions, including for the purpose of reducing pinniped (sea lion) and avian predation on ESA-listed species, would generally continue to ensure compliance with the ESA. Under the Preferred Alternative, actions that reduce pinniped and avian predation on ESA-listed species, would generally continue to ensure compliance with ESA as described in Section 7.6.4.1, Ongoing Programs, including ongoing measures to haze and monitor pinniped predators. Other entities in the region have authorities and obligations to mitigate the impacts from pinniped and avian predators and the co-lead agencies will continue to work closely with those entities to benefit ESA-listed salmonids.
3867	4	rgkiyokawa@gmail.com	N/A	I also wanted to note that the DEIS addresses the tribes concern appropriately and should keep them as a high priority in the planning.	Tribal input, concerns, interests, and especially treaty rights were considered throughout the Draft EIS analyses and in the formulation of the Preferred Alternative. The co-lead agencies are engaging in government-to-government consultation with the tribes, and several tribes are cooperating agencies on the CRSO EIS.
3882	1	joanneerichter@gmail.com	N/A	The preferred alternative MO4 clearly shows that Federal agencies in charge of Columbia / Snake River dam operations simply want to maintain the status quo: producing power thats largely sold at a loss, from aging infrastructure thats long due for repair, while maintaining warm pools of water behind the dams that are no longer critical for the transport of grain produced by Central Washington farmers. Economic studies have shown that the impacts of breaching or removal of the four lower Snake River Dams can be readily mitigated.	The co-lead agencies note that Multiple Objective alternative 4 (MO4) was not identified as the Preferred Alternative in the Draft EIS. Rather, the Preferred Alternative included measures from various alternatives after consideration of beneficial and adverse effects of various measures. The EIS evaluated beneficial and adverse effects across an array of resource areas including potential effects at the national, regional and local level. The EIS does not employ a cost-benefit framework for decision-making. This is because, consistent with National Environmental Policy Act (NEPA) analysis framework (see 40 C.F.R 1502.23), the beneficial and adverse effects are expressed as a variety of qualitative and quantitative environmental and economic metrics. Consequently, a focus solely on the monetized economic costs and benefits would exclude important tradeoffs associated with the alternatives communicated in the EIS, including effects on fish. Furthermore, the EIS evaluates the performance of the CRSO EIS alternatives with respect to multiple objectives, for example related to improving fish passage and survival, reliable power generation, and minimizing greenhouse gas emissions. Tables 7-1 and 7-55 in Chapter 7 provides a summary of the beneficial and adverse effects of the alternatives, including the quantified social welfare costs and benefits for a subset of the resource areas (specifically, hydropower, navigation, and irrigation) as well as the implementation costs of the alternatives. The EIS finds that under a dam breach scenario, average transportation costs for wheat farmers would increase 10 to 33 percent, but that individual farmers could experience increases that are doubled. Moreover, in the Draft EIS, Table 3-112 on Generation Costs of the Columbia River System Projects, in Section 3.7.2.7 of the draft EIS, lists the average cost of generation in $/MWh for the Columbia River System projects. The four lower Snake River dams generation is well below both Bonneville's Priority Firm Wholesale Power rate and the average market price for wholesale power.

					The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. The spill operation for juvenile fish passage that is included in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The effects of delayed mortality are discussed throughout the EIS analysis for each alternative and current high quality data and the best available scientific information was used for this analysis. Based on analysis by the CSS, SARs associated with population declines (SARs of less than 1%) have the potential to be greatly reduced under the Preferred Alternative, and on average, SARs are expected to be well above 2.0% for Snake River spring Chinook salmon and steelhead. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species.
3882	2	joanneerichter@gmail.com	N/A	A key component of the preferred alternative MO4 is flexible spill, but studies by the Fish Passage Center have clearly shown that this practice is inadequate as a long-term strategy, and does not produce salmon survival benefits that are needed from the Columbia / Snake River dams. The flex spill proposal is not adequate as a long-term solution, and will result in the dangerous decline of salmon and steelhead populations, particularly in light of predicted climate change impacts in the Salmon and Snake River Watersheds. The recovery of Columbia Basin fish species will not occur if the approach recommended in the DEISs preferred alternative is adopted as a long-term strategy.	Multiple Objective alternative 4 (MO4) was not identified in the Draft EIS as the Preferred Alternative and its spill operation was not carried forward in its entirety into the Preferred Alternative. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The Preferred Alternative includes an adaptive management plan. This plan involves working with regional sovereigns to develop a study to assess the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse unintended consequences, such as long delays of adult migrants, or total dissolved gas (TDG)-related mortality of juvenile migrants. Please see Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
3882	3	joanneerichter@gmail.com	N/A	A new comprehensive approach is needed that would recover salmon abundance, invest in farming and fishing communities to sustain their livelihoods, and adopt actions that would support an affordable, reliable, and increasingly decarbonized regional energy system	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The co-lead agencies recognize the desire to continue the conversation across the region about the future of salmon recovery, affordable and reliable clean electricity, increasingly decarbonized regional energy system, tribal perspectives, and economic vitality for the many people who depend on the CRS for their way of life. The co-lead agencies will be active participants in regional discussions and solutions for mitigating the effects of the CRS and achieving broader recovery objectives. The Preferred Alternative for long-term system operations, maintenance and configuration of the CRS presented in the Draft EIS is based on todays conditions and environment. Its also important to note that technology is quickly changing, as is the regions dynamic environment and energy market, and the region needs to consider new information and adaptively manage resources. The co-lead agencies recognize that no matter which alternative in the Draft EIS was identified as the Preferred Alternative, the decision would likely draw criticism from some stakeholders or sovereigns. The region includes stakeholders, sovereigns, and other interested parties with diverse and varied opinions on these very important topics, and many are strong in the belief that their perspective is the best path forward. It is important to keep in mind that factors, both human-caused and natural, that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of fish, and will continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended nor required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. The co-lead agencies look forward to participating in that discussion. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the EIS objectives) as well as the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. The Preferred Alternative is also more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
3962	1	jim@lvenergy.com	N/A	However, we would like to focus our comments on the positive impacts the lower Snake River dams have on global efforts to reduce GHG emissions. Lower Valley Energy is heavily involved in some unique and successful renewable energy and conservation programs. We have one the most successful voluntary green power sales programs in the country. We are also one of the three founding partners with Teton County and the Town of Jackson, Wyoming in an organization called Energy Conservation Works (ECW). ECW has raised millions of dollars to support local residential and commercial energy conservation programs, renewable energy projects, and alternative fuels for vehicles. Because of our commitment to sustainability we recognize the importance of the lower Snake River dams to the region's clean energy goals as outlined in the DEIS. The report shows that if the dams were replaced with natural gas resources, it would add an additional 3.3 million metric tons of CO2 to the region each year. The dams do much more than provide clean energy, they also act as a giant, clean battery that helps us add new renewables to the grid. They store water and release it to generate electricity when needed to fill in the gaps for wind and solar power, keeping the grid in balance. Without the dams, many MWs of wind and solar power would not have been able to be co-located in the region. While we acknowledge the significant effort put into the DEIS, we believe more effort should be invested into studying the benefits the dams provide in reducing GHG and the growing impacts of climate change.	While the commenter suggests that the benefits of the lower Snake River dams are not adequately captured in the EIS, the co-lead agencies sought to provide a balanced analysis of impacts to affected resources. Section 3.8.3.5 of the EIS provides information on the greenhouse gas (GHG) emissions effects of MO3, which includes breaching the four lower Snake River dams. Consistent with this comment, the analysis finds an increase in GHG emissions of 3.3 million metric tons (MMT) CO2 under MO3, if the replacement power resources are natural gas (the least cost replacement). Section 4.2 and Chapter 7 of the EIS discusses how climate change interacts with the alternatives, including the potential combined effect on GHG emissions.
3970	1	Shelley Silbert	Great Old Broads for Wilderness	Your website required us to review 270 megabytes (over 5,000 pages) of information from a website. However, the co-lead agencies made it extremely difficult and limited comments online or by hand-delivery. The filing online is limited to a maximum of 100 kb with no more than 5 attachments of 2 megabytes apiece. It limited pictures, graphs or diagrams to make our point. We have filed comments with many other federal agencies and have never encountered such obstructive difficulties in filing comments. We find this an egregious misuse of the NEPA process that limits public comments in scope and size limit. The one site designated for hand delivery was locked to public access. When our Broad was able to finally use a call box outside, everyone in the building was unaware of the DEIS comment location. We find it completely unacceptable for 3 public agencies to make filing a document so challenging and difficult. We will be sure to bring this to the attention of the Northwest delegation and the judge for this case. Conclusion Regarding the CRSO-DEIS and its Preferred Alternative Overall, the 2020 CRSO-DEIS is a flawed document for several reasons delineated herein. It supports continuation of a failed, incremental, status quo management approach that will not only not recover Snake Basin anadromous fish runs to the needed 4% SAR ratio, but actually includes measures that most likely will expedite the extinction of Snake Basin anadromous fish. In its attempt to "balance" resources/uses in favor of lower Snake nonessential hydropower production, limited freight transportation, and the resolvable issues related to use of one reservoir for irrigation, the Preferred Alternative, in effect, guarantees that Snake Basin anadromous fish will continue to decline in numbers to the point of extinction. The Preferred Alternative does not meet the mandate of the Court and is entirely inadequate to the task of recovering Snake River Basin salmon and steelhead. What these fish need is a free-flowing lower Snake River.	The co-lead agencies are sorry for any technical difficulty experienced. It is accurate that the website had file size limitations that were listed for a single entry. That was not to limit you in your comments, but to alert you to submit in multiple entries or either contact the CRSO info helpline, or mail your materials to the P.O. Box listed on the CRSO website and on other news and informational releases. Hand delivery was not an option for public comments, and unfortunately with the COVID-19 pandemic response, the co-lead agencies would not have been able to accommodate you should we have had this request, as many office buildings were closed and personnel were directed to work from home. All comments mailed with the post-marked dates prior and up to April 13, 2020, or delivered by a delivery service with access to the mail room by 5:00 pm on April 13, 2020, were accepted. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. The 2-6% Smolt-to-Adult return ratio (SARs) target referenced in this comment refers to the Northwest Power and Conservation Councils (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia River Basin, the Councils recovery goals are shared by many parties. The spill operation for juvenile fish passage is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. Based on the fish analysis in Section 7.7.4 the Preferred Alternative will make a meaningful contribution towards recovery, but the Councils broad sense recovery goals are beyond the scope of this EIS which is limited to those effects associated with the operation and maintenance of the 14 CRS projects. With respect to the Preferred Alternative, the CSS model predicts that average SARs will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative increasing SARs from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse negative unintended consequences, such as long delays of adult migrants, or total dissolved gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
3970	2	Shelley Silbert	Great Old Broads for Wilderness	Recommendation Regarding the CRSO-DEIS Alternatives For reasons carefully detailed herein, CRSO-DEIS Alternative 3 (MO3) combined with 125% Total Dissolved Gas (TOG) spill at the lower Columbia River dams provides the soundest, science-based, boldest actions to bring Snake Basin salmon and steel head back to a 4% SARS level and to prevent their extinction. Breaching of the four lower Snake River dams must happen, and soon. Please read on.	The agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% total dissolved gas (TDG) at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For power and transmission, MO3 and Multiple Objective alternative 4 (MO4), individually each caused large loss-of-load probability (LOLP) results (e.g., increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these Multiple Objective alternatives (MOs) were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative. The agencies disagree that a combination of MO3 and MO4 is reasonable, and thus was not proposed as an alternative given the unacceptable risks to public safety from such an alternative.

					The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4 for the Preferred Alternative, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call however is ultimately the role of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply while minimizing adverse effects to communities and the economy. MO3 by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system.
3970	3	Shelley Silbert	Great Old Broads for Wilderness	Fish and Aquatic Resources The Columbia-Snake River Watershed was once one of the top salmon producing ecosystems in the world. Nearly 50% of the Columbia River's legendary runs of wild salmon and steelhead historically came from the Snake River and its tributaries. In 2017 only 250 pairs of wild Middle Fork Salmon River Chinook returned to over 600 miles of Idaho habitat, some of the best in the lower 48 states. The 2019 returns of adult fish were near record lows for steelhead, sockeye and Chinook salmon. These important stocks are at immediate risk of extinction. From the 1930s to the mid-1970s, the U.S. Army Corps of Engineers (USACE) built 14 dams throughout the Columbia Basin and its tributaries, along with several private entities that also built large dams. The primary purpose was hydroelectric power, with other purposes for transportation of goods such as wood products and grains, and water for irrigation on adjacent lands. Unfortunately, the dams and associated reservoirs created in the Columbia Basin and particularly the four Lower Snake River dams have led to a long downward spiral in anadromous salmon and steelhead, and many are near the brink of extinction1 . With steadily declining runs, Snake River salmon and steelhead runs were listed as threatened or endangered under the Endangered Species Act (ESA) by the early 1990s2 For the past 30 years, numerous mechanistic fixes have been tried including fish hatcheries, barging, predator control, endless fish-passage "improvements", and many more. The CRSO-DEIS basically proposes more of the same mechanistic fixes. With a changing climate and warmer and drier future, the proposed CRSO DEIS and selected "Preferred Alternative" will most likely lead to extinction of our region's iconic anadromous fish species	While the co-lead agencies do not dispute that dams have had impacts to the anadromous fish populations of the Columbia and Snake Rivers, the co-lead agencies also recognize that there are many effects to these species outside the impacts of CRS dams. Harvest, reduced habitat, poor ocean conditions, and others have significant impacts to these species. Extensive changes to structures and operations have improved survival of anadromous fish. Recent downturns in ocean conditions are a major contributor to recent decreases in return numbers. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The CSS model, which includes latent mortality effects, predicts that median Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, increasing SARs from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse negative unintended consequences, such as long delays of adult migrants, or total dissolved gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
3970	4	Shelley Silbert	Great Old Broads for Wilderness	1. The Snake River Dams Cumulatively Impact Anadromous Fish Populations A. General Cumulative Im2_acts and Historic and Current Abundance of Anadromous Fish The Columbia and Snake River Dams impact rivers, streams and aquatic habitats by altering natural flows, water quality and nutrients; trapping sediments, gravel, and woody material; and impeding and delaying fish passage and migrations. This was acknowledged in the CRSO-DEIS with the comment "In general, large dams have an influence on the riverine ecosystem downstream of the structure. Dams alter flow regime, temperature, oxygen dynamics, sediment dynamics, and channel geomorphology (shape and function)" (CRSO-DEIS, p. 3-232). In addition, the four lower Snake River dams inundated 140 miles of the lower Snake River, much of which was fall Chinook spawning habitat. Including the slackwater above Lower Granite Dam, fish are limited to the lower 247 miles of the Snake River up to Hells Canyon Dam, the lowest of three privately owned hydropower dams with no fish passage. Dams also cause high temperatures in the pools behind dams, increase predation, inundate spawning and rearing habitat, and increase mortality from stress and disease. The Columbia and Snake Rivers were changed from free-flowing rivers to a series of dams, with slow moving reservoirs that delay downstream migrating juveniles. Pools behind the dams become too hot for migrating salmon and steelhead, and have abundant predators such as northern pikeminnow and smallmouth bass. Fish from the Snake River must traverse eight large dams both upstream and downstream during their migration. With the completion of the four lower Snake River dams in the mid-1970s, anadromous fish have declined precipitously and are near extinction. For example, during years of low flows or excessive water withdrawal, smolts on the upper Snake River can now take up to 39 days to reach the ocean, compared with less than three days in the pre-dam environment 3 The Snake River, where anadromous species once measured in the hundreds of thousands or millions, is now home to remnant populations of four ESA-listed species of anadromous fish: spring/summer Chinook, fall Chinook, sockeye and steelhead. The following table summarizes how few fish are left of each of the four ESA-listed species of anadromous fish compared to historic abundance (Table 1)4 [included in document: Table of Lower Snake River ESA-listed Salmonids Historic and Projected Current Abundances] Other ocean-going fish include coho salmon and Pacific lamprey. Coho were extirpated from the Snake River in the mid-1980s with only a reintroduced population from a fish hatchery fish program remaining. Pacific lamprey also exist at extreme low abundance, with their status as critically imperiled, possibly extinct, and presumed extinct in different reaches of the Snake River and its main tributaries above the four lower Snake River dams, with trends in abundance severely declining5. Like salmon, Pacific lamprey are severely impacted by the lower Snake River Dams. Adult passage at these dams ranged from 41%-65%6 Downstream migrating juveniles and larvae, too are very susceptible to entrainment and impingement by hydropower dams. Returning wild fish estimates have been masked, especially recently, by the increasing number of returning hatchery produced fish. Hatchery fish were intended as a temporary mitigation measure for producing harvestable fish due to anticipated losses from the construction of the dams and reservoirs. The native wild runs remain at dangerously low levels, and continue to decline.	While the co-lead agencies do not dispute that dams have had impacts to the anadromous fish populations of the Columbia and Snake Rivers, the co-lead agencies also recognize that there are many effects to these species outside the impacts of CRS dams. Harvest, reduced habitat, poor ocean conditions, and others have significant impacts to these species. Extensive changes to structures and operations have improved survival of anadromous fish. Research continues to evaluate the magnitude of these effects. For more information see the National Marine Fisheries Service (NMFS) website at: https://www.nwfsc.noaa.gov/research/index.cfm. The assertion that salmon and steelhead declined precipitously after 1970 is in error. Point-in-Time (PIT) data show that total returns of salmon to Bonneville Dam in the last decade were more than double the 1970s values. Effects to anadromous species have been greatly mitigated by transportation and spill that have increased survival and greatly reduced travel times. In regards to comments regarding turbine passage, the statement that juveniles are very susceptible to impingement is also in error. The numbers of fish now passing turbines is very low and those that do have high survival rates. The recent design and installation of improved fish passage turbines at Ice Harbor Dam is just one example of the improvements being made for juvenile salmon. This turbine will pass fish at a survival rate of over 98 percent allowing for both high salmon survival and power generation.
3970	5	Shelley Silbert	Great Old Broads for Wilderness	B. Fish Passage Anadromous adult and juvenile fish passage over the eight dams to and from the Snake River are both problematic, with cumulative impacts on fish survival. The CRSO-DEIS acknowledges that adult fish experience cumulative mortality in their return to the Snake River: "The 10-year average {2008 to 2017} minimum survival estimate for hatchery and natural origin adult Snake River spring/summer-run Chinook salmon from Bonneville to McNary Dam is 89%, with a range of 83 - 100%, and from Bonneville to Lower Granite Dam is 84%, with range of 77 - 94% {NMFS 2019}. These survival estimates account for total losses from the dams and reservoirs, as well as any losses in these reaches that result from flow effects, temperature, disease, or other natural causes (NMFS 2019)" {CRSO-DEIS p. 3-383-384}. Another issue is that fish ladders are fragile systems prone to disruption; these disruptions will increase as the dam infrastructure continues to age8 Two of the four lower Snake River dams have only one fish ladder. If the ladder is not functional due to mechanical or other difficulties it significantly impacts or even prevents fish migration. Downstream migrating juvenile losses are generally higher than upstream migrating adults. The following is a summary of impacts as juvenile fish pass through each dam: "Physical injury, including brain damage, resulting from impacts with spillway structures and turbines, as well as hydraulic forces associated with spill and sudden depth changes are some of the main hazards associated with hydropower-related passage. Studies of the effect of exposure to severe hydraulic events on juvenile salmon have found a variety of adverse effects caused by strike, shear, pressure gradients, and disorientation. Recent studies have found that fish exposed to high shear and turbulence are subject to direct injury and are more susceptible to bird and fish predation than migrating salmon that have non-turbulent passage. Some of these detrimental effects are realized as delayed mortality, mortality that occurs after fish pass Bonneville Dam as juveniles that would not occur if the federal hydro system did not exist" The USACE asserts that downstream migrating spring/summer Chinook smelts survived at a per-dam rate of approximately 95%. In fact, Figures ES-4 {CRSO Executive Summary p. 19} and Figure 3-113 {p. 3-302} both assert very high rates of passage of juveniles through each of the lower Snake River and Columbia mainstem dams. However, these figures specifically refer to "performance standard" testing at projects in 2010-2014. They also fail to account for losses in the dams' reservoirs. For example, "Widener et al. {2018} estimated that juvenile Snake River spring-run/summer Chinook salmon survival rates {wild and hatchery combined) from Lower Granite to Bonneville Dam averaged 53% (ranging from 44 - 64%} for the same time period. These survival rates incorporate multiple sources of mortality such as passage mortality, natural mortality, and predation {NMFS 2019)" (CRSO-DEIS, p. 3-383}. Further losses are due to "delayed mortality" or "ocean latent mortality" which result from stress and harm that juvenile fish suffer as they pass through the eight dam and reservoir complexes. These losses further diminish juvenile fish survival in the estuary and after reaching the Pacific Ocean. Similar losses of cumulative survival through all eight dams, ranging from approximately 42% - 57%, are also noted for Snake River steelhead (CRSO-DEIS, p. 3-384}. Delayed latent mortality further diminishes survival in the estuary and the ocean. A better measure of survival to evaluate the entire life cycle of anadromous salmon and steelhead are "smelt to adult ratios" or "SARs." SARs are the gold standard for measuring survival since these ratios measure survival from the out-bound smelt stage to the returning adult stage. SARs encompasses most of the salmon life cycle. A SAR of 2% - 6% is needed to assure the survival of a fish species, but Snake River fish typically have SARs less than 2%, hence the continued downward spiral 10 Anadromous fish that pass through fewer hydroelectric dams on the Columbia River system have higher SARS and higher levels of survival (Figures 1 and 2}. [included in document a bar graph: Comparative Smolt to Adult Return Rat es (SAR s) for "Dow nriver" and "Upriver Wild St eelhead and Salmon] Figure 1. Comparison of Smalt to Adult Return Rates (SARs) for wild Chinook and Steelhead for the Deschutes, John Day, Yakima and Snake Rivers. Note more dams equates to lower survival	It should be noted that the 2-6% SAR target referenced in this comment refers to the Northwest Power and Conservation Council (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or, in this case, is not a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both federal and non-federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the analysis of the Preferred Alternative, it will make a substantial contribution to recovery, but the Councils broad sense recovery goals are beyond the scope of this EIS which focuses on the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. That call, however, is ultimately the role of NMFS and the USFWS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The co-lead agencies used current high quality information in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (within the Council's recovery targets for the region) as a result of the Preferred Alternative. The NMFS COMPASS and Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. In relation to the comment that fish passing few dams have higher SARs and survival, the co-lead agencies follow the guidance from the Independent Science Advisory Board, to not typically weigh performance of one population vs. another. It is difficult to isolate causative factors in those types of comparisons.

				and SARs 11 . [included in document a map of Yakima, Deschutes, John Day and Snake River] Figure 2. Comparative Survival Studies for Adult Returns of Anadromous Fish to the Deschutes, John, Day, Yakima and Lower Granite Dam on the Snake River. The listed species of salmonids that inhabit the Columbia/Snake River system are a very long way from meeting regional recovery goals that the Northwest Power and Conservation Council (NPCC} have stated. The NPCC asserted that "The program continues to include a set of quantitative goals and related timelines for anadromous fish. These include, among others, increasing total adult salmon and steelhead runs to an average of 5 million annually by 2025 in a manner that emphasizes the populations that originate above Bonneville Dam and supports tribal and non-tribal harvest, and achieves smolt-to-adult return rates in the 2% - 6% range (minimum 2%; average 4%) for listed Snake River and upper Columbia salmon and steelhead." It is apparent from present salmon returns that 50% juvenile survival of Snake River salmon to below Bonneville Dam is insufficient to meet regional 2% - 6% SAR goals. Like Snake River coho, Chinook, sockeye and steelhead are doomed to extinction unless strong measures of a combination of dam breaching of the four lower Snake River dams, and the highest spill levels of 125% TDG at the remaining dams on the lower Columbia mainstem river, are implemented.	
3970	6	Shelley Silbert	Great Old Broads for Wilderness	C. Water Quality High water temperatures caused by Snake River and Columbia mainstem dams and reservoirs that have stagnant water flows, as well as discharges and climate change, are deadly to migrating fish like salmon. Anything above 68F/20C makes it extremely difficult for fish to migrate upstream to spawn. High temperatures affect adult salmon migration by direct mortality, migration delay, and may deplete energy through delay and increased respiration, reduced gamete viability, and increased rates of disease14 . The Fish Passage Center analyzed how temperatures in the Bonneville forebay cause long travel times for upriver steelhead as water temperatures increase. They observed that both Snake River and Upper Columbia steelhead rarely had travel times of greater than 50 days until Bonneville temperatures reached 19- 20C/ 66.2-68C15 . In the hotter and drier than normal summer of 2015, approximately 96% of returning Snake River sockeye salmon run died prematurely in the Columbia and Lower Snake rivers (approximately 250,00 fi sh). The reservoirs, together with record high air temperature and low flows, caused the water to become excessively warm. Most Snake River sockeye failed to reach the Snake River in 2015 having died in the Columbia River. As noted above, Snake River sockeye are an ESA-listed endangered species. The year 2015 is a harbinger for future effects of climate change impacts to water temperature and flow conditions. Events similar to those in 2015 are likely to become more frequent as climate change intensifies. Schultz and Johnson {2017) used a water temperature model to demonstrate that a free flowing Lower Snake River would have remained cooler than 68F/20c during most of the summer of 201516 . By comparison, water temperatures in reaches of the lower Snake River that are dammed, most particularly the three downstream reservoirs, reached 68F/20c in mid to late June and remained near or above 68F/20C until September. The Snake River at Ice Harbor Dam reached 70F/21C by the beginning of July and stayed at least that warm until late August {Figure 3). [included in document graphs: 2015 Actual River Temperatures and 2015 Free-flowing River Temperatures (predicted)] Figure 3. Comparison of 2015 summer water temperatures between the actual, dammed Lower Snake River {left) and a modeled, free-flowing Lower Snake River {right). Figure 3 shows the cumulative effect on temperature as the water moves slowly downstream through the four Lower Snake reservoirs, with each reservoir increasing the river temperature by about 2F/1.1C. Rising temperatures were absent from a simulated free-flowing Snake River. Without the dams, water temperatures in the lower Snake River would warm a relatively minor amount as it flowed across eastern Washington. The results by Schultz and Johnson {2017) validate the Environmental Protection Agency's {EPA) previous finding that each Lower Snake River reservoir can raise the water temperature by roughly 2-4F/ 1.1-2.2C17 . Schultz and Johnson also demonstrated that "pulses" of hot water move past each dam over time, caused by hot weather or low flows upstream. The simulation showed that a pulse of hot water took approximately two weeks to pass through the dammed lower Snake River, while in the absence of the dams that same hot pulse would pass through the free-flowing river in a few days. The simulation model clearly established that despite the dangerously hot air temperatures and low flows that occurred in 2015, the Lower Snake would have remained sufficiently cool for salmon to migrate in the absence of the four lower Snake River dams. Essentially, a free-flowing lower Snake River could remain sustainable salmon habitat from a water temperature perspective, despite climate change. Their results demonstrated that a free-flowing lower Snake River would have temporarily exceeded 68F/20C on two occasions in 2015. The simulation modeling also indicated that a free-flowing lower Snake would have returned to temperatures that salmon can migrate in within a few days. The dammed lower Snake downstream of Lower Monumental Dam consistently exceeded 68F/20C from late June to early September, and caused sustained, cumulative exposure to water above 68F/20C that resulted in the adult salmon mortality observed in 2015. Warm water harms salmon not just in the lower Snake River, but throughout the entire river system from the Snake River tributaries in central Idaho to the Columbia River estuary. Most of the 2015 Snake River sockeye run died from warm water before reaching the lower Snake River. Of the few that passed Lower Granite Dam in 2015, a very small number survived the rest of their migration to Idaho's headwater streams in the Sawtooth Valley. Problems with temperatures and low flows in the Columbia and Snake rivers will intensify as the effects of climate change increase . The only options to ensure survival and avoid extinction of Snake River anadromous fish is to have a free-flowing lower Snake River. Excessively high water temperatures, above 20C/68F, are now normal for extended periods in July, August, and Sept ember 18 . EPA {2003} reported that a free-flowing lower Snake River would, on average, be 3.5C/6.3F cooler in late summer and early fall when measured at the site-potential for John Day Dam. EPA modeling also demonstrated that the combined four lower Snake Dams could affect temperatures up to a potential maximum of 6.8C/12.2F. Without breaching these dams, water temperatures will remain lethal for migrating salmon and will worsen as the climate continues to warm. The report by Cannemela (2019} representing 55 scientists concluded that "restoring the lower Snake River by removing its four federal dams will significantly reduce mainstem water temperatures on a long-term basis, and is likely the only action that can do so, substantially lowering the risk of extinction for salmon and steelhead here."	The Draft EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives effects on Snake River stocks, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Regarding climate change, the climate science community is still developing models at the resolution necessary (river-scale vs. global- or regional-scale) to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at this time. Therefore it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3). Regarding water temperatures under dam breach scenarios, the analysis of MO3, which includes breaching the four lower Snake River dams, indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action Alternative conditions in the Snake River. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events. The models showed minor changes in the Columbia River under this alternative. Regarding the whitepaper published by the Columbia River Keeper, Schultz and Johnson (2017) use an old version of RBM10 (2003) to evaluate temperatures in 2015. The EIS analysis included an evaluation of the Environmental Protection Agency's (EPA's) more recent RBM10 model (draft 2019), specifically comparing 2015 Snake River conditions. EPA's temperature predictions using the updated RBM10 model did not contradict the EIS evaluation.
3970	7	Shelley Silbert	Great Old Broads for Wilderness	2. The CRSO-DEIS Proposes Continuation of the Status Quo A. The Preferred Alternative is Worse Than the Status Quo From an operational standpoint, the Preferred Alternative is essentially the same as the 2020 Flex Spill Agreement 20 . The Flex Spill operation involves hourly changes in spill, where higher spill levels are provided for 16 hours and lower "performance spill" levels are provided for 8 hours. Both higher and lower spill levels are provided during daytime and night time hours. When considering the Comparative Survival Study {CSS) analyses of the Preferred Alternative done by the Fish Passage Center, and specifically estimates of powerhouse passage by juvenile fish, the estimates are likely an underestimate of fish passage through the powerhouse. The CSS analyses of CRSO-EIS alternatives are based on the 80-year water record datasets generated by the federal agencies. The datasets present the Preferred Alternative in terms of daily average flow and spill, although the Preferred Alternative is implemented on an hourly, not daily average time st ep. Therefore, the estimates of juvenile powerhouse passage generated on the basis of the federal dataset does not reflect the higher powerhouse encounters that occur from implementing lower performance standard spill during evening and night time hours. The Fish Passage Center reported that the Preferred Alternative did not meet the regional 4% SAR goal, and the lower end of the predicted SAR ranges were well below 1% which indicate a high risk of further population decli ne. For all fish survival metrics, the Preferred Alternative resulted in only slightly better performance than the No Action Alternative and the MOI Alternative, and had lower performance than both MO3 (dam breach) and MO4 (spill to 125% TDG). The discussion of the Preferred Alternative and other operation alternatives does not include any specific numerical identification of benefit to ESA-listed salmon and steelhead {CRSO-DEIS Executive Summary, p.32). The goal is only generally described as "improving juvenile salmon and improving adult salmon." The Northwest Power and Conservation Council {NWPCC) established regional SAR goals of 4% (on average) for recovery of listed populations, but none of the DEIS's alternatives achieve that goal except for MO3 (dam removal).	Actual spill operations will be informed by guidelines informed by regional state, tribal, and Federal experts as part of ongoing flexible spill management. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. All models were reviewed in the Independent External Peer Review process. All models produce estimates and are not exact. In practice, model estimates may overestimate due to day vs night passage differences because limitations on nighttime spill reductions are already in place through the adaptive management process and lessons learned from the 2019 flexible spill operation. These adjustments in the amount of nighttime spill were informed by state, tribal, and Federal biologists with expertise in dam operations and their effects to fish passage. These examples of adaptive management will continue during post-Record of Decision (ROD) operations. The 4% average Smolt-to-Adult return rates (SARs) target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the fish analysis in Section 7.7.4, the Preferred Alternative would make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The CSS model predicts that average SARs would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative increasing SARs from 2.0% to 2.7% for Chinook, a 35% relative increase. While some outcomes in individual water years or river conditions may be lower than desired, the average trend is expected to be positive and lead to increasing populations over time. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse negative unintended consequences, such as long delays of adult migrants, or total dissolved gas (TDG)-related mortality of juvenile migrants. The Executive Summary is a high-level summary of the analysis contained in the rest of the Draft EIS. It does not contain as much detail as the Draft EIS. Please see Section 3.5, Chapter 7, and Appendix E for more detail on the analysis.
3970	8	Shelley Silbert	Great Old Broads for Wilderness	B. The Preferred Alternative is completely inadequate, and fails to make significant improvements for Snake River salmon and steelhead populations The Preferred Alternative is worse than adherence and continuation of the status quo because it only mandates flex spill for one year, the last year of the Flex Spill Agreement (CRSO-DEIS p. 7-15, Section 7.4 Summary). After the completion of the spill agreement there is only a "process". The Flex Spill Agreement was intended to avoid litigation during the time frame that the CRSO DEIS was being developed. The Preferred Alternative is the current short-term flex spill agreement with modifications that benefit power production revenue and irrigation. There are no improvements for Snake River salmon and steelhead populations included in this alternative. The Preferred Alternative does not include operations for the long term, and only addresses operations for the last year of the Flex Spill Agreement (2021). For future years the Preferred Alternative makes references to an undefined adaptive management process that has no defined objective that could meet the regional 4% average SAR goal, increase spill for fish passage, increase flow for migration, or implement hydro system actions that would increase life cycle survival. The Preferred Alternative includes measures that will continue to harm salmon and steelhead populations, such as additional irrigation water withdrawals from the Columbia River that total 1.254 million acre-feet. The Preferred Alternative is clearly just a continuation of the status quo. The Preferred Alternative claims to include a "balanced approach," but continuation of the current strategy is what has brought Snake River salmon and steelhead to their present perilous st at us. There are no assurances in this undefined adaptive management process that conditions for Columbia and Snake River salmon and steelhead populations would improve. The CRSO DEIS proposes to continue with more mechanistic fixes for salmon and steelhead that have failed to work in the past, thereby most likely assuring	The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. The framework for the adaptive management process is detailed in Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS. It is the intention of the co-lead agencies to engage regional state, tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams such as the Technical Management Team. The co-lead agencies disagree that the short-term nature of this operation is an accurate interpretation of the Preferred Alternative. If no adaptive management needs are identified, the operation would continue through the duration of the ESA consultation period. The co-lead agencies have provided additional clarifying text in Appendix R to make these points more clearly. Relating to the claim that the Draft EIS relies on more mechanistic fixes because the co-lead agencies have constructed numerous structural changes to improve salmon and steelhead passage (e.g. spillway weirs) over the past decades, there are few additional mechanistic fixes proposed in the Preferred Alternative. Most of the structural improvements are focused on improvements for lamprey passage. Other changes, such as turbine replacements are not expected to have beneficial impacts to salmon and steelhead survival that are of a magnitude that would outweigh the modeled effects associated with the higher spill levels in the Preferred Alternative. The Preferred Alternative does not contain any proposed decreases to river flow levels that are expected to impact juvenile salmon migrating during spring and summer. Any changes in flow would be small enough to have minor to negligible impacts or occur outside of the juvenile migration season and are limited to areas of the basin where the impact would be negligible or minor.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the extinction of salmon and steelhead in the Snake River. The Preferred Alternative proposes to continue to implement the Flex Spill Agreement, but includes measures that are not included in the Flex Spill Agreement such as the decrease of spring and summer flows that would clearly impact spring and summer migrants. In addition, the language of the Flex Spill Agreement clearly states the purpose of the agreement was to avoid litigation for three years while the CRSO-DEIS was being developed. The Flex Spill Agreement states that "no Party makes any concessions regarding the legal validity, scientific validity, or economic cost/benefit of the spill operations contemplated in this Agreement ." A review of the Flex Spill in 2019 demonstrated that downstream survival, juvenile fish powerhouse encounters, and water transit time of juvenile fish was no better and sometimes even worse than the status quo of the 2018 Biological Opinion (BiOP) spill flows. For example, Figures 4 and 521 demonstrate that the "new and improved" flex spill for 2019 (orange bars) would result in lower survival compared to the 2018 BiOP flows (blue bars). [bar graph included in document] Figure 4. Comparison of 2019 juvenile survival from Lower Granite Dam to Bonneville for steelhead cohorts to the average survival for the same cohorts in the years 1998 to 2018. [bar graph included in document] Figure 5. Estimated reach survivals of juvenile steelhead in 2019 versus model predicted survivals, based on powerhouse encounters and water transit time that each cohort experienced in 2019. The 2019 Flex Spill was intended to improve juvenile survival of downstream migrating fish. The agreement states that fish passage must be better or at least no worse than what would have occurred under the 2018 court ordered injunctive spill order. In 2019 fish passage through powerhouses was worse than the injunctive spill order. More fish went through powerhouses than would have occurred under the injunctive spill order. Flex spill is a multi-year experiment intended to providing higher spill in 2020 and 2021, but results of this experiment will remain unknown until after the 2020 and 2021 spring spill efforts. There are serious flaws and adverse components of the Flex Spill Agreement. Spill to the higher 125% gas cap level is only provided at four of the eight Columbia and Snake hydroelectric projects. At Bonneville, The Dalles, and John Day dams, spill is capped at 120% TOG, and these projects are allowed to reduce spill for 1/3 of the 24-hour cycle day which decreases fish protection at these projects. It is therefore unlikely that the Columbia/Snake hydropower system will meet the stated purpose of the agreement. Because spill is reduced at the lower river projects, Oregon and Washington stocks from the John Day, Deschutes and Yakima Rivers are likely to have increased powerhouse encounters and decreased survival. Given the obvious weaknesses of the Flex Spill Agreement, from the fish recovery prospective it does not provide a path forward to recovery. The Fish Passage Center sent a memo to the federal action agencies on January 24, 2020, that clearly demonstrated that the Preferred Alternative is a high risk alternative for Snake River salmon and st eelhead. 22 In the lower quartile data range, low SARs and continued population decline (1% SAR} are predicted to occur a significant portion of the time. This is even more likely to occur with changing climate change conditions. The Preferred Alternative is inadequate because it makes no substantive changes to restore Snake River salmon and steelhead. There are only vague references to "adaptive management processes" which are a continuation of the failed history to restore Snake River anadromous fish. Frankly, Snake River Salmon and steelhead populations are out of time. The Proposed Alternative carries significant risk for ESA-listed salmon and steelhead (particularly in light of climate change}, not only that they will not recover but that they will go extinct. Scientific analyses in the CRSO-EIS leads to the conclusion that breach of the four lower Snake River Dams is the only option that has potential for recovery of Snake River salmon and steelhead. Based upon the data and analyses used to develop the CRSO-DEIS, the Great Old Broads for Wilderness recommend that the Final EIS establish the objective to balance hydropower generation with substantive and meaningful restoration of anadromous fi sh. This is clearly not the objective of the Preferred Alternative, which places greater emphasis on power production while anadromous fish survival is relegated to "tweaks" of the existing hydro system. Meaningful restoration of salmon and steelhead must include breaching the four lower Snake River dams (MO3 alternative), with plans and a schedule to accomplish that goal. In the meantime, until the dams are breached, the analyses of alternatives clearly demonstrate that spill to the 125% tailrace gas cap (MO4 alternative} at all of the projects, 24 hours per day, must be implemented as an interim measure. Analyses in the CRSO-DEIS show this is the best available option for salmon and steelhead recovery, while still providing sufficient regional energy.	After careful review of monitoring data from the 2019 flex spill operation, the flex spill signatory entities agreed that all biological, hydropower generation, and operational aspects of 2019 met all parties expectations. It is difficult, and not advisable to take a single year of data from an operation, such as the single year of 2019, and make long-term and long-range decisions based on a limited operation. That is why the parties to the agreement based their expected outcomes on multiple water conditions and potential outcomes. When considering benefits to fish, the flex spill parties used powerhouse encounter rate or PITPH as the primary metric, not in-river survival, or even Smolt-to-Adult return ratios (SARs) due to the variation in those metrics and the limited opportunity to evaluate and monitor based on a single year of data. See also response to comment 3970-10 regarding sufficiency of regional power supply. Lastly, the commenter incorrectly states that the Preferred Alternative diverts an additional 1.254 MAF for irrigation. The Preferred Alternative diverts an additional 45 KAF for irrigation, a substantially lower value than what was evaluated in Multiple Objective alternative 1 (MO1), MO3, and Multiple Objective alternative 4 (MO4).
3970	9	Shelley Silbert	Great Old Broads for Wilderness	C. The CRSO-DEIS Incorrectly Claims that it is a Collaborative, Adaptive Management Process and Continuation of the Flexible S.P.ill...agreement One of the more egregious statements in the CRSO-DEIS, and the clearest evidence of the primary failure of the CRSO-DEIS, is the claim of a collaborative, adaptive management process. The CRSO-DEIS stated that "the co-lead agencies are creating an additional opportunity to test the assumptions about the potential for significantly increased salmon survival embedded in the CSS model through the adaptive implementation of a flexible spill operation" (CRSO-DEIS Executive Summary p. 13). This is clearly a continuation of the status quo, a status quo that has been continued for over 30 years at the expense of salmon and steelhead populations of the Snake River Basin. Collaboration and adaptive management will fundamentally perpetuate the status quo at the expense of salmon and steelhead runs which are on the brink of extinction. Snake River salmon and steelhead have been ESA-listed species for the past 30 years. Unfortunately, ESA listings have not resulted in the actions necessary to recover these iconic salmon populations. The path forward outlined in the CRSO-DEIS is a path that the Pacific Northwest has followed before. The long history of good intentions, collaboration, and broken promises was clearly documented in "Sacrificing the Sal mon."23 Blumm (2013) stated that "The promises to these salmon populations and the industries and people that depend on them, of the Northwest Power Act, The Endangered Species Act, the Clean Water Act to name just a few, have all been broken." Broken promises include a century of hatchery operations which aimed to compensate for habitat loss due to hydroelectric and other development s. These promises, as well as those made by the Northwest Power Act, the Pacific Salmon Treaty, the Endangered Species Act, the Clean Water Act, and the Federal Power Act have demonstrated that the co lead agencies are unable to reverse the decline of Snake River Basin salmon and steelhead. Instead, collaborative processes and adaptive management have been offered in place of action. The CRSO-DEIS is repeating a failed history, and proposes promises that have already been broken. It is obvious that the Federal hydro system has been developed beyond the point of balance with salmon and steelhead, and that some of the development needs to be undone. The objective of this CRSO-DEIS appears to be to continue to maintain the status quo hydro system development and configuration. The region has pursued the goal of maintaining the status quo hydro system operation over the past 40 years, investing in considerable effort and funding in fish hatcheries, habitat projects, killing predators, barging juvenile fish, building endless screen systems, bypass systems, forebay contraptions, and forebay nets, attempting everything and anything to "restore" salmon and steelhead. The history is well documented and the approach has not been successful and will not be successful in the future.	Regarding the Preferred Alternative, this alternative is not simply a minor change to operations and maintenance of the CRS. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The CSS model, which includes latent mortality effects, predicts that median Smolt-to-Adult return rates (SARs) will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative, increasing SARs from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse negative unintended consequences, such as long delays of adult migrants, or total dissolved gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The levels of spill proposed in the Preferred Alternative have never been implemented on a season-wide basis before and were previously outside of allowable limits in place for water quality purposes. This new level of operation must be carefully and thoroughly tested to assess actual results compared to model based expectations. Because of the uncertainty between the outputs of the two models for salmon and steelhead, the co-lead agencies have proposed a robust monitoring program that will be developed with Federal, state, and tribal experts in salmon biology and monitoring.
3970	10	Shelley Silbert	Great Old Broads for Wilderness	3. The Dam Breach Alternative (M03) Combined with 125% TDG Spill (M04) is the Best and Only Chance to Restore Anadromous Fish In response to requests from the federal agencies, the CSS Oversight Committee applied CSS life cycle and cohort models to evaluate federal CRSO-DEIS operation alternatives (Fish Passage Center, 2020a). The six operational alternatives analyzed included the No Action Alternative, Multi-Objective Alternatives 1-4 (MO1, MO2, MO3, and MO4), and the Preferred Alternative. It did not include a SAR-focused alternative to restore Snake River salmon and steelhead. The Fish Passage Center used the 2017 CSS scenario of breach of the lower Snake River Dams, and spill to the 125% tailrace TDG levels in the Middle Columbia River, as a SAR focused "bookend." To provide this SAR focused "bookend" in the context of the CRSO-DEIS scenarios, the CSS added a seventh alternative (MO34) to these analyses using the 80-year water record. The non federal MO34 alternative demonstrated the greatest expected improvements across all biological response metrics, compared to all of the other federal CRSO-DEIS alternatives, and exceeded the 4% average SAR regional goal (Fish Passage Center 2002a). Even the lower end of the predicted SAR range for MO34 was above 1% for both Snake River Chinook and steelhead, indicating that further population decline could be avoided. Among the federal alternatives, MO3 (the four dam breach alternative with spill to the 120% tailrace TDG in the Middle Columbia River) resulted in the highest SARs and in-river survivals, followed by MO4 (the spill to the 125% tailrace TDG alternative). These two alternatives, among the federal alternatives, resulted in the highest likelihood of meeting the 4% average SAR regional goal. The lower end of the predicted SAR range for MO3 was also above 1% for both Chinook and steelhead. However, for MO4 the lower end of the predicted SAR was slightly below 1% indicating a greater risk of further population decline. The other federal alternatives (No Action, MO1, MO2, and the Preferred Alternative) all failed to meet the regional 4% SAR goal, and the lower end of the predicted SAR ranges were well below 1%, indicating greater risk of further population declines under each of these alternatives. For all fish survival metrics, the Preferred Alternative resulted in only slightly better performance than the No Action and MO1 alternatives, and had lower performance than both MO3 and MO4 alternatives. The Fish Passage Center also noted that the "scenario of 125% TDG spill level at the Lower Columbia projects (McNary to Bonneville) and breach of the Lower Snake River projects was analyzed in the 2017 CSS Annual Report 24 and was found to have the highest benefits in terms of fish performance metrics. However, this promising scenario was not included in the CRSO-DEIS alt ernat ives 25. Several statements in the CRSO-DEIS acknowledge that improved conditions for salmon and steelhead survival could occur with removal of the four lower Snake River Dams. The CRSO- DEIS states that for MO3 (dam removal) "On the lower Snake River, changes to flow amounts would be minor since the four lower Snake River Dams are run-of-river projects, not storage projects. However, without the reservoirs, the water particle travel time through the reach could be reduced by an order of magnitude" (CRSO-DEIS, Table 3-1, p. 3-5). The CRSO-DEIS further acknowledged that "effects to Snake River anadromous species are expected to be a major beneficial effect after short-term major adverse effects associated with dam removal stabilize. Minor beneficial effects for lamprey are expected" (CRSO-DEIS Table 3-1, p. 3-7). The	The co-lead agencies contracted with the Fish Passage Center (FPC) to produce the CSS modeling results presented in the Draft EIS. Any additional modeling that was not presented in the Draft EIS is not part of the CRSO EIS and was not developed or reviewed by the co-lead and cooperating agencies as part of this EIS. The co-lead agencies are unsure what information or assumptions CSS used in their separate modeling effort and note there is not a corresponding alternative modeled under the National Marine Fisheries Service (NMFS) Lifecycle model. The agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% total dissolved gas (TDG) at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. MO3 and Multiple Objective alternative 4 (MO4), individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these Multiple Objective alternatives (MOs) were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is approximately the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire United States by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching in the MO3 would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted, and built to address these impacts. These are in addition to the other adverse effects to the human and natural environment described in MO3 and MO4 individually. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative. The co-lead agencies acknowledge in the Draft EIS that implementation of MO3 would have benefits to salmon and steelhead. However, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives, including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				CRSO-DEIS stated that "Over the long term, MO3 would have moderate to major beneficial effects on water quality in Region C through the restoration of natural, river, and water quality processes; a substantial cooling effect in the fall; greater nighttime cooling and respite from warm water temperature conditions in the summer; and a reduction in overall system TDG" (CRSO-DEIS, p. 3-275). Meanwhile under the CRSO-DEIS with the four dams in place, "The cooling effect in the lower Snake River diminishes at each successive downstream reservoir and the frequency of exceedances above the [temperature] standard increases" CRSO-DEIS, p. 3- 238.	
3970	11	Shelley Silbert	Great Old Broads for Wilderness	For over twenty years federal judges have determined that five consecutive biological opinions for the Columbia-Snake hydropower system are illegal and inadequate in terms of protecting steelhead and salmon. Taxpayers and electricity ratepayers have spent at least $17 billion dollars on fish recovery yet these species continue to decline. Breaching the lower Snake River Dams, as indicated by analyses completed by the Fish Passage Center, could lead to a fourfold increase in Snake River salmon and steelhead numbers, which would allow wild salmon the opportunity to recover to sustainable levels26. The Fish Passage Center 2017 Annual Report assessed the potential survival benefits to Snake River spring/summer Chinook as a result of increased spill and dam breach in the lower Snake River. The most significant benefits to in-river survival rates and SARs occurred at the highest TOG limit spill levels (125% TDG), and under dam breached conditions. The authors' results indicate that SARs in the 4 - 6% range occur under most dam breached and spill levels, where the variable juvenile encounters at powerhouses dropped 1.5% and the variable water transit time for fish declined to the 8 - 15 day range. The authors noted that the breached scenario SARs are comparable to the historical SARs of John Day Chinook, which experience five less powerhouses than Snake River Chinook with no dams breached. Historical John Day SARs have been in the 2 - 8% range. Spill and breach scenarios provide a relatively immediate means of increasing life cycle survival, both during in-river migration, and upon ocean entry. If the lower four Snake River Dams are breached and the remaining four lower Columbia River Dams operate at BiOP spill levels, there will be an approximately a 2 -3 fold increase in abundance above that predicted at BiOP spill levels in an impounded system, and up to a 4 fold increase if spill is increased to the 125% TOG limit. Dams in the Columbia River hydro system have created slack-water reservoirs, and on the lower Snake River have inundated over 140 river miles of natural habitat. By 1997, all Snake River salmon and steelhead runs had been federally listed as threatened or endangered under the Endangered Species Act (ESA). In recent years, Chinook salmon and summer steelhead returning adults are so low that fisheries officials have mandated fishing closures in most areas of the Snake River basin and its tributaries. These fishing closures have caused terrible economic hardships to fishing-related rural communities, and businesses and angling recreationists. Breaching the four federal dams on the lower Snake River is the single major step needed to avert extinction of the lower Snake River salmon, and to restore access of salmon and steelhead to 15 million acres of cooler, high-elevation watershed. This would substantially increase access to spawning habitat for lower Snake River Chinook and summer steelhead, as well as assist migrating juvenile fish downstream to the ocean. Major rivers such as the Clearwater and Salmon (and their tributaries) are historic spawning habitat, with watersheds in near pristine conditions due to protected wilderness st at us. Chinook and steelhead swim as far as 900 miles to natal headwater streams, and climb some 7,000 vertical feet from the ocean to spawn in central Idaho. The clear cold waters will be increasingly important as the high elevation mountain snowpack in Idaho is more resistant to climate change, and the waters remain cold where other lower, more southerly rivers will likely become too warm and dry for salmonids. Restoring a free-flowing Snake River will enable protection and restoration of threatened or endangered wild salmon and steelhead facing extinction. Contrary to the statements made in the CRSO-DEIS regarding financial costs of each alternative, American taxpayers and Northwest energy consumers will not be severely impacted by dam removal, and 15,000 acres of prime riverine habitat and agricultural land can be recovered and reinvigorated. Recovery of Chinook salmon and steelhead populations will restore fishing opportunities for anglers and other recreationists and restore rural communities. The CRSO-DEIS claims that the document is "balanced", "collaborative", and "adaptive" are frankly untrue. The only substantive measures that restore salmon are the combination of breaching the four lower Snake River Dams, and running spill operations at the four mainstem Columbia dams at 125%. The CRSO-DEIS is once again putting power generation and ancillary benefits over restoration of fish. The document is not "balanced", "collaborative", or "adaptive" in any way. The idea of dam breaching and removal is not new or radical. In the past 100 years, over 1,700 dams have been removed around the United States, sometimes to restore fish passage, sometimes to remove a safety risk, and sometimes to avoid reconstructing costly infrastructure. A record 90 dams were breached in 2019 alone. Decades of removing old, obsolete dams has restored native fish runs that have been lost or suppressed for centuries. Recent examples include dam removals on the Hood River, White Salmon River and Elwha River in the Pacific Northwest. In each case, there have been astonishing signs of native fish species returning in abundant numbers. For example, after almost 100 years the Condit Dam on the White Salmon River in Washington was removed in the fall of 2011. Within two years, fish that had been extirpated from this river (Chinook, coho and steelhead), or at a very high risk of extinction (fall Chinook), had moved up above the dam and dramatically increased in abundance and distribution. Similarly, the Elwha and Glines Canyon Dams in Washington, built over 100 years ago, had 12 species of anadromous fish that immediately traveled above the dams upon removal, and increased in abundance and distribution. Dramatic increases in marine and wildlife species were also noted with the restoration of the Elwha River delta. The removal of the two dams on the Elwha River in 2012 and 2014 provided salmon access to an additional 71 miles of upstream habitat. Research showed that the fish migrated farther into the river and its tributaries following removal, with 58 Chinook nests identified above the dam removal sites in 2016, two years after dam removal.	The co-lead agencies used high quality information for the EIS analysis. The agencies did not rely on the Fish Passage Center (FPC) analysis used in the 2017 Annual Report, as the agencies contracted with the FPC to run the CSS model using both current hydrology simulations and each hypothetical operation and configuration represented in the alternatives. It is difficult to make direct comparisons between actions taken to breach other dams and the effects of breaching the four lower Snake River dams because of inherent differences in location, size, and purposes of the dams. For example, the effects of removal of the Elwha Dam and the effects of breaching the four lower Snake River dams are not comparable. Elwha Dam had a nameplate capacity of just under 15 megawatts. Its annual power production pales in comparison to the 1,100 aMW provided by the lower Snake River dams. Unlike the four Snake River projects, Elwha Dam did not have fish passage. Removal of the Elwha dam allowed the Elwha River to flow freely, whereas if the four lower Snake River dams were breached the Snake River would still have regulated flows due to the dams located upstream. Please also see the response to your comment 3970-10. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. Different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the National Marine Fisheries Service (NMFS) COMPASS model, juvenile Snake River Spring/Summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Lifecycle model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are similar (10% absolute improvement, or 23% relative juvenile survival increase; Smolt-to-Adult return rates (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River Spring/Summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2%). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SARs increase by 177% (from 1.8% to 5%). Though differing in predictions, both models predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One model simply predicts adult return increases an order of magnitude higher than the other. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. The Draft EIS acknowledges and describes the temperature sensitivities of salmon and steelhead, as well as the many other factors that affect these fish. Water quality and hydrology modeling data were inputs into the fish survival models used to analyze the alternatives effects on Snake River stocks, so temperature effects to survival have been incorporated into the overall analyses of each alternative. Regarding climate change, the climate science community is still developing models that can be used to analyze possible effects to water temperature from climate change, and unfortunately, there are not reliable models at this time at the appropriate resolution (river-scale vs. global- or regional-scale). Therefore, it was not possible to reliably model water temperature changes under climate change for this EIS. In lieu of this information, the climate analysis used the output from the water quality models under historical conditions, climate change data, and scientific literature to qualitatively assess potential effects to water temperature (Section 4.2.3). Regarding lower Snake River water temperatures, the EIS analysis indicates that nighttime summer water temperatures, as well as fall water temperatures, would be cooler than No Action conditions if the lower Snake River dams were breached. However, even with the dams breached, maximum summer water temperatures would exceed state water quality standards (20C) at times, especially during hot weather events.
3970	12	Shelley Silbert	Great Old Broads for Wilderness	4. Without Restoration of ESA- Listed Species the Co-Lead Agencies Increase the Risk of Extinction The ESA requires the federal government to recover these salmon species28 . For the Snake River in particular, both old and new research shows that dams are a major cause of decline of the salmon runs. Both fall and spring-run Chinook (which had collapsed to near extinction) were listed as threatened in 1992. Snake River steelhead were listed as threatened in 1997. Wild salmon are a part of nature's trust which governmental agencies have a special management obligation to protect under the long-standing public trust doctrine. Federal and State agencies have an obligation to maintain the wild salmon legacy in good health for citizen beneficiaries of present and future generations. The extensive listing of Pacific salmon stocks under the ESA is a strong signal that the current salmon management paradigm has failed. The USACE is required to review federal dam operations when advisable, and to improve the quality of the environment for the overall public interest (33 U.S.C. 549a). The Preferred Alternative does not meet the legal test because it fails to restore the viability of salmon and steelhead to the regional recovery goals. Fishery managers avoid responsibility for their failure in leadership and stewardship with the excuse that degradation and loss of productivity is the inevitable result of population growth and its attendant demands for development and economic growth. An obvious example are Snake River coho where only one fish was counted in 1985 and 1986 crossing Lower Granite Dam in the Snake River. In 1987 none returned. Federal actions designed to recover listed salmon and steelhead populations have been mired in trying to "balance" the Columbia hydro system. Meanwhile, no salmon or steelhead populations have recovered enough to warrant delisting, and instead are headed toward extinction like the coho salmon. The Snake River Basin is the major upstream salmon-producing tributary in the Columbia River Basi n. The importance of Snake River salmonid production cannot be overstated with respect to life history types and diversity. Declines of Snake River salmon occurred over decades, but population decreases accelerated starting in the 1960s and 1970s with construction of the four lower Snake River Dams. Estimated annual returns of spring/summer Chinook declined from 125,000 fish in 1950-1960 to just 12,000 fish by 1979. By 1994, Chinook run size was estimated at less than 2,000 adults. Snake River fall Chinook numbers fell to 78 fish in 1990, and Snake River sockeye salmon to less than ten adults per year, with only a single fish returning in 1992. Status reviews of the Columbia River listed salmonids were conducted recently by NOAA Fisheries and released in 2016. The reviews supported continued listing for all Columbia River ESUs. After 26 years from the first listing in the Columbia River, all 13 ESUs remain under ESA protection. The status reviews found that the same suite of causes that led to the decline and listing of the populations continues to impede their recovery. The continuing failure of the federal planning and recovery effort for Pacific Northwest salmon is a result of the chasm that exists between a hydro system trying to maximize power and profit over the salmon and steelhead ecological and life history needs. We are in an urgent situation. We need to stop looking for short-term fixes and instead invest in improved ecosystem function. Removing the lower Snake River Dams would open up access to the best and most climate-resilient salmon spawning habitat remaining in the continental United State.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Based on the fish analysis Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The CSS model predicts that average Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and would average above 2% (the lower end of Northwest Power and Conservation Council recovery targets for the region) as a result of the Preferred Alternative increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse negative unintended consequences, such as long delays of adult migrants, or total dissolved gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. The public trust doctrine grants states title to beds and banks of navigable waterways upon admission to the United States. Such navigable waterways are subject to an overriding Federal navigational servitude. That servitude underpins the United States' constitutional authority to construct, operate, and maintain the four lower Snake River dams, the public trust doctrine notwithstanding.
3970	13	Shelley Silbert	Great Old Broads for Wilderness	5. Modeling of Fish Populations is Incorrectly Described and Fails to State the Most Important Point A. The Comparative Survival Study Models are Incorrectly Described The description of Comparative Survival Study (CSS) models in the CRSO-DEIS Executive Summary (p. 12) is inconsistent with descriptions of the CSS models developed by CSS scient ist s29 . These descriptions are available to the public. Also, the statement that CSS models make specific assumptions about delayed mortality is false. A section of the Executive Summary briefly describes the NOAA COMPASS and LCM modelling and CSS modeling (CRSO-DEIS Executive Summary, p. 12-13). The description clearly highlights the fact that these are two very different modeling approaches. However, the Federal agencies have failed to point out a very important consideration in their discussion which is significant and should be emphasized in the Executive Summary. The CSS models which generate results in Smolt to Adult return rate, and the NOAA model which generates results in terms of arrival time to the estuary/ocean, both converge on the dam breach alternative. Whether in terms of smolt to adult return rate or arrival timing at the estuary, both modeling approaches converge on the dam breach alternative as the best option to affect both arrival time to the	Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-leads numerous legal obligations. The Preferred Alternative is predicted to benefit juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3 which includes breaching the four lower Snake River dams. However, the Preferred Alternative also meets most other EIS objectives including those for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS, the co-lead agencies did not recommend MO3 which includes breaching the four lower Snake River dams, because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies disagree that the CRSO EIS describes the CSS models inconsistently with published materials. The CRSO EIS describes how these different models predict different long-term survival benefits to ESA-listed species from dam breach, benefits that can contribute to recovery. Under the NMFS COMPASS model, juvenile Snake River spring/summer Chinook in-river survival would improve by 9.6% due to dam breach, which is a 19% relative increase over the No Action Alternative. The NMFS Life Cycle Model predicts an increase in adult returns of 13.6% for these same fish under MO3 (no latent mortality assumed) relative to the No Action Alternative (from 0.88% to 1%). Results for Snake River steelhead are

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				estuary and smolt to adult return rate. The document states the following: "CSS models treat the entire CRS as an aggregate of two routes of passage (number of powerhouses passed vs spilled on average). CSS models make statistical estimations of the effect of the freshwater CRS on latent ocean mortality" (CRSO DEIS, p. 3-359). The CSS cohort models generate five metrics including SARs, juvenile fish travel time, juvenile fish survival, ocean survival and in water transit time river ratio (Fish Passage Center 2020b). The CSS analyses indicate that the hydro system affects juvenile survival because spill and flow affect ocean survival, juvenile fish travel time, and juvenile fresh water survival. The CSS modeling does not make estimates of latent delayed mortality and the authors corrected observations on latent mortality in a memo30 .	similar (10% absolute improvement, or 23% relative juvenile survival increase -- Smolt-to-Adult returns (SARs) for steelhead were not modeled). Under the CSS model, juvenile in-river survival for the Snake River spring/summer Chinook is predicted to improve by 10.4% due to dam breach, which is an 18% relative increase over the No Action Alternative, while SARs would increase by 115% (from 2% to 4.2% 0.02 to 0.042). The CSS model predicts that Snake River steelhead would see juvenile survival increase by 25.8% which is a 46% relative increase over the No Action Alternative. The CSS model also predicts that SAR increase by 177% (from 1.8% to 5%). Though differing in predictions, both modeling groups predict dam breaching is the best CRSO EIS alternative for salmon and steelhead. One simply predicts adult return increases an order of magnitude higher than the other. These predictions are both discussed in the CRSO EIS, contrary to this comment.
3970	14	Shelley Silbert	Great Old Broads for Wilderness	B. The Comparison of the COMPASS and CSS Models Excludes the Most Important Point From Model Results. The discussion in the CROS-DEIS that compares COMPASS and CSS models excludes the most important point from model results (CRSO-DEIS, p. 3-362). The extensive discussion of comparison of NOAA COMPASS model results and CSS (collaborative agencies and tribes) model results is completely excluded from the discussion of model approaches. Although the CSS models are statistical empirical models based upon historic data, and the COMPASS model has a mechanistic structure, both models converge on one conclusion. The COMPASS model results attribute timing of juvenile fish to the estuary as a primary metric. The CSS model results include several metrics including SAR rates. However, both of these models agree that the most benefit (COMPASS arrival time to estuary and CSS Smolt to adult return rate) would result from breach of the four lower Snake River hydroelectric projects as discussed in MO3. This is the most important point in all of the discussion of model results and model structures, yet the federal action agencies have excluded this from discussion.	The EIS concluded MO3 would have greater improvement to certain salmon species in the lower Snake River. It did not conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Tthe co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
3970	15	Shelley Silbert	Great Old Broads for Wilderness	6. Alternatives are Confounded, Cryptic and the Range of Alternative is Inadequate A. The Development of Alternatives are Confounded and Difficult to Compare The "Development of Alternatives" is confounded and difficult to compare (CRSO-DEIS Executive Summary, p. 15). The co-lead agencies chose to develop alternatives that each had a different combination of proposed measures. Therefore the comparison of alternatives with each other is not possible. As an example, the Preferred Alternative is discussed as a continuation of the present Flex Spill Agreement, but it includes measures that are not part of the Flex Spill agreement such as draft of reservoirs below flood control elevations in the winter months, and additional irrigation water withdrawals from the Columbia River that total 1.254 million acre-feet. There is no common foundation to compare alternatives. The co-lead agencies chose "Multiple Objective Alternatives" (CRSO-DEIS, p. 2-2). These multiple objective alternatives include a myriad of actions, some designed to be beneficial to power production and irrigation to the detriment of objectives to recovery salmon and steelhead. Because each of these alternatives is a combination of many actions, there is no common foundation upon which to compare alternative actions to each other or to recover listed salmon and steelhead.	The CRS is a complex system with multiple purposes. The Purpose and Need Statement and the objectives developed for this EIS reflect these multiple purposes, as do the alternatives developed to meet them. This EIS was developed to evaluate the operation and maintenance of the CRS. Although fish and wildlife conservation is one of the authorized purposes, it is not the only purpose, and the co-lead agencies must consider how to seek to balance of all purposes. The analysis of the Multiple Objective alternatives (MOs) reflect these trade-offs and have allowed the co-lead agencies to understand the effects of emphasizing some purposes differently while seeking the most acceptable balance for future operations and maintenance. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. This EIS has been developed in consultation with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. As required by the National Environmental Policy Act (NEPA), the co-lead agencies evaluated each alternative for its effects on a suite of resources. These effects are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapters 3, 4, 5, 6 and 7; summarized by resource and alternative in Table 3-1, and presented for comparison in Table 7-1 in the Draft EIS. Effects specific to anadromous fish are described in Sections 3.5.3 and 7.7.4. In the Draft EIS, Table 3-61 compares expected survival by alternatives, and Table 3-62 provides a comparison of the alternatives specific to anadromous fish. The commenter incorrectly states that the Preferred Alternative diverts an additional 1.254 MAF for irrigation. The Preferred Alternative diverts an additional 45 KAF for irrigation, a substantially lower value than what was evaluated in the MOs. The intent of the Executive Summary is to serve as a primer and broad summary of findings. The Final EIS will expand the table of contents that was in the draft EIS to assist readers in finding specific topics. The EIS also includes an index, so the public knows where to look for detailed analysis in either the main body of the EIS or the appendices.
3970	16	Shelley Silbert	Great Old Broads for Wilderness	B. The Stated Anadromous Fish Goals are Cryptic The stated goals for salmon and steelhead are broad meaningless statements about improvement, and do not reflect the regionally established goal of a 4% average Smolt to Adult Return rate with a range of 2% - 6%. For example, Objective 1 is to "Improve ESA-listed anadromous salmonid juvenile fish rearing, passage, and survival within the CRSO project area through actions including but not limited to project configuration, flow management, spill operations, and water quality management" (CRSO-DEIS, p. 2-3). The regionally established SAR goals are clear, easy to understand and based on decades of scientific data and analyses. Cryptic, vague goals such as "improvement" will simply continue the status quo. The alternatives are a mixture of varying measures making meaningful comparison of alternatives difficult (CRSO-DEIS p. 2-3 to 2-4). The Preferred Alternative illustrates the problem of multiple and varying measures within alternatives. Although couched in terms of the present limited flex spill agreement, the Preferred Alternative includes actions that represent a decrease in protection for listed stocks from previous biological opinions. As a result, the Preferred Alternative does not actually represent the current flex spill agreement. Individual adverse actions to salmon and steelhead are included in some alternatives but not all alternatives, such as shifting flow from spring to winter by allowing additional reservoir draft below flood control elevations in winter at Grand Coulee, Libby and Dworshak reservoirs. The Preferred Alternative includes new additional irrigation withdrawals totaling 1.254 million acre feet in the upper Columbia which would reduce summer flows for migrating fall Chinook during the summer. It is important to note that NOAA BiOP summer flow targets are almost never met, so this proposal in the Preferred Alternative would adversely impact critical summer flows for fall Chinook. These examples of the Preferred Alternative illustrate that a more reasonable approach is needed, one that would compare all alternative actions based on the likelihood of recovering ESA-listed salmon and steelhead against the present hydro system operation. Providing a common foundation for comparison of proposed actions to recover listed salmon and steelhead is critical. Once a proposal to recover salmon and steelhead is identified, increasing the efficiency of dam operation for power and irrigation, power replacement, alternative port developments can be considered. The NEPA process is not invoked here to save the power system generation profits.	The 2-6% Smolt-to-Adult return rate (SARs) target referenced refers to the Northwest Power and Conservation Councils (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the fish analysis in Section 7.7.4, the Preferred Alternative will make a meaningful contribution to these goals, but the Councils broad sense recovery goals are beyond the scope of this EIS which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. With respect to the Preferred Alternative, the CSS model predicts that average SARs would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative increasing SARs from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of adverse negative unintended consequences, such as long delays of adult migrants, or total dissolved gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. It is the intention of the co-lead agencies to engage regional state, tribal, and Federal biologists in the development of an appropriate adaptive management process utilizing their respective salmonid management expertise. The goal of that adaptive management process would be to consider additional opportunities to further the effectiveness of the operation while maintaining the goals of the flexible spill operation: additional improvements for salmon and steelhead, maintain opportunities to operate the CRS for hydropower generation in a flexible manner that provides value to the Northwest, is implementable by the dam operators, and provides opportunity to reduce uncertainty and improve the learning opportunities around how operations of the CRS can influence the magnitude of latent mortality effects. The co-lead agencies have not made any determinations on what the preferred approach would be for a regionally developed study plan, and intend to develop that study jointly with regional experts. Unforeseen outcomes or unintended consequences will be monitored and adjusted using current in-season management teams such as the Technical Management Team. If no adaptive management needs are identified, the operation would continue through the duration of the ESA consultation period. The co-lead agencies have provided additional clarifying text in Appendix R to make these points more clearly. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The co-lead agencies completed consultation with the NMFS and U.S. Fish and Wildlife Service (USFWS) on the effects of the CRS on ESA-listed species, and the Biological Opinions are included in Appendix V of the Final EIS. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish resources in Section 7.7.4 for the Preferred Alternative, the co-lead agencies anticipate that the Preferred Alternative would provide meaningful benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The Preferred Alternative does not contain any proposed decreases to river flow levels that are expected to impact juvenile salmon migrating during spring and summer. Any changes in flow would be small enough to have minor to negligible impacts or occur outside of the juvenile migration season and are limited to areas of the basin where the impact would be negligible or minor. Effects from each alternative are summarized in Section 3 of the Executive Summary, fully described by resource and alternative in Chapter 3, 4, 5, 6, and 7 summarized by resource and alternative in Table 3-1, and presented for comparison in Tables 7-1 and 7-55 in the Draft EIS. Effects specific to anadromous fish are described in Sections 3.5.3 and 7.7.4 In the Draft EIS, Table 3-61 compares expected survival by alternatives, and Table 3-62 provides a comparison of the alternatives specific to anadromous fish. Lastly, the commenter incorrectly states that the Preferred Alternative diverts an additional 1.254 MAF for irrigation. The Preferred Alternative diverts an additional 45 KAF for irrigation, a substantially lower value than what was evaluated in the Multiple Objective alternatives.
3970	17	Shelley Silbert	Great Old Broads for Wilderness	B. The Range of Alternatives is Inadequate The scope of alternatives considered by the action agencies is inadequate (CRSO-DEIs, p. 2-5). Although the federal agencies selected a power production focused alternative in the range of alternatives (MO2), the federal agencies did not consider a salmon and steelhead focused alternative. The 2017 CSS Annual Report was presented to the co-lead agencies by the Fish Passage Center, and provided a range of 24 operations alt ernat ives. 31 The authors evaluated various BiOP spills of 115% forebay/120% tailrace, 120% tailrace, 125% tailrace, and each of these alternatives was compared with and without breach of the four lower Snake River Dams. These alternatives were considered based on present hydro system and reservoir operations. One of these alternatives was breach of the four lower Snake River Dams, and spill to the 125% tailrace TDG limit, 24 hours per day at the middle Columbia projects (Bonneville, The Dalles, John Day, and McNary Dams). This alternative should have been considered in the Draft CRSO EIS but was not.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The co-lead agencies are also required to evaluate a reasonable range of alternatives in the EIS. However, when there are potentially a very large number of alternatives, only a reasonable number of examples, covering the full spectrum of alternatives, must be analyzed and compared in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. Two of the objectives are directed at improvements for ESA-listed juvenile and adult anadromous salmonids. The agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% total dissolved gas (TDG) at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. MO3 and Multiple Objective alternative 4 (MO4), individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. Combining breaching the four lower Snake River dams with spill up to 125% at the lower Columbia River projects is not a reasonable alternative under National Environmental Policy Act (NEPA). For power and transmission, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major additional new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two Multiple Objective alternatives (MOs) individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and was not proposed as an alternative.

3970	18	Shelley Silbert	Great Old Broads for Wilderness	7. There are Many Misleading and False Statements in the CRSO-DEIS; Only Four Examples are Presented Below but There are Many More A. Downstream Juvenile Dam Survival Estimates in the CRSO-DEIS are Misleading. The co-lead federal action agencies should refrain from misleading statements about dam passage and survival. For example dam survival estimates are disingenuous (CRSO-DEIS, Executive Summary, p. 19). Figure Executive Summary ES-4 (the same Figure 3-113, p. 3- 302) is designed to mislead the public and fails to explain that dam survival is multiplicative.; that is, total survival through the hydro system from the Snake River to below Bonneville Dam is typically around 50%. Data on juvenile fish survival through the Snake and Columbia Rivers are easily accessible and available to the public for specific populations of salmon and steelhead. The representation in Figure ES-4 and Figure 3-113 specifically refers to "performance standard" testing at projects in 2010-2014. The inadequacies and issues associated with those performance standard tests affecting the validity of results are a matter of public record. As an example, using the chinook numbers in Figure ES-4 and assuming 98% survival for Ice Harbor Dam would imply that survival through the Lower Granite and Ice Harbor reaches would be 96%. However, juvenile survival through this river reach averages 72%. The performance standard concept and approach is fatally flawed because it does not account for decreased estuary and ocean survival resulting from powerhouse passage of juvenile salmon and steelhead. The actual reach survival rates are available, and should be incorporated into the Final EIS rather than giving false information. Similarly, the CRSO-DEIS claims that "To aid the downstream passage of juvenile salmon and steelhead, the co-lead agencies have worked to improve passage and survival past the dams and through the reservoirs of the CR" (CRSO-DEIS, p. 3-301). This figure gives overly optimist estimates of fish survival since it fails to show systemwide or latent effects on migrating fish. The CRSO-DEIS states that "In general, bypass and spillway routes are associated with relatively higher juvenile salmon survival than turbines routes. Spill levels, spill patterns, and turbine priorities also have significant effects on the survival rates of migrating juveniles via their influence on tailrace hydraulics and the formation of eddies" (CRSO-DEIS, p. 3-370). As a result, alternatives that route more fish through turbines would be associated with lower juvenile survival. Currently, between 48% - 82% percent of all juvenile salmon pass dams via spillway routes.32 Studies to evaluate route specific survival show that survival rates from spillway routes ranged from 96% to 100%. The CRSO-DEIS also states that "The adverse impact of past Columbia River System operations has been reduced over time, and multiple mitigation actions have improved habitat, hatchery operations, and predator management, thus increasing survival rates of individuals in these ESUs, reducing extinction risk, and thereby contributing to improvements in the likelihood of recovery" (p. 3-304). Data show that survival rate increases are miniscule, and still average 50% from Lower Granite to Bonneville. There are also latent effects of the hydro system that further diminish survival to often less than 20% by the time juvenile fish reach the ocean. These data are reflected in the SARs which show that Snake River anadromous fish generally have less than 1% SARs, and are continuing to slide toward extinction. Statements in the DEIS like the above demonstrate that tweaking the system over and over again has failed to make substantive changes in SARs, and that Snake River salmon and steelhead are likely headed towards extinction unless measures such as dam removal are implemented within the next five years.	Survival through the CRS dams is presented in Sections 3.5 and 7.7.4 and includes survival through the multiple dams as well as reservoirs. Even without dams and reservoirs, there would be some level of natural mortality of juveniles migrating in-river. The co-lead agencies presented factual information in the Draft EIS, and did not include information intended to "mislead" the public as the comment suggests. Latent effects were considered and factor prominently in the identification of the Preferred Alternative. The Preferred Alternative is not simply tweaking the system. The spill operation for juvenile fish passage in the Preferred Alternative is a significant departure from previous operations, so much so that the Washington and Oregon state water quality standards had to be changed to implement the new spill regime. The CSS model, which includes latent mortality effects, predicts that median Smolt-to-Adult return rates will increase for both Snake River spring Chinook and steelhead and will average well above 2% (the lower end of Northwest Power and Conservation Council's recovery targets for the region) as a result of the Preferred Alternative. The National Marine Fisheries Service (NMFS) COMPASS and Lifecycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. To address uncertainty highlighted by the two models, the Preferred Alternative includes working with regional sovereigns to develop a study that assesses the effectiveness of the increased spill regime on adult returns as well as assessment and management of negative unintended consequences, such as long delays of adult migrants, or total dissolved gas (TDG)-related mortality of juvenile migrants. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The co-lead agencies completed consultation with the NMFS and U.S. Fish and Wildlife Service (USFWS) on the effects of the CRS on ESA-listed species, and the Biological Opinions are included in Appendix V of the Final EIS.
3970	19	Shelley Silbert	Great Old Broads for Wilderness	B. The Preferred Alternative Overstates the Benefits of the Preferred Alt ernat iv e. Descriptions of benefits from the Preferred Alternative are extremely misleading and overstate the potential benefit of the Preferred Alternative (CRSO-DEIS, Executive Summary, p. 33). The discussion of the Preferred Alternative includes discussion of Comparative Survival Study model results of alternatives, stating a 35% and 28% benefit to Chinook and steelhead SARs respectively. The discussion is disingenuous and extremely misleading to the public reader of this draft EIS. A Fish Passage Center memo to the federal co-lead agencies presented the results of CSS model analyses of DEIS alternatives including the Preferred Alt ernat ive 33 . A review of the data tables in the numerous appendices of this memorandum revealed that the percent benefit described in the Executive Summary is derived from Comparative Survival Study (CSS) model analysis of the Preferred Alternative. The authors divided the average SAR predicted for the Preferred Alternative by the average SAR predicted for the No Action Alternative, and this resulted in the 35% and 28% benefit from the Preferred Alternative. This is a relative benefit and should be identified as such. A 35% relative increase of a small number still results in a small number. Most importantly, the same tables in the same memo to the co-lead agencies showed that neither the Preferred Alternative nor the No Action Alternative meet the regional 4% average SAR regional goal for recovery. The average Chinook SAR predicted for the No Action Alternative is 2%, while the average under the Preferred Alternative is 2.7%. Both results are far from the goal of a 4% regional average . More disturbing is that the Executive Summary fails to discuss that the same CSS analyses of the Preferred Alternative shows that at the lower quartile range, the prediction in this analysis is less than 1% SAR, well below the SAR needed for salmon and steelhead population replacement. Under increasing climate change conditions the lower quartile of the range represents poor ocean conditions and poor flow conditions that will occur more often. In other words, populations are likely to decline and go extinct under both the No Action and Preferred Alternatives.	The co-lead agencies contracted with the Fish Passage Center (FPC) to produce the CSS modeling results presented in the Draft EIS. The commenter correctly concludes that the percent benefit figures are derived from the CSS results. These are presented in Section 3.5 tables for each species as a percent change from the No Action Alternative (NAA) in the Draft EIS. Also presented are the median and average values for other metrics modeled, such as in-river system survival, proportion of powerhouse passage, total dissolved gas (TDG) exposure, etc. The co-lead agencies highlighted the more relevant metrics in the Executive Summary: median Smolt-to-Adult return rates (SARs) and their percent change from the NAA. When referencing these Preferred Alternative fish results the co-lead agencies are using language similar to this to help clarify any potential misunderstandings: The Preferred Alternative increases SARs from 2.0% to 2.7% for Chinook, a 35% relative increase. Regarding the extinction risks and the regional 4% SARs goal comment, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. Moreover, the 4% average SARs target referenced refers to the Northwest Power and Conservation Councils target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. Based on the anadromous fish analysis in Section 7.7.4, the Preferred Alternative would make a substantial contribution, but the Councils broad sense recovery goals are beyond the scope of this EIS, which contemplates the effects associated with the operation and maintenance of the 14 CRS projects.
3970	20	Shelley Silbert	Great Old Broads for Wilderness	C. Adult Migration Delays Due to Spill Claims are Unfounded The CRSO-DEIS claims that adult migration delays occur due to higher spill conditions (CRSO Executive Summary, p. 330) are unfounded. The CRSO-DEIS claims that "In general, higher flows and higher spill levels lead to longer migration timing and can contribute to site specific delays for adult salmonids through the CRS projects" (CRSO-DEIS p.3-371). The Preferred Alternative increases spill at the four lower Snake River Dams for only 16 hours per day. The largest factor affecting upstream adult migration success and delay is the juvenile smolt transportation program. Upstream migration delay and success should be improved by eliminating the juvenile smolt transportation program. Also, the CRSO-DEIS fails to address the improvement in adult upstream migration that would occur as a result of dam breaching.	There is strong evidence that higher flow and higher spill (which often go together) are significantly correlated with slower migration rates for spring/summer Chinook salmon while steelhead and fall Chinook salmon, which predominately migrate during periods of little to no spill, are more influenced by water temperatures (Bjornn et al. 2000; Keefer et al. 2004; Keefer et al 2005a). At specific dams, passage times have been found to be higher during higher spill conditions (Bonneville Dam, Caudill et al. 2006; Little Goose Dam; Harnish et al. 2019; Jepson et al. 2009; Lower Monumental Dam, Keefer et al. 2006). In addition, all salmon species' migration rates are significantly slower for fish that fall back at dams and fallback is higher at higher spill (Bjornn et al. 2000; Bjornn et al. 2001; Boggs et al. 2005; Keefer at al. 2002; Keefer et al. 2004; Keefer at al. 2005a). While fish that were transported as juveniles can experience higher straying and fallback behavior than fish that were not transported (Keefer et al. 2008), overall stray rates are relatively low for adult migrants (2.2% of springsummer Chinook salmon, 4.2% of fall Chinook salmon, and 6.8% of steelhead strayed into non-natal tributaries overall; Keefer et al. 2005b). As most smolts migrate in-river and most transported fish do not stray or fallback, the commenter's statement The largest factor affecting upstream adult migration success and delay is the juvenile smolt transportation program. is not supported by references cited and conflicts with the sources utilized in the Draft EIS (complete citations below). 3970	21	Shelley Silbert	Great Old Broads for Wilderness	D. Combined Annual Salmon and Steelhead Returns (all species) to Bonneville Dam from 1938- 2019 Mispresents Anadromous Fish Population Abundance The Figure 3-111 (CRSO-DEIS, p. 3-300) is misleading to the public (Figure 6). In this figure all species and all populations are combined into total counts at Bonneville Dam, and the discussion relative to this figure refers to NOAA's status of stock evaluat ions. This figure should be eliminated and replaced with figures of smolt to adult return rates for individual species and populations such as Snake River sockeye, Snake River steelhead, Snake River spring/summer Chinook and Snake River fall Chinook. Also, wild population data should be shown separately and not added to hatchery data. Increasing numbers of hatchery fish reared and added to the river can mask effects on wild populations. Populations of wild salmon and steelhead from the John Day and Yakima Rivers pass only three and four dams, respectively, and their SARs meet the regional 4% average most of the time. These populations, as well as populations of salmon and steelhead from other middle Columbia tributaries and major middle Columbia hatchery programs, are combined with poor adult returns to the Snake River and Upper Columbia rivers in the Bonneville Dam counts in Figure 6 (Figure 3-111 in the CRSO-DEIS). Mixing of these data hides the true impact of dams on Snake River ESA-listed salmon and st eelhead . [graph included in document: Combined Annual Returns of Salmon and Steelhead to Bonneville Dam] Figure 3-111, Combined Annual Salmon and Steelhead Returns (all species) to Bonnev ille Dam from 1938-2019. Figure 6. Figure 3-111 in the CRSO-DEIS of Adult Returns of all Salmon and Steelhead Species to Bonneville Dam from 1938 to 2019; includes combined hatchery and natural origin fish. (Data Source: University of Washington) (CRSO-DEIS, p. 300). The graph above implies to the public that salmon and steelhead are doing well and have not been impacted by the Columbia and Snake River dams. The following three graphs tell the real story about declines in salmon and steelhead in the Snake Ri ver with severely declining abundance of Snake River Adult Returns for wild Spring/Summer Chinook sal mon, sockeye salmon and steelhead: 1950s to 2019 (Figures 7-9)34 . Wild stocks of Chinook and sockeye salmon and steelhead are declining dramatically and urgent substantive action is needed to reduce their risk of extinction and restore their abundance to sustainable	The co-lead agencies respectfully disagree that Figure 3-111 on page 3-300 is either inaccurate or misleading. The title is "Combined Annual Returns of Salmon and Steelhead to Bonneville Dam 1938-2019." The caption reads: Figure 3-111. Combined Annual Salmon and Steelhead Returns (all species) to Bonneville dam from 1938-2019. The returns portrayed in this figure are a combination of hatchery and natural origin fish. (data Source: University of Washington-Data Access Real Time (DART) tool). This figure is part of a general overview of anadromous fish in the study area. The later Sections of the report do break out analyses and discussion by species and origin. The comment incorrectly implies that hatchery fish are not relevant to the Draft EIS. Hatchery origin fish are very important to Tribal and sport harvest in within the CRB, and many hatchery programs are important supplementation to rebuilding natural populations. The listings for several evolutionary significant units for salmonids include hatchery origin fish in the listing. Further, the three co-lead agencies have legal requirement to produce hatchery fish as mitigation for components of the CRS. The co-lead agencies used high quality information and best science in the analysis of the CRSO EIS. Specific to salmon and steelhead, the agencies used two primary modeling approaches which yielded a range of potential outcomes for the alternatives. With respect to the Preferred Alternative, the CSS model predicts that average Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative increasing SAR from 2.0% to 2.7% for Chinook, a 35% relative increase. The co-lead agencies disagree with the comment that notes a SAR of 2% will only maintain a population. A SAR rate of 2% can lead to significant population growth given adequate productivity and habitat quality. The COMPASS and NMFS Life Cycle models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. In relation to the comment that fish passing few dams have higher SARs and survival, the co-lead agencies follow the guidance from the Independent Science Advisory Board, to do not typically weigh performance of one population vs. another. It is difficult to isolate causative factors in those types of comparisons (ISAB 2020-1).

				levels. [graph included in document: Wild Snake River Adult Spring/Summer Chinook] Figure 7. Wild Snake River Spring/Summer Chinook adult returns from 1954 to 2019. Historic annual Spring-Summer Chinook returns to the Snake River Basin were 2 million fish. Snake River Spring/Summer Chinook were ESA-listed in 1992 . [graph included in document: Wild Snake River Steelhead] Figure 8. Wild Snake River steelhead adult returns 1962 to 2017. Historic annual steelhead returns to the Snake River Basin were 1 million adults. Snake River steelhead were ESA listed in 1997. [graph included in document: Wild Snake River Sockeye] Figure 9. Wild Snake River sockeye from 1954 to 2019. Historic annual sockeye salmon returns to the Snake River Basin were greater than 100,000 fish to Central Idaho's high mountain lakes. Snake River sockeye was listed in 1991	
3970	22	Shelley Silbert	Great Old Broads for Wilderness	E. The CRSO-DEIS fails to Acknowledge the Importance of Restoration of Historic Spawning Habitat, Wetlands and Floodplains from Dam Breaching. The CRSO-DEIS states that "In Region C [which includes the Snake River], vegetation, habitat, and wildlife along the existing shorelines would either be lost or change how wildlife utilize the area. The CRSO-DEIS claims that new vegetation and habitat types along new shoreline would be added with dam breaching, resulting in negligible beneficial effects and major negative effects. Negligible effects on floodplains in Regions A, B, and D, with major beneficial effects in Region C below Dworshak Dam" (CRSO-DEIS, Table 3-1, p. 3-8). The CRSO-DEIS fails to acknowledge the importance of restoring fall Chinook spawning habitat and 15,000 acres of prime riverine habitat and agricultural land that is inundated by the lower Snake River dams.	If breaching were to be selected as part of the Preferred Alternative, further evaluation, studies, and NEPA would be needed along with congressional authorization and appropriations to assess the requirements of the project and would develop and analyze alternatives for land use and management. Please refer to Section 3.5 for discussions of fall chinook spawning habitat. For MO3, Section 3.6 describes the habitats that would be altered by the breaching of the four lower Snake River dams. Section 3.6 did not discuss agricultural land as a cover type because whether that is the future cover type for inundated areas below the current reservoir surface elevation would be determined during real estate transactions. The co-lead agencies do not manage agricultural use of those areas and most likely, if those uses were to return, it would be through real estate transactions. The riverine habitat is also speculative, given years of sediment accumulation and the unvegetated nature of what is now river bottom. Section 3.5.3.6 under the Larval Development/Juvenile rearing sub-heading (line 17110) of the Draft EIS describes that breaching the four lower Snake River Dams is estimated to increase the available spawning habitat for fall-run Chinook from 226 acres to 3,521 acres, an increase of 15 times the area available today. Shallow water rearing habitat is very important to juvenile Fall Chinook. The Final EIS has been updated to more clearly articulate this. Section 3.5.3.6 under the Larval Development/Juvenile rearing sub-heading (line 17110) of the Draft EIS describes that breaching the four lower Snake River Dams is estimated to increase the available spawning habitat for fall-run Chinook from 226 acres to 3,521 acres, an increase of 15 times the area available today. Shallow water rearing habitat is very important to juvenile Fall Chinook. The Final EIS has been updated to more clearly articulate this.
3970	23	Shelley Silbert	Great Old Broads for Wilderness	F. The CRSO=DEIS Misleads the Public by Claiming that the Historical River Temperatures in the Snake River Exceeded the 68F (20Q Standard The CRSO-DEIS states that: "Historical temperatures in the lower Snake River Basin prior to the construction of the lower Snake River Dams and the Hells Canyon Complex show that temperatures in the free-flowing lower Snake River often exceeded 68F/ 20C in July and August and occasionally exceeded 77F/25C. These measurements were taken near the mouth of the Snake River from 1955 to 1958 (Peery and Bjornn 2002)" (CRSO-DEIS p. 3-238). The CRSO-DEIS does not discuss that this area had already been largely impacted by upstream USACOE dams and other dams that affect water temperatures. The Fish Passage Center reported that "The construction of the hydropower system dramatically increased the cross - sectional area of the river, greatly slowing water velocity and slowing fish downstream travel time." This is a critical omission in this paragraph because one of the major benefits of breaching the four lower Snake River Dams is that water velocity would be much faster after breach. As a result, fish travel time would be much faster which would mean that juvenile fish would arrive at the estuary much earlier" 35 . EPA modeling showed that, when considered collectively, the four lower Snake River Dams can affect temperatures up to a potential maximum of 6.8C/12.2F 36 . More recent analyses clearly demonstrate the benefits of dam removal on lowering temperatures by changing backwater reservoirs from wide, slow-moving reaches to a free-flowing river37 . Schultz and Johnson's analyses showed that each dam of the four increased water temperatures by 2-4F /1.1-2.2C.	Historical water temperature measurements were collected from 1955 to 1958, which are reported in the EIS. This information helps to build historical context and provide an idea of what water temperatures would have looked like prior to the construction of the four lower Snake River and Hells Canyon Complex dams. The four lower Snake River dams include Lower Granite Dam (constructed in 1975), Little Goose Dam (constructed in 1970), Lower Monumental Dam (constructed in 1969) and Ice Harbor Dam (constructed in 1961), while the Hells Canyon reach dams include Brownlee (constructed in 1959), Oxbow Dam (constructed in 1961) and Hells Canyon Dam constructed in (1967). No Corps of Engineers dams existed on the Snake River prior to 1961. The fish benefits of breaching the four lower Snake River dams are discussed in the analyses of Snake River salmon and steelhead in the Section 3.5 of the Draft EIS. Faster travel times, among other parameters such as temperature differences, under a breach scenario were incorporated into both models that were used to estimate juvenile survival and, as reported in the Draft EIS, both indicated higher juvenile survival than the No Action Alternative. For Snake River Spring/Summer Chinook salmon, decreased travel time of 4.5 days and 5.5 days, respectively, were indicated by CSS and COMPASS models, as compared to the No Action Alternative. The water temperature model used to analyze all EIS alternatives underwent significant review by experts outside of the co-lead agencies, including scientists from the United States Environmental Protection Agency (USEPA), U.S. Geological Survey (USGS), and Portland State University. In addition, the USEPA and co-lead agencies worked together to compare the co-lead agencies' CE-QUAL W2/RAS model (used for EIS analysis) and the EPA's RBM-10 model (used for the TMDL assessment). Efforts included identifying and comparing similarities and differences in the two models and assessments, and concluded that both models provide useful and technically appropriate analyses of the Columbia and lower Snake River water temperatures. As such, the EPA agreed with the co-lead agencies that the CE-QUAL W2 and HEC RAS models are appropriate to use in developing the Draft EIS (see EPA review comment letter # 16-0059).
3970	24	Shelley Silbert	Great Old Broads for Wilderness	G. The CRSO-DEIS Misleads the Public by Claiming that Breaching will Causes Severe Short-Term Impacts The CRSO-DEIS claims that "Short term effects include high sediment and low oxygen concentrations that would likely lead to the loss of most of the fish in this reach during breaching, reduced forage and productivity for 2 to 7 years following breaching, and potential migration barriers at tributaries that may become perched during reservoir drawdown"(CRSO DEIS, p. 3-586). This has not been borne out by the many dams removed across the nation, including many that were 100 - 200 years old and had accumulated large amounts of sediment and toxins. Done carefully and at the correct time, dam removals have repeatedly demonstrated success in restoration of anadromous fish on the East and West coasts of this country.	As detailed in Chapter 2, the formulation of the drawdown and embankment removal plan associated with MO3 and breaching the four lower Snake River dams mirrored the plan developed in the 2002 Lower Snake River FR/EIS. Sediment loads to the Snake and Columbia Rivers that could occur under the MO3 under the Breach Snake Embankments measure were analyzed using water quality and sediment transport models as described in Appendices B & C. These analyses considered physical and chemical data, river bathymetry and hydrology, and other data specific to the lower Snake River. The sediment impounded behind the four lower Snake River Dams is predominately fine grained and readily transported in suspension. Analysis results for the MO3, under the Breach Snake Embankments measure indicate that increased sediment concentrations could occur during the construction season with impacts to dissolved oxygen as described in Section 3.4.1 of Appendix C. Mitigation actions to address these potential impacts are described in Chapter 5.4.3. Modeling suggests that impounded sediments within the historical river channel extents would scour back to the historical river-bed elevations over the near-term depending on the magnitude and duration of watershed hydrology. Impounded margin sediments remaining on higher elevation floodplain terraces would be expected to incrementally erode over a longer decadal time frame as seasonal floods access those surfaces. More detailed analyses to optimize the embankment removal plan (means, methods, timing, etc.) to minimize impacts and manage sedimentation could be conducted under a future environmental analysis, if dam breach was selected as the Preferred Alternative. Many dam removal projects that have occurred across the United States have very different circumstances than what is contemplated in MO3. The Elwha dam in Washington State, for example, has little relevance to the lower Snake River dams. The Elwha Dam had no fish passage and provided no economic benefits. In contrast, the four lower Snake River dams provide upstream and downstream fish passage, produce power, and provide navigation and recreation opportunities. For power, the four lower Snake River dams produce roughly 1,000 aMW of power, which is approximately 11 percent of the average power produced by the Federal Columbia River Power System. See Draft EIS, Section 3.7.3.5, Changes in Power Generation, Table 3-159. Losing this amount of power is equivalent to losing power capable of serving 730,000 homes in the Northwest. See Draft EIS, Section 3.7.3.5, Summary of Effect, at 9-935. The four lower Snake River dams would still have regulated flows due to the dams located upstream. A good information source related to removal of the Elwha and Glines Canyon Dams on the Elwha River is the National Park Services website on restoration and current research (https://www.nps.gov/olym/learn/nature/restoration-and-current-research.htm, accessed 5-25-2020). Findings in several research areas are summarized. On the topic of Sediment and Hydrology: Damming of the Elwha River dramatically reduced sediment flow to the coast leading to rapid erosion of the shoreline of the Elwha River delta. Removal of the dams has resulted in the release of millions of cubic yards of sand and silt to the nearshore waters of the Strait of Juan de Fuca. Specifically, sediment released during dam removal resulted in over a meter of sedimentation in the estuary and over 400 meters of expansion of the river mouth delta landform. Mitigation actions to address these potential impacts are described in Chapter 5.4.3. Modeling suggests that impounded sediments within the historical river channel extents would scour back to the historical river-bed elevations over the near-term depending on the magnitude and duration of watershed hydrology. 3970	25	Shelley Silbert	Great Old Broads for Wilderness	8. Climate Change is Causing and Will Continue to Increase the Risk of Extinction of Snake River Anadromous Fish Although the discussion of impacts of climate change is extensive, the Federal agencies have not included results of model analyses regarding climate change co nditions and smolt to adult returns (CRSO-DEIS, Chapter 4, p. 4-1 to 4-82). The chapter on climate change discusses expected changes to reservoirs and outflows due to climate change, but fails to discuss and even dismisses CSS analyses submitted to the Federal action agencies on January 24, 2020 38 . The Fish Passage Center data show predicted SARs in the lower quartile results, which represent poor ocean conditions and low flows which will occur more often than has occurred in the historic data time series. These analyses indicate that under climate change conditions, only the dam breach options predict SARs above 1% to avoid population decline. It is obvious that under climate change conditions, maximum spill and dam breach are required to increase juvenile survival and decrease delayed mortality. Although there is much discussion of climate change on hydro power production, there is no quantitative discussion of the impact of climate change on Snake River salmon and steelhead. The CSS results indicate that dam breaching is the only alternative that has the potential to maintain Snake River salmon and steelhead populations under poor ocean and flow conditions expected with climate change. In a letter to the West Coast Regional NOAA Fisheries M anager39 it was reported that the Northwest Power Council's Independent Science Advisory Board {ISAB) warned over a decade ago, in its report "Climate Change Impacts on Columbia Basin Fish and Wildlife," 40 that the impacts of climate change on Columbia Basin salmon would be profound. Even in 2007, these impacts were not obscure or unknown - warming water temperature, alterations in river and stream flows, and reduced ocean productivity were all effects that had been identified and document ed. Indeed, many of the scientific studies of these effects cited in the ISAB's 2007 review date back to the 1990s. Climate change further compounds the need for additional substantive measures for native anadromous fish restoration in the Snake River and its tributaries. Climate change will affect river and stream flow and water temperatures in the coming decades. Climate change affects on hydrology will include decreased snowpack, earlier snowmelt, earlier runoff, and potentially slightly more precipitation. Peak flows will be higher and summer low flows lower compared to existing conditions. With climate change trending towards warmer and drier conditions in the Pacific Northwest, "Summer base flows will be lower , and the network of perennially flowing streams in a drainage system will shrink during the summer dry period, forcing fish into smaller wetted channels and less diverse habitats" . An independent climate expert from the Climate Change Resource Center and the ISAB predicted that "Trout and salmon within the interior Columbia River Basin may be especially sensitive to climate change... Although the intensity of the effects will vary spat ially , climate change will alter virtually all streams and rivers in the basin. Current predictions suggest that temperature increases alone will render 2% - 7% of headwater trout habitat in the Pacific Northwest unsuitable by 2030, 5% - 20% by 2060, and 8% - 33% by 2090." ESA-listed fish species are already at risk due to cumulative impacts	Through on-going regional climate change studies and work, the co-lead agencies evaluated potential shifts in precipitation and temperature patterns and resulting changes in unregulated Columbia Basin streamflow timing and volumes. The evaluation consisted of the full range of the latest climate change projections developed using multiple global climate models, emissions scenarios, downscaling techniques, and hydrologic models. Details of this evaluation are in Chapter 4 of the EIS. This information was used to describe the potential effects (both beneficial and adverse) on the river systems and resources due to potential changes in climate for all alternatives. Quantitative data that describes how climate change hydrology will affect reservoir operations in the Columbia Basin in still under development and was not available for this EIS. The climate science community is still developing quantitative models that can address possible effects in water temperature from climate change, and unfortunately, there are not reliable models at the resolution (river-scale vs. global- or regional-scale) at this time. This data is critical to analyzing potential effects to fish quantitatively. In lieu of this information, the climate analysis used the output from resource models, like water quality and fish, under historical conditions, available climate change data, and scientific literature to qualitatively assess potential effects to resources (described in Chapter 4; see Section 7.8 for the climate effects under the Preferred Alternative). Hatchery programs have long been a part of the approach for salmon recovery. There are broad ecological effects concerning interactions of wild and hatchery fish, as well as harvest, throughout the basin. However, the actual mechanisms, effects, magnitudes, and processes are very complex and uncertain. The analyses used in the CRSO Draft EIS were for the purposes of comparing the effects of the Multiple Objective alternatives for operation, maintenance and configuration of the CRS projects to one another and to the No Action Alternative. Hatchery origin fish are very important to tribal and sport harvest within the Columbia River Basin, and many hatchery programs are important supplementation to rebuilding natural populations. Further, the co-lead agencies have legal requirements to produce hatchery fish as mitigation for components of the CRS. The effects of hatchery programs on ESA-listed fish are evaluated through individual consultations under the Endangered Species Act. These consultations ensure the hatchery programs are not appreciably reducing the likelihood of ESA-listed species survival and recovery, nor adversely modifying or destroying designated critical habitat. These consultations have resulted in many site-specific reforms to reduce effects of hatchery/wild fish interactions, such as decreasing the temporal and spatial overlap of wild and hatchery fish in integrated programs or transitioning to local broodstock in integrated programs.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				from dam and reservoir passage mortality and t hermal regimes that cause chronic and acute mortality. With declining flow and warmer temperatures predicted in the coming decades, the Preferred Alternative largely ignores probable climate change impacts on fish in the Columbia and Snake River Basins. Extreme climate events such as drought, and ecological disturbances such as fl ooding, wildfire, and insect outbreaks are expected to increase. The ISAB reported that the evidence includes increases in global average air and ocean t emperat ures, widespread melting of snow and ice, and rising global mean sea level. Further, the ISAB predicts that salmon habitat loss would be most severe in Oregon and Idaho with potential losses exceeding 40% by 2090. However, recent research indicates that climate change is accelerating faster than earlier predictions from the ISAB (Figure 10) . [figure included in document: Reduced summer Flows] Figure 10. Projected changes in water runoff and streamflow for 2040, as compared to 1915- 2006 from the Climate Reality Project. Experts on climate change evaluated the vulnerability of salmon and steelhead stocks on the West Coast 45 and reported that "geographical patterns indicated a potential range contraction toward the coast for anadromous life histories unless access to higher-elevation habitats is restored and habitat quality in rearing areas and migration corridors is improved." The authors reported that Interior Columbia Chinook salmon had the highest vulnerability scores, and also face the largest percentage loss of snow-dominated habitat. The authors stated that reducing anthropogenic stressors would greatly improve responses to climate change by improving the overall status of these species in terms of abundance, productivity, spatial structure, and diversity. They also stated that reconnection of habitats blocked by artificial barriers, either longitudinally or laterally {floodplains), has been successful in expanding the effective climate space of a watershed. The authors recommended improvement of temperature or flow constraints to help reduce climate stresses. They suggested dam removals can be effective, and cited dam removals in recent years where salmon abundance and distribution {e.g., in the Elwha, Rogue, White Salmon, Sandy, and Carmel Rivers) has responded even more rapidly when multiple dams were removed {such as in the Rogue, Sandy and Elwha River basins). Climate experts on salmon and steelhead vulnerability also state that "Hatchery supplementation can reduce fitness in wild salmon populations both through introducing maladaptive genotypes and reducing the effective population size of wild populat ions. Therefore, reducing the number of hatchery-origin fish in general can be expected to improve the adaptive capacity of wild populations in the face of increasing exposure to climate cha nge." They acknowledge that in highly endangered populations (such as Snake River sockeye) hatcheries can provide a temporary buffer from extinction risks. The authors very specifically stated where dams block passage and interrupt ecological and physical processes, dam removals will likely result in habitat that diverges less from those seen historically and reduce impacts of climate change for fish at all life stages. They noted that recent dam removals and restoration activities had demonstrated reconnected floodplains, and that physical and ecological responses can be rapid and effectively reduce habitat constraints.	
3970	26	Shelley Silbert	Great Old Broads for Wilderness	9. Summary of Fish and Aquatic Concerns In summary, the Great Old Broads for Wilderness support the M03 Alternative (breaching the four lower Snake River Dams) in combination with the M04 Alternative {125% TDG) spill at the remaining dams on the Columbia River. The four lower Snake River Dams must be breached immediately to provide wild salmon runs on the Snake River the best chance to recover. Millions of dollars are spent by the federal agencies annually on salmon recovery measures. Yet all the experimentation with fish passage, barging, massive hatchery programs, and more have not worked. All options have been explored, and there are no solutions for the four deadly slack water reservoirs behind the Snake River Dams. Dam breaching makes both economic and ecological sense. It provides wild salmon and steelhead the best opportunity to survive and recover, and will bring back to health the ecosystem that depends on these keystone species. The past decades have shown that throwing money at the dams in the hope that wild salmon will recover does not produce results and is a waste of tax and rate payers' money. It's time to truly balance fish recovery with other hydro system benefits. It's time to remove the lower Snake River Dams and initiate high levels of spill at the remaining Columbia River Dams.	As addressed more fully in a prior response to a similar comment from your organization, the agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% total dissolved gas (TDG) at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. If MO3 were selected, the Corps could use this EIS as a basis for seeking congressional authority to breach the four lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species.
3970	27	Shelley Silbert	Great Old Broads for Wilderness	1, The CRSO-DEIS's Findings and Conclusion on Sensitive Species Effects of M03 and Its Biological Assessment for Southern Resident Killer Whales are Flawed, as They Rely on Erroneous and Outdated Data and Speculative Mitigation Measures and Fail to Use Current and Best Available Science. Unfortunately, the DEIS fails to recognize the worldwide interest and irreplaceable value of these unique sea mammals, nor does it use current scientific data that are crucial to preserving this small, unique, ESA-listed Distinct Population Segment (DPS) The CRSO-DEIS's findings and conclusion about the impact of MO3 on the Southern Resident Killer Whale (SRKW) DPS are incorrect. Table 3-106, Sensitive Species Analysis for MO3 (p.3-759) states, "Prey Availability: Minor effect. The Snake River spring/summer Chinook salmon is a negligible portion of their overall diet." These findings ignore the important nutritional role of Snake River chinook salmon runs during critical winter and spring feeding times for SRKWs, as discussed in more detail below. Similarly, the conclusion that MO3 would have a "minor effect" on SRKWs is wrong. The CRSO DEIS states as support for this conclusion: "The food available to Southern Resident killer whales from the lower Snake River population is only a small percentage of their overall diet. Changes to food availability may change the whale's foraging behavior patterns slightly but will not change their overall condition or population dynamics." That statement is inaccurate according to the best available science discussed below. It fails to take into account how a substantially increased supply of nutritious, large Snake River chinook salmon is literally a matter of life and death for these starving, critically-endangered orcas."	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. SRKW analysis has been described in the EIS, including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The SRKW analysis considered spring and fall Chinook within the Columbia River to be food sources for the SRKW. MO3 causes moderate increase to these two ESUs. This would cause a minor effect in SRKW food sources. The ocean factors are a major component of the condition and availability of the salmon to SRKW that needs further study. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants as noted in the comment. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain mitigation measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
3970	28	Shelley Silbert	Great Old Broads for Wilderness	Similarly flawed is the Action Agencies' Biological Assessment (BA) (found in Appendix V, Section 3.5.1.2, pgs. 3-598-3-600). After reviewing the status, habitat and foraging of SRKWs, the BA concludes,"Any remaining Chinook mortality attributable to the Proposed Action is only a subset of the total mortality from all sources within the mainstem migratory corridor. Therefore, the Action Agencies have determined that management of the CRS may	The Biological Assessment (BA) describes the effect of the Proposed Action (PA) on the Southern Resident killer whale (SRKW) forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this PA includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				aff ect, but is not likely to adversely affect, the SRKW species or designated critical habitat." This determination ignores the critically endangered status of the SRKWS, their reliance on dwindling Chinook salmon runs, and need for more food, especially the more nutritious and larger wild Chinook. SRKWs engage in crucial foraging in and around the mouth of the Columbia River in winter and spring, which are particularly key times for their health and reproductive success.	Columbia River in winter and spring (See BA Chapter 3.5). The CSS model results of the PA predicts Snake River Chinook salmon and steelhead would have relative improvements in Smolt-to-Adult return rates of 35 percent and 28 percent, respectively (see BA Chapter 3.5). The Smolt-to-Adult return rate (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adult. While recovery targets will require more than just the efforts of Federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The 2019 National Marine Fisheries Service (NMFS) Fisheries BiOp included increased spring spill operations that are similar to the operations proposed in the Draft EIS, and NMFS validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources. Appendix V of the Final EIS includes the NMFS and U.S. Fish and Wildlife Service (USFWS) Biological Opinions issued for the CRSO EIS, demonstrating ESA compliance.
3970	29	Shelley Silbert	Great Old Broads for Wilderness	NOAA lists the SRKWs as one of its nine "species in the spotlight," which it defines as "among the most at risk of extinction in the near fut ure."47 Furthermore, NOAA states that for species in the spotlight such as SRKWs "their populations are declining, and they are considered a recovery priority #1. A recovery priority #1 species is one whose extinction is almost certain in the immediate future because of rapid population decline or habitat destruction." Southern Resident Killer Whales are starving. This starvation causes them to metabolize stored fat, which releases toxins into their system, impacting their own health, and causing high rates of reproductive failures. Chinook salmon are over 80% of their diet, and they aren't getting enough to eat. Transient killer whales that are found in the same range as the SRKWs are healthy, enjoying great reproductive success and increasing their numbers because they have plenty of prey-seals and other marine mammal s.48	The co-lead agencies agree that the Southern Resident killer whales (SRKWs) are an icon of Pacific Northwest culture and an enduring legacy. As detailed in previous responses to comments from your organization, the co-lead agencies analyzed the effects of the CRSO Multiple Objective Alternatives, including the Preferred Alternative, in the FEIS and found that effects among the alternatives would vary from negligible (MO1, MO2, MO4, and Preferred Alternative) or minor beneficial effects (MO3). The Preferred Alternative has minor effects to SRKWs as described in Section 7.7.8. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Thus, the co-lead agencies expect salmon and steelhead increases would come from operational measures and existing hatchery production carried forward into the Preferred Alternative.
3970	30	Shelley Silbert	Great Old Broads for Wilderness	2. The Biological Assessment Fails to Accurately Assess the Proposed Action's Impacts on the Critically Endangered SRKWs Requiring a Recovery Priority #1. The BA contains several notable factual errors. One erroneous statement is that the SRKWs population is estimated at 73. (pg. 3-598). The BA's citation is from the Center for Whale Research (CWR) population data as of Sept. 6, 2019. However, well prior to the issuance of the DEIS on February 28, 2020, CWR reported on January 24, 2020 that L-41 Mega was missing from a sighting of his other family members and was presumed dead.49 Lynda Mapes of the Seattle Times reported on January 28, 2020, about the presumed death of L-41, bringing the population of Southern Resident areas to only 72, the lowest in 45 years. 50 His death was noted as particularly significant because "L41 was an important whale in the southern resident families. He and one other whale, JI, fathered most of the calves born to the pods since 1990." In this critically endangered SRKW population, the death of even one more member, especially a mature breeding male, is potentially devastating to further recovery. This key fact should have been reflected accurately in the BA, as their diminishing population is a crucial fact and compelling concern. At the time of their 2005 ESA listing, the SRKWs numbered 88. Fundamentally, an "endangered" listing means that the responsible agencies should be managing the species for recovery. In the SRKWs' case, the responsible federal agency, NOAA, established a recovery goal for down-listing of 2.3% increase annually, based on historic growth rates from 1984-1996 for the species. This 2.3%, recovery rate yields a projected increase of SRKWs at about 20+ per decade. Accordingly, based on NOAA's projections for recovery, there should be around 120 SRKWs by 2020. But instead of a healthy increase, the SRKWs have tragically decreased to just 72 now, with their prospects for recovery poor unless immediate, meaningful action is taken to save them. NOAA's recent findings recogni ze that the main obstacle to SRKW recovery is a severe shortage of their preferred food, Chinook sal mon.52	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not require the co-lead agencies to take affirmative actions to recover ESA listed species. The population dynamics of the SRKW are complicated and there are multiple factors that contribute to the overall success of this species. The quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differently from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for the whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall-run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall-run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. According to NMFS and the EPA, the estimated SRKW population has fluctuated between 67 and 98 whales between 1960 and 2015. The Snake River dams were constructed between 1962 and 1975. The SRKW population increased from a record low in 1970 to its highest population numbers in 1995. Those years were not high years for Snake or Columbia River Chinook Salmon. Ocean conditions between 2011 and 2013 were good years for salmon. At the same time, 2010 and 2013 were good outmigration years. Particularly, 2011 and 2012 were above normal in water supply, which would mean more cooler water was available and there was better survival of salmon, and 2011 through 2014 were higher than normal spill years as well. The combination of outmigration and ocean conditions created improved adult salmon returns. The EIS has analyzed spill as a measure in the Preferred Alternative and determined the overall effect to SRKW to be negligible in large part because hatchery production is consistent between the No Action Alternative and the Preferred Alternative. Because the impact from the Preferred Alternative was determined to be negligible, the agencies determined that existing hatchery production would be sufficient to address any potential impacts to prey availability for SRKWs. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent Congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as the Lower Snake River Compensation Plan (other than under MO3), which is administered by USFWS. The Preferred Alternative and Proposed Action in the agencies' biological assessment carry forward certain measures described in Chapters 2 and 7 of the EIS, which include continued salmon and steelhead hatchery production. The Preferred Alternative has negligible effects to SRKWs as described in Section 7.7.8. FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3..6.2.6 and Table 3-102). FEIS Chapter 7 (Preferred Alternative), has been updated with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon (Section 7.7.8). The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. Finally, the 2019 NMFS Fisheries BiOp included increased spring spill operations that are similar to operations evaluated in CRSO EIS, and NOAA validated that the hatchery production of Chinook salmon mitigates for the impacts of operating the Columbia River System and total mortality through the mainstem migratory corridor from all sources.
3970	32	Shelley Silbert	Great Old Broads for Wilderness	3. The BA Makes Misleading and Overly Broad Assertions about the SRK WS. The BA says that in the spring, summer , and fall, the SRKW are found in the inland waters of Puget Sound, the Northwest Straights [sic] and southern Georgia St rait ." [This area is commonly refer red to as the Salish Sea]. But this broad assertion ignores both the historical evidence that SRKWs range over half the year away from the Salish Sea, and recent patterns where they've been absent from the Salish Sea during summer mont hs, likely due to not enough prey being available. Both of these topics are described in more detail below. Historically, as noted in a recent scientific report by a group of distinguished kille r whale scientists, "Southern Resident Killer Whales & Columbia/Snake River Chinook: A Review of the Available Scientific Evidence, February 2020," 53 (hereafter "2020 SRKW Scientists Report "), the SRKWs' geographic range is not confined to the Salish Sea for over half the year : "The Southern "Resident" killer whales got their name because they used to be seen annually (i.e. " resident ") in the inland waters of the Salish Sea/Puget Sound during the late spring through early fall months. Even historically, however, this genetically distinct population of killer whales has spent more than half their time swimming back and forth throughout their known range as far south as Monterey, CA and as far north as Southeast Alaska. Their visits to the coastal waters off Westport, Washington and the mouth of the Columbia River coincide with high concentrations of spring Chinook salmon." Moreover, in the past few years, the SRKWs have not consistently been in their "resident areas" of the Salish Sea during the warmer months, but instead have been off the Pacific Coast. This pattern indicates that their foraging patterns are changing, likely due to the lack of Chinook salmon in the Salish Sea.	SRKW analysis has been described in the EIS, including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The SRKW analysis considered spring and fall Chinook within the Columbia River to be food sources for the SRKW. MO3 causes moderate increase to these two ESUs. This would cause a minor effect in SRKW food sources. The ocean factors are a major component of the condition and availability of the salmon to SRKW that needs further study. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). This conclusion is based on the fact that food available to Southern Resident killer whales from the lower Snake River comprises only a small percentage of their overall diet, however, it may be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Changes to this portion of the whales food availability on the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but will not change their overall condition or population dynamics. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). Additional details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect

Additional details on the most crucial Chinook salmon prey stocks for SRKW, as well as their population and range, are available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this National Marine Fisheries Service (NMFS) StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613.
3970	33	Shelley Silbert	Great Old Broads for Wilderness	4. The BA Discounts the Importance of Chinook Salmon Runs from the Columbia/Snake Basins to the SKRWs, Pointing Instead to Puget Sound and Fraser River Stocks. To a starving creature, every meal is important, and the Columbia/Snake runs are particularly so. The 2020 Scientists' Report provides a clear picture of the importance of Columbia/Snake River runs of Chinook salmon to the SRKWs: "The best available science indicates that the whales are likely to be especially reliant on the Columbia/Snake River watershed's early spring, nutrient-rich Chinook salmon runs. Indeed, the mouth of the Columbia Basin is one of the Southern Resident areas' favorite places to fish. Data compiled from tagged whales, dedicated surveys, and passive acoustic monitoring indicates the Southern Residents spend significant time in the winter and spring off the mouth of the Columbia and have been present there thirty-five times more often than would be expected by chance. Analysis of fish scale and Southern Resident fecal samples collected on the outer coast indicate that, as is the case in inland waters of the Salish Sea/Puget Sound, Chinook are the primary species consumed on the outer coast and that over half the Chinook consumed by the Southern Residents are from the Columbia River Basin.... In partnership with the Washington Department of Fish and Wildlife (WDFW), NOAA created a preliminary priority list of West Coast Chinook salmon stocks important to the Southern Resident areas' recovery. Of the top fifteen priority stocks, seven are from the Columbia Basin, including both fall and spring Chinook" 56 The link between the depleted Chinook salmon runs in the Columbia/Snake system and the depleted status of the SRKWs is clear. "The current depleted level of adult Chinook returns to the Columbia is a critical component of the prey scarcity these whales face . This shortage is compounded by the fact that adult Chinook returns, especially hatchery stocks t hat comprise most of these returns, consist of an increasing number of younger - and hence smaller - fish than in the past . This fact means that these whales must expend far more energy today to obtain the same caloric value of prey with the net effect of less nourishment. The claim that maintaining the continued low adult salmon returns to the Columbia does not harm these critically endangered whales is not scientifically supported"	SRKW analysis has been described in the EIS, including in the FEIS Chapter 3 (Vegetation, Wetlands, Wildlife, and Floodplains) has been updated for SRKW (Section 3.6.2.6 and Table 3-102) and FEIS Chapter 7 (Preferred Alternative) with additional analysis information on SRKW and potential increase in forage fish, in particular, Chinook salmon in Section 7.7.8. The co-lead agencies utilized current high quality information and best available science in its analysis of the effects of the operation, maintenance, and configuration of the CRS projects. The SRKW analysis considered spring and fall Chinook within the Columbia River to be food sources for the SRKW. MO3 causes moderate increase to these two ESUs. This would cause a minor effect in SRKW food sources. The ocean factors are a major component of the condition and availability of the salmon to SRKW that needs further study. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). This conclusion is based on the fact that food available to Southern Resident killer whales from the lower Snake River comprises only a small percentage of their overall diet, however, it may be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). Changes to this portion of the whales food availability on the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but will not change their overall condition or population dynamics. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). Additional details on the most crucial prey stocks for Southern Resident killer whales, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this NMFS StoryMap on Southern Resident killer whales: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS. The Biological Assessment (BA) describes the effect of the Proposed Action on the SRKW forage species (see BA Section 3.5.1.2, Southern Resident Killer Whale). The proposed changes in operation of the Columbia River System include increased spring spill during the downstream migration of juvenile spring and summer run Chinook salmon. The result of this action includes potential increases of juvenile fish passing through the spillways, reductions in juvenile fish direct and indirect mortality associated with downstream passage, and the Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW.
3970	34	Shelley Silbert	Great Old Broads for Wilderness	5. CRSO-DEI S Co- agencies Use of Old Data, Speculati on and Optimism Fails to Ensure Snake River Basin Salm on and So uthern Resid e nt Orea Survival and Recovery. The CRSO-DEIS BA is relying on an outdated 2008 determination that found that the Columbia River system management was based on expected status improvements for prey originat ing from the Columbia as a result of three key fact ors: (1) previous modifications to system operations and configuration to benefit salmonids; (2) ongoing artificial production programs in the Columbia River Basis; and (3) implementation of the 2008 BiOp ' s RPA actions, with further improvements to mainstem migration conditions, spawning and rearing habitat, predator manage ment, and hatchery reforms. This determination was speculative in 2008 , and with the benefit of hindsight, far too optimistic. The 2008 "expected status improvements" are not working for salmon or SRI<Ws, as shown by the alarming decr ease in populations of these species. Moreover, as pointed out in the 2020 SRI<W Scientists' Report, hatchery fish are inferior to wild salmon to fulfill the SRI<Ws' nutritional needs.	The co-lead agencies disagree with the commenter's characterization of the Biological Assessment (BA). The BA provides context associated with the 2008 Biological Opinion (BiOp), the supplemental 2014 BiOp, and 2019 BiOp and in all three BiOps, National Marine Services Fisheries (NMFS) analyzed the total mortality of Chinook salmon associated with the Columbia River System and concluded that improvements to the status of ESA-listed Chinook salmon stocks in the long-term, based on the reasons highlighted in this comment (e.g., modifications to system operations and configurations to benefit anadromous fish passage, upstream and downstream, coupled with artificial production and hatchery reform, with continued on-going mitigation, avian, fish and pinniped predator management, and tributary and habitat improvements), were not likely to adversely affect Southern Resident killer whale (SRKW). Comparative Survival Study (CSS) model predicts increases in numbers of returning adults, which will benefit SRKWs foraging in and around the mouth of the Columbia River in winter and spring (See EIS Section 7.7.8). The CSS model results predicts Snake River Chinook salmon would have relative improvements in smolt-to-adult returns of 35 percent (see EIS Section 7.7.4). The smolt-to-adult return ratio (SAR) is the rate at which of a group of fish survive from their smolt life stage to a defined ending point where they return as adults. While recovery targets will require more than just the efforts of federal agencies, the CSS models indicate the potential for SARs of Snake River Chinook salmon and steelhead to increase to levels that could approach recovery targets set by the Northwest Power and Conservation Council. The BA, also consistent with the EIS, acknowledges past improvements to the configuration and operation of the Columbia River System, additional improvements to the environmental baseline as a result of completed estuary and tributary habitat actions, and the prospective non-operational conservation measures proposed in Chapter 2 of the Draft EIS, all contribute towards maintaining and improving Chinook abundance. Relevant conservation measures include, among other things, a commitment to continue funding the conservation and safety net hatchery programs listed in Chapter 2 of the Draft EIS. As discussed above, the agencies will fulfill congressionally authorized hatchery mitigation objectives through the funding of hatchery programs that are operated consistent with their independent hatchery program consultations during the term covered by this consultation. Based on those hatchery program consultations, the production levels associated with congressionally authorized hatchery mitigation objectives will continue, at minimum, to be consistent with levels previously analyzed by NOAA in the system consultations in 2008, 2014, and 2019. For the 2020 ESA consultations, therefore, the agencies expect that collectively, all of the actions described above (substantial modifications to migration conditions designed to benefit key prey species, combined with improvements to Chinook spawning and rearing habitat in the tributaries and Columbia River estuary, and continued hatchery production) ensure that remaining Chinook mortality from all sources in the mainstem migratory corridor will continue to be more than offset, resulting in a net gain in Chinook salmon abundance available as a prey source for SRKW. The co-lead agencies note that, consistent with previous responses to comments from your organization, the referenced scientists report (Southern Resident Killer Whales & Columbia/Snake River Chinook: A Review of the Available Scientific Evidence, February 2020), had not been released at the time of writing the Draft EIS. The co-lead agencies have since considered the February 2020 referenced paper and have found that this paper does not change the analysis conducted for the CRSO EIS.
3970	35	Shelley Silbert	Great Old Broads for Wilderness	Conclusion Regarding Southern Resident Orea Survival Breaching the four Lower Snake River Dams (LSR Ds), according to the CSS modeling, would result in an estimated four times increase in the return of Chinook salmon within a few years. Consequently, independent SRI<W scientists have concluded that breaching the four LSRDs is the best, and likely only, way to recover SRI<Ws. "When all of this evidence is taken into account, we believe that , as a matter of scientific evidence, it is clear that lower Snake River restoration, including dam removal, is the single biggest and most effective step we can take to restore these two important species. The evidence of continued decline for both areas and Snake River Chinook also highlights the great urgency to take this action as soon as possible." Accordingly, the Co-agencies should revise the BA to determine that the Preferred Alternative will adversely affect the SRI<Ws, and instead implement a combination of LSRD breaching under MO3, plus 1 25% TOG spill at the 4 lower Columbia dams under MO4. This is the best and likely only ecological option that offers a near -term , meaningful route to recover this critically endangered species.	The Preferred Alternative (PA) from the CRSO Draft EIS forms the basis for the proposed action described in the Biological Assessment (BA). The co-lead agencies do not plan to update the content of the BA, but will continue coordinating with National Marine Fisheries Service (NMFS) and U.S. Fish and Wildlife Service (USFWS) to clarify content of this BA as needed (see Appendix V of Final EIS). If the clarifications affect the PA, the co-lead agencies will include those changes in the Final EIS. The EIS analysis found only a negligible to a minor effect to the Southern Resident killer whale (SRKW) would result from implementing MO3, which includes the measure to breach the four lower Snake River dams. This conclusion is based on the fact that Chinook available to SRKW from the lower Snake River comprises only a small percentage of their overall diet. Changes to this portion of the whales food availability of the magnitudes predicted for MO3 may change the whales foraging behavior patterns slightly, but would not change their overall condition or population dynamics. Under the Draft EIS PA, hatchery origin Chinook salmon contribute to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by the U.S. Fish and Wildlife Service (USFWS). With respect to the request to consider a combination of MO3 and Multiple Objective alternative 4 (MO4), which includes the measure to spill at the lower Columbia River dams of 125% total dissolved gas (TDG) levels, the co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the Endangered Species Act (ESA), the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					The agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these Multiple Objective alternatives (MOs) were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire United States by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
3970	36	Shelley Silbert	Great Old Broads for Wilderness	Balancing "Uses" Against "Resources,'1 aka "Natural Resources" As pointed out in the 2020 CRSO-DEIS Executive Summary, the Opinion and Order from the U.S. District Court for the District of Oregon 59 states that the EIS should evaluate how to ensure that the prospective management of the CRS is not likely to jeopardize the continued existence of any endangered or threatened species, or result in the destruction or adverse modification of designated critical habitat. Regarding operation of hydroelectric dams on the Columbia and Snake Rivers, in its 2000 Biological Opinion, NOAA Fisheries concluded, "breaching the four lower Snake River dams would provide more certainty of long-term survival and recovery [of salmon and steelhead] than would other measures ." Yet, beyond the status quo, the overall approach of the agencies in preparing the 2020 CRSO DEIS diffuses any focus on ensuring species survival, while instead belaboring complexity and a need for balancing uses. In doing so, the CRSO-DEIS functions as a diversion from the Court's mandate and fails to meet the expectations of the Court Order. The CRSO-DEIS's Preferred Alternative (PA) dismisses the scientifically soundest means of ensuring the continued existence of the Snake River Basin's endangered and threatened species -breaching of the 4 lower Snake River dams. About Alternative 3 (M03), including breaching, the CRSO-DEIS Executive Summary (ES) (page 24) states that M03 "predicts the highest benefit for several of the ESA -list ed juvenile and adult salmon." In light of Snake River salmon species' slide toward extinction, that statement alone satisfies the court mandate and leads to an obvious conclusion: M03 ought to be the "preferred alt ernat ive ." Yet, in denying M03 "preferred" status, the Executive Summary (p.29) notes, "...this alternative was not identified as the Preferred Alternative due to the adverse impacts to other resources such as transportation, power reliability and affordability, and greenhouse gas emissions." Today, calling transportation, power reliability and affordability, and greenhouse gas emissions "resources" amounts to basing CRSO-DEIS conclusions on a misnamed and nearly empty box. Let's first understand first that these are not "resources." Transportation and power production are uses of resources, and greenhouse gas emissions are a societal problem, not a resource. Resources related to the DEIS are water, habitat and fish. The court order mandates a protective focus, in decision-making, upon these " resources." Removal of the 4 lower Snake dams, plus a TDG of 125% sat urat ion at the tailraces of the 4 lower Columbia dams, preceded by an interim 125% TDG at all 8 dams, would be the best -action toward that focus. Further, that action would allow the co-agencies to meet their "Major Conclusion" of meeting "the congressionally authorized purposes of the system (ES, p.35), since all remaining hydropower dams in "the system" would remain intact, functional, and able to meet the Pacific Northwest's energy demand.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. The co-lead agencies are required to evaluate a reasonable range of alternatives in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. The National Environmental Policy Act (NEPA) and the ESA establish different standards for legal compliance and have different approaches to the analysis of the effects of the action. Because of these differences, the analyses performed in the Draft EIS and in the Biological Assessment (BA) are tailored to the requirements of each regulatory process. While the EIS analyzes effects of the alternatives on all resources, and compares these and the Preferred Alternative to the No Action Alternative, the BA examines the effects of the proposed action, consistent with the Preferred Alternative, on ESA-listed species and designated critical habitat. Under the ESA, the action agencies must develop an analysis of the effects of the action sufficient to allow the USFWS and NMFS to determine whether the action will jeopardize the continued existence of an ESA-listed species or destroy or adversely modify designated critical habitat. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as MO3, which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives including those for: resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 which includes breaching the four lower Snake River dams because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The co-lead agencies disagree, however, that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative. For Power and Transmission, MO3 and MO4, individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. This potential alternative has not been evaluated for direct, indirect and cumulative effects to other resources. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
3970	37	Shelley Silbert	Great Old Broads for Wilderness	1. CRSO-DEIS Preferred Alternative Considerations of "Use" Values Do Not Economically, Socially, Legally, or Environmentally Justify Salmon and Steelhead Extinctions. As detailed within this comment document, the CRSO-DEIS arguments against Alternative 3 (MO3), particularly its arguments related to transportation and power reliability, are very weak, and growing weaker by the year. Further, suggestions that choosing MO3 would necessarily and irresolvably increase greenhouse gas emissions is at best flimsy. The Executive Summary (page 24) states, "...breaching the dams would not allow the co-lead agencies to operate and maintain the dams for their congressionally authorized, not mandated, purposes of navigation, hydropower, envisioned recreational benefits, and water supply for irrigation purposes." Speaking of balance, we suggest first that the co-agencies "envision" free flowing river recreational benefits equal to or surpassing reservoir recreation benefits, and also the social and economic effects of river recreation benefits. Second, we suggest that you jar yourselves out of the time period when the co-lead agencies were first congressionally authorized - not mandated - to operate and maintain the dams and lift yourselves into the present day- a much less positive-looking day for lower Snake River navigation and hydropower and a devastating day for salmon ... and, in turn, for Southern Resident areas. The CRSO-DEIS promotes improving the same or similar fish passage conditions that, in 2020, the agencies, the public and our policymakers clearly know have failed. Just visit nearly fish-less natal streams during spawning season, drop a line into the Clearwater River to catch no fish, or read local/regional newspaper coverage, such as Lewiston Tribune coverage of the salmon/steelhead decline issue and its painful effects on local people and communities. The agencies have asked the public and our policymakers to dismiss the scientifically validated soundest solution and to ignore a visible upriver scarcity of salmon, in favor of sustaining waning values, such as lower Snake waterway freight transportation, and an aging, unjustifiably costly, no longer essential lower Snake hydropower system. The agencies speak of "water supply" as if a free-flowing river is not itself a source of water - reservoir not required.	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the Multiple Objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The Preferred Alternative (PA) for long-term system operations, maintenance and configuration of the CRS presented in the Draft EIS is based on todays conditions and environment. Technology is quickly changing, as is the regions dynamic environment and energy market, and the region needs to consider new information and adaptively manage resources. The co-lead agencies recognize that no matter which alternative in the CRSO EIS is identified as the PA, the identification would likely draw criticism from some stakeholders or sovereigns. The region includes stakeholders, sovereigns, and other interested parties with diverse and varied opinions on these very important topics, and many are strong in the belief that their perspective is the best path forward. Factors, both human-caused and natural, that are outside the responsibility and control of the co-lead Federal agencies also contribute to the decline and recovery of fish, and would continue to strongly influence fish and their habitat. Salmon and steelhead have been adversely affected in the Columbia River Basin over the last century by many activities including human population growth, urbanization, introduction of exotic species, overfishing, development of cities and other land uses in the floodplains, water diversions for all purposes, dams, mining, farming, ranching, logging, hatchery production, predation, ocean conditions, and loss of habitat. Operation, configuration and maintenance of the CRS requires mitigation for its effects, and the EIS is not intended or required to serve as an overall salmon recovery plan for the region. All of the human-caused impacts that have contributed to the decline of fish, and how the region should properly and effectively address those impacts, should be part of the continued regional discussion. The co-lead agencies look forward to participating in that discussion. For hydropower, the average annual value of the four lower Snake River dams exceeds the average annual equivalent costs. The generation value at the four lower Snake River dams can be described by a range between the cost to replace the generation through new conventional resources or through a portfolio of zero-carbon resources. Although the costs of replacing the power with market purchases was analyzed, it is unlikely that short-term wholesale power markets could reliably replace the power for the long-term. This range would put the annual value of power between $240 million and $500 million for the four dams combined. These numbers represent about 90 percent of the lost benefits cited in Table 3-171 of the Draft EIS because the four dams represent about 1,000 aMW of the 1,100 aMW of lost generation estimated in MO3. The average annual cost to operate and maintain all authorized purposes at the four lower Snake River dams is $75 million (Appendix Q, Table 5-1) and the annual-equivalent capital costs are $32 million (Appendix Q, Table 4-1). Hydropower costs funded by Bonneville represent about $50 million of the total annual operations and maintenance costs and nearly all of the annual capital costs, approximately $31 million. This puts the annual-equivalent power-specific costs at approximately $81 million a year. As a result, the net benefits from hydropower for the four lower Snake River dams are between $159 million and $419 million and the benefit-cost ratios are between 3.0 and 6.2. If the $34 million per year for the Lower Snake River Compensation Plan is added to the capital and expense costs, benefits still exceed costs under each replacement power scenario. Considering these costs, the net benefits range from $125 million to $385 million and the benefit-cost ratios range from 2.1 to 4.3. In the less-likely scenario that generation could be reliably replaced with short-term wholesale market purchases and assuming that the four dams represent 90% of the $150 million in market purchases required to replace the lost generation cited in MO3 (see Table 3-170), the lower bound for net benefits would fall to $54 million and the benefit-cost ratio would fall to 1.7. With the Lower Snake River Compensation Plan included, the lower bound for annual net benefits becomes $20 million and the benefit-cost ratio becomes 1.2. From a resource competitiveness perspective, the four lower Snake River dams are among the least costly generating resources in the Federal Columbia River Power System (FCRPS) and the planned investment strategy is expected to maintain that status. As shown in the Federal Hydropower presentation at the 2018 Integrated Program Review1/, the Headwater/Lower Snake Asset Class/2 is forecast to have a 50-year levelized cost of generation/3 of $11.41/MWh based on the direct funded capital and expense (O&M) programs outlined in that process. These costs remain competitive with volatile Mid-Columbia spot market energy prices, which averaged $37/MWh in 2019 and have averaged $21/MWh in 2020.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					1/ The Integrated Program Review (IPR) allows interested parties to see and comment on all relevant FCRPS O&M spending level estimates in the same forum. The IPR occurs every two years, or just prior to each rate case, and is the public review for the costs that will be recovered through rates the following two-year rate period. Long-term forecasts for the next 50 years and major upcoming projects are also shared in this forum. This information is available here: https://www.bpa.gov/Finance/FinancialPublicProcesses/IPR/2018IPR/IPR%202018%20Fed%20Hydro%20Workshop.pdf and is incorporated by reference into this EIS. 2/ In the 2018 Integrated Program Review, the Headwater/Lower Snake Asset Class consisted of the four lower Snake River dams, Hungry Horse, Libby, and Dworshak dams. These projects were grouped together because they have similar cost characteristics. The Levelized Cost of Generation for the four lower Snake projects alone is slightly lower than that for the whole class including the headwater projects shown in the table. 3/ Levelized Cost of Generation is defined as the forecast direct costs and administrative overhead of producing power at a plant annualized over a 50-year period. This cost includes direct funded operations, maintenance, administrative and capital costs as well as Columbia River Fish Mitigation (CRFM) costs. Bonneville systemwide mitigation costs, such as its Fish and Wildlife program, are not included in this metric.
3970	38	Shelley Silbert	Great Old Broads for Wilderness	2. The CRSO-DEIS's Weighing of "Social Welfare" Costs is Imbalanced and Incomplete. To develop the PA, "the co-lead agencies selected a combination of suites of measures.'..based on how well the measures met the Purpose and Need Statement and EIS objectives, with consideration of environmental, economic and social effects." (ES, p..32} Yet, the co-agencies ask the public to favor, even sanction, the needs of fewer than two dozen irrigators all located on just one of the four reservoirs, the Ice Harbor Reservoir. The Executive Summary (p. 28} "assumes," were the dams breached, that 47,926 acres would no longer be irrigated at a social welfare cost of $458 million." That assumption is false on the face of it, since the river itself would remain available for irrigation. A one-time expense of aid to farmers to upgrade pumps and lengthen water lines could ensure sections of the 47,926 acres could be irrigated post breac hing. At the same time that it expresses concern for irrigators, the CRSO-DEIS circles widely around and/or disregards the needs of Oregon, Washington and north central Idaho fishing-related communities, which right now are suffering a severe "social welfare" cost due to the loss of thriving salmon and steelhead run s. The CRSO-DEIS disregards the individuals and businesses (largely small businesses) that create jobs in those communities and the significant positive impact of fishing on the overall economies of Washington, Oregon and Idaho. Sport fishing in Idaho generates hundreds of millions of dollars of spending every year, bringing much needed dollars to rural areas while adding millions in tax revenue to state co ff ers. Sport fishing in the state is a tremendous economic engine..." - IDFG 2001 Survey: Fishing Has Major Impact on Idaho Economy In 2019, the Idaho Department of Labor's economist for Region 2 (north central Idaho) reported that salmon and steelhead fishing cont ribut e an estimated $8.61 million per month to the region. That significant, indeed vit al, economic impact by far exceeds the $2-$3 million per year Port of Clarkston, Washington's Manager Wanda Keefer estimates is the impact of her port ' s cruise ship traffic on her community. The cruise ship passengers, incidentally, buy their trips from non local cruise ship companies; ar e dined, wined and lodged on-board; and passe ngers' tips go mostly to non-local cruise ship staff. It is not difficult to assume that, were t ourist cruise ships no longer able to use the Port of Clarkston due to lower Snake dam breaching, very few businesses in the Clarkston community would suffer. None would close. However, with the ongoing dramatic decline (and likely extinction) of salmon and steelhead runs, in the three states' rural fishing-relate d commun ities, nearly every business is negatively impacted, dropping some into suspension or closure, and even drawing a few whole communities to the brink of economic collapse. The CRSO-DEIS, however, fails to emphasize these fish-decline economic or social welfare imp act s. In fact, while analyzing the economic impacts of each alternative - including water supply, irrigat ion, nav igat io n, and hydropower impact s, the co-agencies ignored the sports fishing economy and its estimated $2 billion region-wide economic contribution. The co agencies neglected to use publicly available data sources that quantify the devastating economic impacts of declining salmon and steelhead population to the Northwest's rural communit ies. In 2005, Don C. Reading, Ph.D., presented the results of a study titled "The Potential Economic Impact of Restored Salmon and Steelhead Fishing in Idaho." Reading concluded, "The recovery of Snake River Basin salmon and steelhead runs would provide a truly renewable resource that brings substantial economic benefit to Idaho." The study states that a restored salmon and steelhead fishery could reap annual direct and indirect economic benefits of $544 million . In today's dollars, that level of impact would exceed an annual $700 million.63	While the EIS does evaluate and find that potential impacts to irrigators may occur under MO3, EIS also provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the alternatives, including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). Effects of the Preferred Alternative can be found in Chapter 7. The recreation analysis for the EIS considered the broad range of recreational activities supported by the region, including recreational fishing. While the analysis described any potential impacts to recreational fishing visitation, the EIS did not estimate these impacts separately from the overall impacts to recreation, or estimate changes in fishing visitation related to changes in fish abundance. The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. The social welfare values and regional economic effects associated with recreational fishing under the action alternatives as well as river recreation post dam breach under MO3 were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. . Cruise ship visitation is characterized in Section 3.10 Navigation. Section 3.10.3.5 describes the contribution of cruise ships as providing demand for approximately 230 jobs in the region, which would include employment in the industry itself as well as increased demand for services at ports of call. The EIS does not claim that business closures would result from changes in the navigation channel access under MO3.
3970	39	Shelley Silbert	Great Old Broads for Wilderness	3. As Has Been the Multi-decade Pattern of the Co-agencies, the CRSO-DEIS's "Temporal Scope" a) Neglects the fact that Snake River Salmon and Steelhead Populations Have Been Severely Affected by the Lower Snake Dams So That Today the Extinction of the ESA Listed Salmon and Steelhead Looms Close in Time, and b) Ignores the Law. In view of the above dollar figures, keep in mind, too, that over the last thirty or so years, taxpayers and electricity ratepayers have spent a well-publicize d $16.8 billion attempting to recover thirteen threatened or endangered salmon and steelhead in the Columbia River Basin. None of the thirteen is on a path to recovery . In view of the above span of thirty years of failed effort, consider that in the CRSO-DEIS Executive Summary," (p.8) the agencies state that the "temporal scope of the EIS is assumed to be 25 years from the signing of the records of decision (RODs)... However, the socioeconomic analysis uses a 50-year period [which]... provides a long-term perspective that enables the co lead agencies to distinguish between short-term socioeconomic impacts that may occur during the implementation of alternatives and long-term effects that would occur after implementation is completed." Such a temporal span of 25-50 years is, as noted above, known by the river-using public, the newspaper-reading public, and by scientists and policymakers to be a scope that will ensure not salmon and steelhead recovery, but their extinction. We suspect the CRSO-DEIS co-agencies also know. Without designating Alternative 3 (MO3), breaching, as the preferred alternative, the DIES does nothing more than foretell and facilitate a natural resource tragedy. Documentation of the above characterization exists in three decades of court opinions that have rejected dam management plans for their failure to be science- base d, law-based, or genuine in their intent ions. For example (emphases added): In his 1993 court decision, Judge F. Marsh wrote: "NM FS {National Mar ine Fisheries Service} has clearly made an effort ... But the process is seriously, 'significantly,' flawed because it is too heavily geared towards the status quo that has allowed all forms of river activity to proceed in a deficit situation - that is, relatively small steps, minor improvements and adjustments when the situation literally cries out for a major overhaul. Instead of looking for what can be done to protect the species from jeopardy, NMFS and the action agencies have narrowly focused their attention on what the establishment is capable of handling with minimal disruption." In 2000, Judge Redden ruled that the 2000 BiOp was "arbitrary and capricious because it relied on 1) federal mitigation actions that were not subject to the consultation process that is required under the Endangered Species Act and 2) non-federal mitigation actions that were not shown to be reasonably certain to occur." The judge ordered a new BiOp be written by 2004. 64 By 2004, more populations of Columbia and Snake River salmon and steelhead had become listed as endangered or threatened, and Judge Redden rejected the federal government's 2004 BiOp. In 2005 - "The government's inaction appears to some parties to be a strategy intended to avoid making hard choices and offending those who favor the status quo. Without real action from the Action Agencies, the result will be the loss of the wild sal mon." 66 The 2008 BiOp was also rejected. - "Under this approach, a listed species could be gradually destroyed, so long as each step on the path to destruction is sufficiently modest. This type of slow slide into oblivion is one of the very ills the ESA [Endangered Species Act] seeks to prevent ." In 2011- "The history of the Federal Defendants' lack of, or at best, marginal compliance with the procedural and substantive requirements of the ESA [Endangered Species Act] ... has been laid out in prior Opinions and Orders in this case and is repeated here only where relevant. The court went on to call the federal defendants' plan "neither a reasonable, nor a prudent, course of action." In his 2011 decision, Judge Redden also wrote: "Instead of following this court's instructions, NOAA Fisheries abandoned the 2000 BiOp and altered its analytical framework to avoid the need for any ...reasonable and prudent alternatives. As the parties are well aware, the resulting BiOp was a cynical and transparent attempt to avoid responsibility for the decline of listed Columbia and Snake River salmon and steelhead there is ample evidence in the record that indicates that the operation of the FCRPS causes substantial harm to listed salmonids NOAA Fisheries acknowledges that the existence and operation of the dams accounts for most of the mortality of juveniles migrating through the FCRPS. As in the past, I find that irreparable harm will result to listed species as a result of the operation of the FCRPS." Judge Redden ordered a new biological opinion by 2014. In 2014, "the Court ruled that federal action agencies adopting a record of decision implementing a biological opinion must prepare an environmental impact statement when the relevant provisions of the National Environmental Policy Act have been triggered that the federal action agencies {here, the Corps, BPA and BOR) prepare a comprehensive environmental impact statement that evaluates a broad range of alternatives that may finally break the decades-long cycle of court-invalidated biological opinions that identify essentially the same narrow approach to the critical task of saving these dangerously imperiled species. The federal consulting and action agencies must do what Congress has directed them to do." In 2016 - Judge Simon wrote, "The Ninth Circuit has already cautioned that the Endangered Species Act prohibits any federal agency action from allowing a species to have a 'slow slide into oblivion' and that agency action may not 'tip a species from a state of precarious survival into a state of likely extinction.' " Yet that "slow slide" is exactly what the government agencies have set in motion, so that today the salmonids are indeed in a state of critical precariousness. NOAA Fisheries' Consultation Handbook recognizes that 'the longer a species remains at low population levels, the greater the probability of extinction from chance events, inbreeding depression, or additional environmental disturbance." We are inclined to believe NOAA Fisheries should have added, ...or the probability of extinction from a deceptive lack of meaningful action by federal agencies. Throughout these 3 decades the agencies seem hellbent on not only driving Snake River salmonids into extinction, but in the process to also drive the Endangered Species Act into nonexistence. And yes, we believe the 2020 DEIS co-agencies have set out to render the ESA powerless, simply by ignoring it. Today, with respect to the above mentioned "additional environmental disturbance," global warming rises to the top. In 2015, as widely known, Snake Basin fish	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the CRS. Recovery of ESA species is the purview of National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. This EIS has been developed in consultation with National Marine Fisheries Service and U.S. Fish and Wildlife Service to find an acceptable balance that allows the co-leads to meet the stated Purpose and Needs Statement while minimizing impacts to affected ESA species and their habitats. The co-lead agencies are required to evaluate a reasonable range of alternatives in the EIS. Alternatives for this EIS were developed from measures identified during public scoping, regional forums with scientists and technical experts from cooperating agencies, and expert opinion from within the co-lead agencies and in the literature. These alternatives represent a reasonable range of alternatives for the maintenance and operation of the CRS. The EIS set forth eight objectives which, in tandem with the Purpose and Need Statement, establish the framework for evaluating the ability of an alternative to satisfy the co-lead agencies numerous legal obligations. The Preferred Alternative is predicted to benefit ESA-listed juvenile and adult anadromous salmonids (two of the objectives), but not as much as Multiple Objective 3 (MO3) which includes breaching the four lower Snake River dams. The Preferred Alternative also meets the EIS objectives for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. MO3, by contrast, has significant regional economic and community effects, and meets fewer of the EIS objectives. Thus, in the Draft EIS the co-lead agencies did not identify MO3 because the Preferred Alternative is more likely to satisfy multiple complex and at times conflicting legal requirements for a complex system. The EIS concluded MO3, which includes breaching the four lower Snake River dams would have greater improvement to certain salmon species in the lower Snake River. It did not, however, conclude there was greater certainty of that result in MO3 over any other alternative. Because of delayed response time in MO3, and the potential severity of the short term effects, MO3 would likely have the most substantial uncertainty in terms of beneficial effects. Section 3.5 provides a summary of the fish analysis for the No Action Alternative and four of the multiple objective alternatives. Chapter 7 provides a summary of the fish analysis for the Preferred Alternative. With respect to the Preferred Alternative, the CSS model predicts that average Smolt to Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The NMFS COMPASS and Life Cycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information. Based on the EIS analysis of the Preferred Alternative, it will make a substantial contribution towards recovery targets. NEPA and the ESA establish different standards for legal compliance and have different approaches to the analysis of the effects of any action. Because of these differences, the analyses performed in the Draft EIS and in the Biological Assessment (BA) are tailored to the requirements of each regulatory process. While the EIS analyzes effects of the alternatives on all resources, and compares these and the Preferred Alternative to the No Action Alternative, the BA examines the effects of the proposed action, consistent with the Preferred Alternative, on ESA-listed species and designated critical habitat. Under the ESA, the Action Agencies must develop an analysis of the effects of the action sufficient to allow the USFWS and NMFS to determine whether the action will jeopardize the continued existence of an ESA-listed species or destroy or adversely modify designated critical habitat. The temporal scope of the EIS is assumed to be 25 years from the signing of the Record of Decision (ROD) in order to have a similar period of analysis for comparison of effects across resources for all multiple objective alternatives (with the exception of the socioeconomic-related resource analysis - 50 years). Regarding hydropower generation, conventional nuclear power units, as described in the comment, are not considered viable by the Council given various risks. The Council considers small modular nuclear reactors potentially viable as they address many of the risks identified with larger conventional nuclear units as described in the 7th Power Plan. For MO3, the EIS did consider small modular nuclear reactors (SMR) as a potential replacement for some of the attributes of the four lower Snake River dams and costs estimates were provided. See Draft EIS Section 3.7.3.5, Small Nuclear Reactor on page 3-909. However, as noted in the Draft EIS, the ramping capability of SMR is unknown. Thus it is unknown if a SMR would be able to provide ramping capability similar to the lower Snake River projects at this time. See Draft EIS on page 3-910. Appendix H provides further discussion on the selection of replacement power resources. The draft EIS also describes the operational characteristics of the four lower Snake River dams in Section 3.7.3.5, Lower Snake River Full Replacement (Used in Rate Sensitivity Analysis). As described in that section, although the dams are run-of-river, there is upstream storage that is used to increase their firm capacity, and they provide up to 2000 MW of sustained peaking capacity at certain times of the year. They also have unparalleled ramping capability the ability to quickly generate energy to match spikes in energy usage with over 2,000 to approximately 2,300 MW of capability in certain months of the year (see Table 3-160 in the draft EIS). The ramping capability is valuable for system balancing, which is used to serve load (consumed energy by houses, business, industry) and to balance out the variability that renewable generation causes to the system, such as when the wind does not blow or the sun is blocked by clouds. Finally, The comments suggestion that approximately $17 billion in fish and wildlife mitigation investment has been ineffective to recover ESA listed species is misplaced. Those investments delivered the intended results when considered in the appropriate statutory context of the Northwest Power Acts anadromous fish provisions which call for improved survival of such fish at FCRPS projects and sufficient flows between the projects to improve production, migration, and survival. For example, as of 2014 this investment had facilitated juvenile dam passage survival of 96% and 93% for spring and summer migrants respectively, see Endangered Species Act Federal Columbia River Power System 2016 Comprehensive Evaluation Section 1, at 17, t.2 (Jan. 2017), a marked improvement compared to when Congress passed the Northwest Power Act and the estimated average juvenile mortality at each mainstem dam and reservoir complex was 15-20% with losses recorded as high as 30%. See Nw. Res. Info. Ctr. v. Nw. Power Planning Council, 35 F.3d 1371, 1374 (9th Cir. 1994) (citing a Sept. 4, 1979 report by U.S. General Accounting Office describing the systems impacts on anadromous fish).

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				suffered severely from reservoir temperatures exceeding 68Q, and at times and in some locations, such as reservoirs and the mouths of tributaries that ordinarily would provide refuge, water temperatures reached a lethal-for-salmon 72 degrees. Warm water temperatures, especially since 2015, have continued to threaten fish survival, and that trend is, of course, predicted by scientists worldwide to continue. In a January 2020 "climate emergency" warning, 11,000 scientists in 153 countries said, "The climate crisis has arrived and is accelerating faster than most scientists expected." On October 27, 2015, eight former fish biologists and government fisheries department officials sent a letter to Will Stelle, Regional Administrator, West Coast Region, of the National Marine Fisheries Service (NOAA) regarding NOAA's climate change research and lack of application of that research to significant losses of Columbia and Snake Basin anadromous fish that occur (as in 2015} due to warm water temperatures. The letter speaks of NOAA's "unfortunate failure to take aggressive and necessary steps to address the effects of climate change on the freshwater habitat of threatened and endangered salmon and steelhead in the Columbia River Basi n. This failure is not new; it has accumulated over nearly two decades of inadequate and ineffective action. ... If the dead salmon up and down these rivers this summer [2015] did nothing else, they gave us a clear and unmistakable warning that continued reliance on the kinds of small steps and minimalist measures we have taken since Snake Ri ver sockeye were first listed under the Endangered Species Act over twenty years ago will not work." The temperature issue related to anadromous fish survival in the Columbia and Snake River basins is of such great import that on December 20, 2019, a 9th Circuit Court of Appeals panel ruled that the Environmental Protection Agency had failed to develop temperature limits [Total Maximum Daily Load (TMDL] required under the Clean Water Act. "Rising temperatures caused by dams that stagnate water flows, as well as discharges and climate change, are deadly to migrating fish like sa lmon . Anything above 68 degrees Fahrenheit makes it nearly impossible for fish to migrate upstream to spaw n." 73 The EPA petitioned for a rehearing of the case, but on March 30, 2020, a federal appeals court denied the EPA's petit ion. Clearly, for the past twenty-seven years, the agencies have been stuck on 'repeat.' The 2020 Preferred Alternative's phrase "additional combinat ion of measures" has exhausted itself. It's time the CRSO-DEIS co-agencies explain their malfeasance - to the public, the policymakers, and to the court. The agencies' stagnant approach to saving Snake River salmon and steelhead from extinction has way too long been mired in agency muck. Mr. Mainzer, General Helmlinger, Ms. Gray, and Mr. Mabe, you and we all know that the 2020 DEIS Preferred Alternative will also be castigated by the court. We all know the PA is designed to fail to recover Columbia Basin salmon and steelhead populations and is totally inadequate. We all know what these fish need for recovery. As so aptly put by Idaho's Representative Mike Simpson during a budget request hearing before a U.S. House of Representatives' subcommittee on Energy and Water Development on March 10, 2020, in Washington D.C.: "I noticed you all mentioned hydropower, irrigation and transportation and how important those are. Nobody mentioned fish. Nobody mentioned salmon that come back to Idaho, that in the next 15 years, if something isn't done, they will be extinct. There is no doubt about that, they will be extinct Any plan we come up with, any EIS had better recover salmon." Simpson added that the region has several options to replace the benefits of the dams, but the fish have only one option. "Those dams produce 3,000 megawatts of power. * You can put small modular reactors or other things in there. You can produce [power] differently. Everything we do, we can do differently. Salmon need one thing - they need a river."(Emphases added.) * While the four LSR dams have a nameplate capacity of 3033 aMW, they actually only produce an average of 1000 Megawatts. Over the last forty-eight years, the four dams, combined, have produced power to full nameplate capacity only on forty-six days. For the past nineteen years, their annual average has been 963 Megawatts. The submitted comments to the Army Corps of Engineers in late 2016 and early 2017 of approximately 400,000 members of the public, foretold the public's agreement with Rep. Simpson's March 2020 statements. A large majority of those comments urged the Corps to breach or remove the four lower Snake River dams in order to restore healthy populations of wild salmon and steelhead.	
3970	40	Shelley Silbert	Great Old Broads for Wilderness	4. The CRSO-DEIS Fails to Sufficiently Analyze and Factor into the Economics Picture the Steep Decline in Lower Snake River Transportation Waterway Freight Shipments. Continuing to ignore the above input with this current DEIS, the co-agencies find every excuse, every diversion from the fact that we humans have multiple options: like using other means of producing power- say, wind and solar, already existing and rapidly expanding in the Northwest and dramatically changing the Northwest energy sc ene. We also have options for replacing waterway transportation for cruise ships - say, buses and river tour boats with lodging/dining in Clarkston hotels and restaurants. We have options, too, for east/west freight. In fact, while in year 2000, the Port of Lewiston barged 17,590 TEUs of containerized freight, by 2017, container-on-barge shipping stood at zero. This steep decline began long before the Port of Portland closed its container operations in 2015 and was driven by the region's producers themselves. See Graph A below, Snake River Container Shipments by TEU, 2000-2017. [graph included in document Snake River Container Shipments] In 1995, the Port of Lewiston (POL) shipped 952,599 tons of wheat via the lower Snake River. By 2018, wheat volume had decreased by 332,013 tons, a drop of 35%. Today all wheat at the Lewiston port is shipped by the private corporation Lewis-Clark Terminal and over its own docks, not by the taxpayer-supported Port of Lewiston. See Graph B below displaying the wheat shipping decrease. [graph included in document Wheat Shipments by Ton] Total lower Snake River freight volume 2015-2018 averaged 2.64 million tons, a 40% decline since 2000. Paper, pulp, petroleum, pulse, logs and lumber are no longer shipped on the lower Snake - either by choice of the producers or, in the case of pulse, because containers are no longer shipped out of Port of Lewiston by barge. Grain shipping, too, has dropped as increasing numbers of grain growers shift to rail transport. The cooperatively operated McCoy Grain Loader on the Palouse Prairie serves as testimony to this fact. Of all freight shipped on the lower Snake today, 90% of it is grain, but, as you can see in Graph C below, volume of grain shipped has been in steady decline. [graph included in document Ice Harbor Lock Usage Report (Tons), by Commodity, 1999-2018] Regarding Graph C, note that freight locked through Ice Harbor Dam provides the most accurate measure of freight volume on the Lower Snake River Project (the 4 dams and their respective reservoirs). Freight shipped upriver on the Columbia River to the Port of Pasco, notably petroleum, travels a short distance on the Snake River but does not lock through any lower Snake dam. All waterborne freight to and from Lewiston, Idaho, passes through the lock at Lower Granite Dam. In 1994, 1,233 loaded barges were locked through Lower Granite. In 2017, just 314 were locked through - a decline of 75%. See below Graph D, Number of Loaded Barges through Lower Granite Lock, 1993-2018. [graph included in document: Number of Loaded Barges Through Lower Granite Lock 1993-2018] As the agencies know, the Corps classifies rivers by the number of ton-miles of freight (one ton of freight traveling one mile) a river carries each year. Annually: High use rivers transport 3+ billion ton-miles. Moderate use rivers transport 1-3 billion ton-miles. Low use rivers transport less than 1 billion ton-miles. The lower Snake River dams and reservoirs transport the next to the lowest freight volume among seventeen rivers in the Inland Waterways System. In 2014-2016, the annual average freight volume on the lower Snake totaled 0.28 billion ton-miles. If that volume tripled, the river would still be classified as a /ow use river. The truth is that compared to waterways throughout the United States, the lower Snake's importance as a transportation waterway is negligible. The Snake River transportation wat er way, to take this reality further, does not compare in any meaningful way to the importance of thriving anadromous fish populations to people, to rural economies, and to natural environments throughout the Snake River Basin. As of 2020, the probability of container shipping's return to the lower Snake River is zero. Freight transportation trends in the lower Snake River region make clear that the probability of the number of loaded barges increasing through Lower Granite locks is small. Thus, using lower Snake freight transportation as an excuse for allowing salmon and steelhead to go extinct is a false, unjustifiably expensive, and deeply amoral excuse. Were freight transportation via the lower Snake River a driver of prosperity in north central Idaho, as promised by the agencies and politicians when the four dams were first proposed in the 20t h century, or were freight volume increasing rather than steeply declining in the lower Snake waterway, the DEIS co-agencies may have valid reason to tout the necessity of these dams. However, prosperity and incr easing freight shipments have not and are not happening. See Graph E below, Growth of Jobs Since 1993. Mid-20th Century, agency and politician promises of prosperity due to dams was a false promise. Today it is a false premise upon which to base a decision to not breach the lower Snake River dams and a false premise upon which to not save Snake River Basin salmon and steelhead from extinction. [graph included in document: Growth of Jobs since 1993] Spanning 1993-2018, Idaho's job growth overall was 66%; but in Region 2, north central Idaho, job growth was 13%. In 2008, Region 2 averaged 42,645 employed workers. Ten years later, it averaged 41,858, a net loss of 787 jobs. Region 2 is the only region in Idaho that has not recovered from the 2008 great recession. Very likely, the decline in anadromous fish and concurrent fishing opportunities in north central Idaho are part of the reason for the region's inability to rebound. Any mid-20th-century forecast that Region2's "Inland Seaport," the Port of Lewiston, would usher in lasting prosperity was a disingenuous and false forecast. Downriver, in terms of a stoppage of barging, since Tri-Cities area farmers and others ship by barge on the lower Columbia River, their barging would be uninterrupted. Also, upriver-bound lower Columbia shipments of petroleum to Pasco would be unaffected by lower Snake breaching. Keep in mind, too, that about half of eastern Washington wheat growers already ship by rail. Also, an improved rail system from Lewiston downstream would further reduce (not expand) truck miles. New facilities needed for increased rail shipping could total $25-50 million, but this would be a one-time cost. Compare that figure to a yearly ongoing subsidy for barging of at least $25 million. Or to put it more simply: a subsidy per barge of at least $25,000. Northeast Oregon's local economies have suffered similar blows as Idaho's Region 2 related to declining anadromous fish runs. Greater Hells Canyon Council (GHCC) reports that in 2008, a sample year, fishers spent $12 million on fishing trips in Wallowa, Union and Baker counties. Salmon and steelhead were the target species for 110,000 fishing trips in eastern Oregon that year. Today local Oregon outfitters report significant declines in fishing business over	Access to barge transportation is the most cost effective means of accessing export markets for many of the grain producers in the Northwest currently, and removing that option would increase transportation costs for grain producers, as the EIS shows. This is different than container shipping, which the co-lead agencies agree is not currently occurring on the Snake River. It is true that barge movements on the Snake/Columbia river including grain and other commodities have declined over the past 20 years, but it also appears that the decline has stabilized over the past 10 years. The text of the EIS has been updated to describe how downriver shipment volumes have stabilized in recent years. While it is true that the Snake River freight volume is certainly smaller than the volume of the Mississippi and Ohio River systems, it is nonetheless an important transportation option for a large volume of freight, particularly for farm products, with the Columbia-Snake River system serving as one of the largest exporters of farm products in the U.S., and the largest exporter of wheat. The EIS analysis finds that transportation of freight that is currently barged on the lower Snake River could be accomplished via other transportation modes, but this change would not be without costs to farmers, would require public and private investment in infrastructure, and would result in some adverse regional economic effects, particularly in the short term. These effects are considered in the context of the overall objectives of the EIS. The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multi-objectives alternatives, including the effects on recreation (Section 3.11) and fisheries (Section 3.15). The EIS described the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the Lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. For MO1, MO2, MO4, and the Preferred Alternative, the recreational fishing evaluation describes the impacts by referencing the potential effects on relevant fish populations, as described in Section 3.5. Aquatic Habitat, Aquatic Invertebrates, and Fish, modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing and associated social welfare and regional economic effects would follow these changes in fish abundance. The social welfare values and regional economic effects associated with recreational fishing under the MOs, as well as river recreation post dam breach under MO3, were not estimated because of the uncertainty and large range in visitation and consumer surplus values among users. The comment incorrectly suggests that the EIS failed to consider replacing the lost generation from the various MOs, including MO3, which includes breaching the four lower Snake River dams, with solar, wind and other resources. For each alternative that reduced hydropower generation and regional power reliability, the EIS analysis estimated the amount of replacement power generation required to return the region to the reliability levels of the No Action Alternative (NAA). See Draft EIS, Section 3.7.3.1, Step 2: Analyze Effects on Power System Reliability; Appendix H, Power and Transmission, Section 2.1. That analysis considered both least cost and zero-carbon based resource portfolios. For example, for MO3, the EIS found that to return regional reliability to the same level as the NAA, either 1,120 MW of natural gas (least cost option) or 2,550 MW of solar (zero-cost option) would be needed. See Draft EIS, Section 3.7.3.5, Potential Replacement Resources and Associated Costs, on page 3-904. Thus, the EIS did show that the four lower Snake River dams generation could be replaced with new variable, renewable power. The costs of these replacement resources are also considered by the EIS, and provided for in each MO. For MO3, the range of rate pressure for replacement resources is provided in Section 3.7.3.5, Table 3-166 in the Draft EIS.

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
				the last fifteen years as runs continue their downward spiral. GHCC reports that at least sixty well paying rural northeast Oregon careers in watershed and fisheries management depend upon anadromous fish. Rural fishing-related economies are so vital to northeast Oregon that state and federal agencies funded 612 habitat restoration projects between 1995-2017, a taxpayer investment of more than $46 million. Yet now, the CRSO-DEIS co-agencies, through their Preferred Alternative are telling north central Idahoans, Oregonians, and Washingtonians engaged in fishing-related economies that their most abundant and continually renewable resource - salmon and steelhead - isn't worth saving. Northwesterners like us do not accept that position. The economic health of our rural fishing-related economies must be considered in any and all CRSO management alternatives. If considered, the weight of opinion will surely go to CRSO-DEIS Alternative 3 (MO3).	
3970	41	Shelley Silbert	Great Old Broads for Wilderness	5. The co-agencies Fail in Their Analyses to Acknowledge and Heed the Needs and Call of the People. The CRSO-DEIS speaks to the economic needs of farmers, barging companies, ports, and hydropower facilities, but ignores the above noted Idaho, Oregon and also Washington fishing related businesses and communities. Despite the availability of existing, publicly available data detailing elements of rural economies, in considering all system management alternatives and designating the preferred alternative, the co-agencies, astonishingly, did not account for the economies of recreation and fishing- guides, outfitters, motels/hotels, boat shops, restaurants, gas stations, license fees, convenience stores, grocery stores, pubs. Further, the co-agencies treat the costs to taxpayers of subsidizing barge shipments, supporting the non-shipping Port of Lewiston, and sustaining the aging, increasingly moot lower Snake River dams as inevitable far into a future that the co-agencies do not admit salmon and steelhead will not live to see - and fishing-related communities will not see - if the Preferred Alternative stands. The CRSO-DEIS also doesn't speak to the economic benefits of opening thousands of acres of riverside real estate for agricultural and other commercial, private, and community development. It doesn't speak of the economic benefits of dozens of riverbank habitat restoration jobs created due to breaching. Nor does the CRSO-DEIS speak of and ascribe value to the significant positive social welfare effects and just plain joy such habitat restoration would bring to Pacific Northwest Native Americans and thousands, if not millions, of other Americans . The above people's argument against the 2020 CRSO-DEIS Preferred Alternative is exemplified in a February 24, 2020, letter "written by leaders of small communities up and down the Clearwater and Salmon rivers that depend on salmon and steelhead fishing to fuel their economie s.83 Directed at Idaho Gov. Brad Little and all four members of the Idaho Congressional delegation, it pleaded for the leaders to "stop the downward trend of Idaho's salmon and steelhead toward ext inct ion." Also early 2020, PNW utility companies, conservation groups and even Port of Lewiston Manager David Doeringsfeld, wrote to the governors of Washington, Oregon, Idaho and Montana pleading for leadership. The coalition signers acknowledged that "Many Columbia Basin salmon and steelhead runs remain at risk of extinction and other fish and wildlife are threatened. The wellbeing of salmon is critical to our entire Pacific Northwest ecosystem, from the inland forests to ocean species," In their letter, they identified four shared goals - the first goal: "Abundant and harvestable fish originating in the Columbia River Basin are recovered." Clearly, it's time for the co-agencies to see beyond cement obstacles, aging turbines, barges, sediment removal, extraordinary fish mitigation costs which the co-agencies seem to carry as a banner of honor. This is the people's mandate to the co-agencies: Pacific Northwesterners demand a reversal of the devastation of our iconic, valuable resource: salmon and steelhead. To survive, these fish do not need barges and locks, cement and turbines. They need a river. In recent years, it has also come to light that the Southern Resident areas of the Salish Sea swim on the brink of extinction. Several factors play a role in their decline, but scientists have agreed, they're in decline primarily because of the loss of their key prey, Chinook salmon. Among Chinook runs vital to these endangered areas are Snake River Basin Chinook. In fact, the decline in Chinook populations resulting in a simultaneous decline in Southern Resident area viability moved Washington Governor Jay Inslee to request state funding for a "Lower Snake River Stakeholder Process." Recognizing the peril of both areas and Chinook, on February 19, 2020, forty-two Washington legislators sent a letter to Gov. Inslee in support of dedicating $750,000 for two years of funding for the stakeholder process. In February 2020, five scientists sent Northwest governors and Congressional delegations a document titled, "Southern Resident Killer Whales and Columbia/Snake River Chinook: A Review of the Available Scientific Evidence." In this document, the scientists state and demonstrate that"... substantial scientific evidence has highlighted the important relationship between salmon from the Columbia Basin, particularly Snake River Chinook, and the future survival of our critically endangered Southern Resident Killer Whales (SRKW or areas). Restoring healthy, abundant salmon to the Snake River is critical if we are going to provide a more adequate prey base for areas." On August 27, 2018, fifty-five "salmon scientists with decades of experience" wrote to to Governor Inslee and his Southern Resident Killer Whale Task Force co-chairs, Stephanie Solien and Thomas "les" Purce, to recommend "an Immediate Measure to Increase Columbia/Snake River chinook abundance." (acknowledging that the Southern Resident areas' key prey is chinook salmon) They recommended "total dissolved gas (TDG) levels up to 125% of saturation in the tailrace of each dam (without a forebay TDG limit) The evidence is compelling that the increase...will benefit salmon survival..." The scientists went on to recommend a "Permanent Measure ... the most effective measure we know of to permanently increase the sustained abundance of Chinook salmon from the Snake and Columbia Rivers: removing the four federal dams on the lower Snake River and restoring the ecological health of that river corri dor." 88 On February 11, 2020, Oregon Governor Kate Brown sent a letter to Gov. Inslee expressing support for exploring all possible solutions, including dam breaching, to the area and Chinook survival crisis. In her letter she expressed "her support to remove the earthen portions from the four concrete lower Snake River dams." She stated the science was clear - "removal is the most probable answer to salmon and steelhead population recovery in the Columbia River Basin, which could aid areas in their forage for fatty spring Chinook salmon off the mouth of the Columbia in late winter each year." 8 9 In April 2019, Idaho Governor Brad Little convened the "Governor's Salmon Workgroup" tasked to "Develop policy recommendations for Governor Little through a collaborative, consensus driven, public process to restore abundant, sustainable, and well distributed populations of salmon and steelhead in Idaho for present and future generations, while recognizing diverse interests throughout the St at e." 90 A group of Idaho elected and appointed officials, Chambers of Commerce, businesses and organizations wrote to Gov. Little and to Idaho's Congressional delegation members "to implore [their] immediate leadership to stop the downward trend of Idaho"s salmon and steelhead toward extinction. Once one of the largest migrations of anadromous fish in the world," they wrote, "Idaho's iconic fish are vanishing on our watch." 91 In other words, all three states and regional scientists are crying out for the recovery of their Northwest salmon and steelhead runs, a cry to which the CRSO-DEIS co-agencies remain deaf. The question arises: Why are the CRSO-DEIS co-agencies so dismally far behind the public, including scientists, on the salmon/steelhead issue? Why have the co-agencies not caught up with local-to-state Pacific Northwest officials who recognize that the 'status quo' Preferred Alternative is the wrong alternative for saving salmon and steelhead from extinction?	The EIS provides an evaluation of the social welfare and regional economic effects of the No Action Alternative and the multiple objective alternatives (MOs), including the effects on recreation (Section 3.11) and commercial fisheries (Section 3.15). The EIS describes the potential effects to recreational fishing qualitatively based on the evaluation in Section 3.5, Aquatic Habitat, Aquatic Invertebrates, and Fish. The co-lead agencies reviewed the research and literature that describes the economic contribution of recreational fishing in the middle Snake River above Lewiston to Hells Canyon Dam and in the Snake River tributaries, including the Salmon and Clearwater rivers. Anadromous fish conditions draw anglers to this region, bringing jobs and income to outfitting and tourism businesses and rural and tribal communities. Angler visitation can be highly variable from year to year depending on fishing closures, catch rates, bag limits, and fish abundance, among other factors. NMFS estimated that an average of 400,000 steelhead and salmon angler trips occurred in this region annually between 2002 and 2009 (NMFS 2014). Using a mid-point of $350 per trip, and assuming 400,000 salmon and steelhead anglers visit this region annually, angler spending or expenditures are estimated to be $140 million, $109.2 million is associated with non-local anglers. Expenditures by anglers from outside of the region are important to tourism businesses, outfitters, retail, and other businesses, bringing in economic stimulus to the region. These non-local angler trip expenditures are estimated to support 1,200 jobs and $45.2 million in labor income in this region. The action alternatives are anticipated to affect fish conditions, and in turn, angler visitation and spending, and regional economic conditions in Region C, which is described qualitatively. The potential for changes in recreational fishing of anadromous fish under MO3 in the Region C is described in Section 3.11. Increases in recreational fishing could support jobs, income, and social benefits in Tribal and rural river communities. For the effects on recreational fishing under MO3 (Section 3.11.3.5) along the lower Snake River below Lewiston, the evaluation considers fishing visitation in similar river reaches (e.g., Hanford River, Clearwater River) as an indicator for fishing visitation in this reach. The EIS describes that the visitation in the long-term in the lower Snake River, including recreational fishing, would likely offset short-term losses in reservoir recreation and possibly increase in the long-term compared to the No Action Alternative, supporting outfitting and tourism businesses in the region. The potential for changes in recreational fishing of anadromous fish under MO3 is described in Section 3.11, which could result in increases in recreational fishing in the long-term that would support jobs, income, and social benefits in Tribal and rural river communities. However, there is uncertainty around recreational fishing visitation in the long-term given the current measures to regulate, protect, and support ESA-listed fish populations and habitat in the region. For MO1, MO2, MO4, and the Preferred Alternative, the evaluation qualitatively describes the potential for effects associated with recreational fishing by referencing the potential effects on relevant fish populations, as described in Section 3.5. Fish modeling results vary for some of the alternatives, for example for the Preferred Alternative and MO4 (i.e., models show either beneficial or adverse effects to anadromous fish), so it is assumed that the potential changes in recreational fishing would follow these changes in fish abundance in the long-term. Co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. Moreover, the EIS analysis found only a minor effect to the Southern Resident killer whale would result from implementing MO3 (which includes the dam breach measure). MO3, the breaching of the Lower Snake River dams, found minor effect to SRKW. This is based on the following facts: The CSS and COMPASS modeling indicated a minor to major effect to spring chinook Smolt to adult returns. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults from the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built. NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up the majority of fish consumed by SRKW (NOAA BiOp 2020). The co-lead agencies note the contribution to the prey of Southern Resident killer whales through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan (LSRCP), which is administered by USFWS. Removing the Snake River dams alone will not recover the Chinook salmon to 1 million. The CFC did independent research that indicated that if dams were breached and the spill to 125% over the lower Columbia dams would "recover" the salmon populations. However, for the CRS that was not an alternative because it would not serve the obligations of the Lead agencies, including the Pacific Northwest Power grid. Combining breaching the four lower Snake River dams with spill up to 125% at the lower Columbia River projects is not a reasonable alternative under NEPA. For power and transmission, MO3 and Multiple Objective alternative 4 (MO4) individually each caused large loss-of-load probability (LOLP) results (i.e., increased incidence of blackouts). Without major additional new resources, MO3 would result in power shortages in about one in every seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. For reference, 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire U.S. by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4 and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. In the long-term, the co-lead agencies would likely not own or operate project lands after the projects are deauthorized under MO3. Project lands would be transferred through real estate actions, possibly to state or local government agencies. Because of the uncertainty regarding the ownership or management of the lands, no evaluation of the potential for land development was undertaken. If MO3 were selected, the Corps could use the CRSO EIS as a basis for seeking congressional authority to breach the four lower Snake River dams. After receiving both authority and appropriations from Congress, the Corps could initiate a detailed construction and design report for the breach measure, identification of disposal areas, real estate acquisition and disposal, permits, and mitigation requirements, including temporary fish hatchery production. Each of these actions are required prior to breaching, and the Corps does not have the authority or appropriations necessary to immediately breach the project's embankments.
3970	42	Shelley Silbert	Great Old Broads for Wilderness	6. Several CRSO-DEIS Statements and Implications Mislead and Misinform the Public. For example, let's remember that although the co-agencies and special interests speak of the "Columbia-Snake System" as single unit, and as if breaching the 4 dams would shut down all freight transportation in "the system," below Ice Harbor Dam, all waterway transportation and irrigation would continue as usual. This fact needs to be publicly stated. Let's also remember that grain and other products emanating from Idaho's Region 2 can be shipped via truck-rail, and negotiated agreements can be made to set ceilings on rail transportation costs, or the rail line from Lewiston to Ayer Junction (near Pasco), where it connects with the Union Pacific or BNSF rail lines, could be purchased. Such rail line purchases have occurred before in Washington, where the state bought three short lines under the Washington Department of Transportation's Grain Train Program. In other words, these are not unsolvable problems ... nor is salmon/steelhead survival endangerment an unsolvable problem. The co-agencies already have the solution in their hands: Alternative 3, breaching of the four lower Snake River dams, combined with a TDG level of 125% saturation at lower Columbia dam t ailraces .	The EIS does not assume that barge volumes would decrease substantially on the Columbia River as a result of MO3. The outcomes of the flows that end up on the Columbia River terminals are the product of all shippers in the area minimizing transportation costs and vary by rail rate increase scenario. Under scenario 1 (Effects of Dam Breach on Grain Transportation Assuming Constant Rail Rate), Columbia River barge transportation would continue to be important in the region downstream of Pasco under MO3, representing 32 percent of all grain moving to export (compared to 65 percent under the No Action Alternative). Grain transported on the river is assumed to arrive via truck. Under scenario 2 (Effects of Dam Breach on Grain Transportation Assuming Rail Rate Increase of 25 Percent), the EIS finds that the distribution of volume moving via different transportation modes would change substantially under this scenario, as the increase in rail rates would shift grain shipments away from shuttle rail lines to a combination of truck and barge. In Scenario 2, the total volume moving by shuttle rail to export ports would be 120 million bushels, a 67 percent increase from the No Action Alternative and a decrease of 14 percent from Scenario 1. The total volume moving by barge, 83 million bushels, decreases from the No Action Alternative estimate of 131 million (a decrease of 37 percent) and increases from the Scenario 1 estimate of 64 million (an increase of 29 percent). Note, river ports still operating on the Columbia River at Pasco, Washington, would experience a large volume increase, mostly from shipments arriving via truck traveling longer distances to access the river ports. As previously indicated in responses to similar comments from your organization, the agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% total dissolved gas (TDG) at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative; thus, it was not proposed as an alternative.
3970	43	Shelley Silbert	Great Old Broads for Wilderness	Conclusion Regarding Southern Resident Orca Survival Breaching the four Lower Snake River Dams (LSR Ds), according to the CSS modeling, would result in an estimated four times increase in the return of Chinook salmon within a few years. Consequently, independent SRl<W scientists have concluded that breaching the four LSRDs is the best, and likely only, way to recover SRl<Ws. "When all of this evidence is taken into account, we believe that , as a matter of scientific evidence, it is clear that lower Snake River restoration, including dam removal, is the single biggest and most effective step we can take to restore these two important species. The evidence of continued decline for both areas and Snake River Chinook also highlights the great urgency to take this action as soon as possible." Accordingly, the Co-agencies should revise the BA to determine that the Preferred Alternative will adversely affect the SRl<Ws, and instead implement a combination of LSRD breaching under MO3, plus 1 25% TOG spill at the 4 lower Columbia dams under MO4. This is the best and likely only ecological option that offers a near -term , meaningful route to recover this critically endangered species.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy species habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species. The overall health and condition of the Southern Resident Killer Whale (SRKW) depends on the availability of a variety of fish populations throughout their range. SRKW are Chinook specialists, but also consume other available prey populations while they move through various areas of their range in search of prey. NMFS and WDFW have developed a prioritized list of Chinook salmon within their range that are important to SRKW, to help prioritize actions to increase prey availability for whales (NOAA and WDFW 2018). This list includes many Columbia River Basin Chinook salmon stocks including Lower Columbia fall run (Tules and Brights), Upper Columbia and Snake fall-run (Upriver Brights), Lower Columbia River spring-run, Middle Columbia River fall run, and Snake River spring/summer-run. Southern Residents also are known to eat some steelhead, coho, and chum salmon, and halibut, lingcod, and big skate while in coastal waters. The diet is dominated by Chinook salmon both in coastal waters and within the Salish Sea; SRKWs are opportunistic feeders that follow the most abundant Chinook salmon runs throughout their range from the west side of Vancouver Island to the central California coast. There is no evidence that SRKWs feed or benefit differentially between wild and hatchery Chinook salmon. Snake River spring/summer Chinook salmon is a small portion of SRKW overall diet, but can be an important forage species during late winter and early spring months near the mouth of the Columbia River (Ford 2016). The co-lead agencies agree that the quantity and quality of prey is one of the limiting factors identified by NMFS in recovery of SRKWs, along with vessel traffic and noise, and toxic contaminants. The operation of the Columbia River System directly affects Chinook salmon, both wild and hatchery origin fish, which migrate past these federal dam and reservoir projects, and the associated effects would indirectly affect SRKWs. However, according to NMFS, in terms of the overall abundance of Chinook salmon available to SRKW for prey, numbers of adults form the Snake River Basin (including both hatchery and wild produced fish) are now greater than they were in the 1960s, before three of the four lower Snake River dams were built.

					NMFS maintains that hatcheries produce more than enough Chinook salmon in the Columbia River basin to offset losses caused by the dams. So far as researchers can determine, SRKW do not distinguish between or benefit differentially from hatchery and wild fish. Hatchery fish today likely make up most fish consumed by SRKW (NOAA BiOp 2020). Additional details on the most crucial prey stocks for SRKW, as well as their population and range, is available from several fact sheets and videos available here: https://www.fisheries.noaa.gov/species/killer-whale#spotlight. For more information, visit this National Marine Fisheries Service (NMFS) StoryMap on SRKW: https://noaa.maps.arcgis.com/apps/Cascade/index.html?appid=3405e6637bf74e998d4ebe992c54f613. The co-lead agencies note the contribution to the prey of SRKW through the continued existence of their respective independent congressionally authorized hatchery mitigation responsibilities, including, but not limited to, Grand Coulee mitigation, John Day mitigation and programs funded and administered by other entities, such as Lower Snake River Compensation Plan, which is administered by the U.S. Fish and Wildlife Service (USFWS). The scientists from the Fish Passage Center (FPC) models predicted that breaching the four lower Snake River dams would result in an increase in about 100,000 adult Chinook salmon returning to the mouth of the Columbia River (see Section 3.5). The FPC has indicated that an alternative not analyzed in the CRSO, which includes breaching the four lower Snake River dams, along with increasing spill at the lower Columbia River projects to the 125% gas cap would result in about one million fish returns. This alternative was not analyzed in the CRSO EIS. Improving ESA-listed juvenile and adult anadromous salmonid conditions were two of the eight multiple objectives of the CRSO EIS. The agencies disagree, however, that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% TDG at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an altenative. For power and transmission, MO3 and Multiple Objective alternative 4 (MO4), individually each caused large loss-of-load probability (LOLP) results (e.g. increased incidence of blackouts). Without major addition of new resources, MO3 would result in power shortages in about one in seven years. MO4 would produce power shortages in about one in every four years. If MO4 were implemented, in addition to breaching the four lower Snake River projects as called for in MO3, then the LOLP would be even higher, with power shortages potentially occurring almost every year. Additionally, if these MOs were combined, in 5% of the years, the power shortages would average close to 1,000 MW in early August when the region might be experiencing a heatwave with particularly high demand for air conditioning. 1,000 aMW is about the average amount of power consumed by Seattle City Light. As shown in Section 3.7, MO3 causes an increase in power reliability concerns in the winter and the summer. MO4 increases power reliability concerns in the summer. Thus, the combination has the largest impact during the summer. The cost of zero-carbon replacement resources for MO3 and MO4 individually are up to $1 billion/year. Resource replacements and associated transmission interconnections for the combination of MO3 and MO4 would be higher, though not likely as high as the sum of the two MOs individually. Assuming that the replacement resources consist largely of wind, solar, and batteries, this would require well over 50 square miles of solar power (more than two and a half times the size of Crater Lake), large areas of new wind generation, and unprecedented amounts of batteries (more batteries in the Northwest alone than the total projection of batteries expected in the entire US by 2023 per the Energy Information Administration). In addition, the reduced generation capability under MO3, particularly throughout the summer, in combination with the impacts of the measures in MO4, and the uncertainty about the characteristics of replacement resources, would result in less capability to provide voltage support and dynamic stability for transmission system reliability than under MO3 or MO4 individually. Thus, combining MO4 with breaching the four lower Snake River projects, would produce unreasonable power and transmission reliability impacts, and it is highly speculative that replacement resources could be sited, permitted and built to address these impacts. Thus, an alternative combining juvenile fish passage spill up to 125% and breaching the four lower Snake River dams is unreasonable, and thus was not proposed as an alternative.
3970	44	Shelley Silbert	Great Old Broads for Wilderness	One other distinction that needs to be made between the lower Snake's four dams and "the system's" other dams has to do with flood risk and management. In several places, the DEIS notes the importance of the system's dams for flood management. Quoting from the Executive Summary (p. 16) (Development and Comparison of Alternatives; Purpose and Need for Action): "The U.S. Congress authorized the Corps and [Bureau of] Reclamation to construct, operate, and maintain the system projects to meet multiple specified purposes, including flood control (also referred to as flood risk management) ... though not every project is authorized for every one of these purposes." The ES states that the PA " ...ensures that human life and safety can be protected through flood risk management." However, in the case of the lower Snake River, we are not talking about dams designed for flood control. The four lower Snake dams are run-of-the-river dams with little reservoir space for fluctuating water levels and with virtually no storage capacity, excepting perhaps a few hours of storage during peak flow. In fact, in Lewiston, Idaho, at the confluence of the Snake and Clearwater rivers, a levee exists to prevent overflooding from the reservoir. A few years ago, Lewistonians raised a ruckus over the possibility that the city's already imposing levee would need to be built higher due to possible reservoir overflow caused by sediment buildup at the Clearwater-Snake confluence. Indeed, build-up of sediment at the confluence is a continuous and costly problem that creates - as the rivers rise -flood risk for Lewiston. In 2012, for example, the prospect of needing a 3-foot higher levee created a community controversy in which community leaders strongly opposed raising the levee, one of whom said, "higher levees would further cut off Lewiston from its historic waterfront." "[Then] Lewiston Mayor Kevin Poole said dredging should be the first tool used to alleviate flood worries, and other actions should be favored over levee raising. 'Lewiston and Clarkston both always had a connection to the river,' he said. 'To put that barrier [a higher levee] there to me just doesn't make sense when there are some other things that they can do engineering-wise to handle the flood hydraulics." ' In response to the controversy, the U.S. Army Corps of Engineers opted to not raise the levee, but to "guard against long-term flood risks caused by the accumulation of sediment in the slackwater of the Snake River. The agency's 1000-page Programmatic Sediment Management Plan and environmental impact statement called for dredging at the ports of Lewiston and Clarkston and in the shipping channel of the lower Snake and Clearwater rivers." 93 Just to prepare the plan, the Corps spent more than 8 years and $16 million. Additional costs (also in the millions) accrued during the public review and final writing and adoption of the plan. In an April 8, 2013 interview with Boise State Public Radio reporter Aaron Kunz, the principal Corps spokesperson for the sediment management plan, Bruce Hendrickson, stated that the Corps needed $39 million from Congress before the Corps could begin work on the dredging project, as that was the cost of what the Corps planned to do. The bottom-line regarding flood risk and control is that the four lower Snake dams do nothing to prevent flooding at Lewiston-Clarkston or downstream but do create flood risk. With the Lewiston levee already built, landscaped and maintained, breaching of the lower Snake Dams would gradually yet relatively quickly eliminate sediment buildup, flood risk at Lewiston Clarkston, and the costs of continuously needing sediment dredging. In 2015, the actual cost to dredge 400,000 cubic yards of sediment from the navigation channel alone in the Lower Snake and Clearwater rivers near Lewiston-Clarkston (partly due to delay) was $9.9 million. 95 As the saying goes, "If you find yourself in a hole - particularly if it's filled with disappearing money, stop digging." Yet the Corps intends, at taxpayer expense and (currently) an invalid rationale, to keep on digging. The Great Old Broads for Wilderness urges the Corps of Engineers to toss its flawed rationale, and by doing so, save taxpayer money and reduce flood risk. It's time to "prefer" CRSO-DEIS Alternative 3, preferably combined with a TDG level of 125% saturation at the 4 lower Columbia dams.	The lower Snake River dams are not authorized for flood risk management as stated in the EIS in Section 1.2 of the EIS. Section 3.9, Section 7.7.11, and Table 7-1 indicate that there is no elevated risk to flooding in the Lower Snake River reach for any of the EIS alternatives. The Lower Granite reservoir is drawn down during high water events to ensure water levels remain low. Additionally, the Walla Walla District constructed eight miles of levees around Lewiston as part of the Lower Granite Project to help protect lives and property from potentially destructive high-water conditions after the dams were built. The most recent dredging in the Lewiston area has been to maintain a 14-foot depth in the Federal navigation channel, as discussed in the 2014 Programmatic Sediment Management Plan (PSMP). Although flood risk management is not an authorized project purpose of the lower Snake River projects, ensuring adequate flow conveyance through the Lewiston levee system supports the original Lower Granite Project design and all associated project purposes. Dredging outside of the navigation channel limits to maintain conveyance capacity has not been conducted since 1992. Dredging for channel conveyance capacity would only occur in the future if there were an observed accelerated rate of sediment accumulation and a heightened risk of levee overtopping, which does not appear to be the current trend. The PSMP identified the raising of the Lewiston levees up to three feet in selected areas as a potential system management option to manage flood risk, however this has not been evaluated further since the PSMP ROD. Channel capacity has been lost since the Lower Granite project was constructed, as early dredging efforts were not able to maintain the original capacity. However, provisional analyses described in the PSMP (Chapters 10-12) indicate that some segments of the channel in the upper reach of Lower Granite Reservoir are tending towards a state of relative morphological equilibrium under the prevailing sediment loads and discharges. Under the current flood control operations of Lower Granite Dam, during large flood flows, fluvial sediment transport processes were predicted to form an approximate equilibrium channel that maintains the conveyance capacity of the upper reach of Lower Granite Reservoir. During equilibrium sediment transport, the hydraulic conditions are great enough that sediment erosion balances sediment deposition so that there is no net change in the equilibrium depth of the channel segment. At even higher velocities, if sediment loading remains constant, the rate of sediment erosion will exceed deposition and a channel Section will tend to erode to reestablish a new deeper equilibrium depth. Sediment eroded from the confluence area was predicted to transport into the deeper reservoir reach downstream of Silcott Island where it has less effect on the flood stage at the Lewiston levees. According to the PSMP, levee capacity is predicted to remain adequate into the future. Modeling and monitoring of sediment accumulation were recommended in the PSMP for determining if/when channel conveyance dredging is required to maintain capacity, rather than attempting to maintain the original capacity, as was done during the early years of the project.
3970	45	Shelley Silbert	Great Old Broads for Wilderness	7. The CRSO-DEIS Fails to Take a Panoramic View of the PNW's Fast-Changing Energy Scene and to Account for an Increasing lack of Need for lower Snake Dam Energy Production. The fast-changing Pacific Northwest (PNW) energy scene also leads us to that same conclusion. As shown in Graph F below, the four lower Snake dams, combined, produce 3.3% of the PNW's power supply, and the PNW regional power surplus - with breaching of the lower Snake dams - would be 13.7%. For 2020, the projected regional load is 23,906 average Megawatts (aMW). Under critical water condit ion s, the projected generation in 2020 is 28,820 aMW, which leaves a surplus of 3,950 aMW - four times the average lower Snake production. In other words, were all four lower Snake dams breached, the PNW region would still have an energy surplus. [graph included in document Pacific Northwest Surplus Energy Relative to LSR Dams (1937 Critical Water Year)] [graph included in document: PNW Region Variability of Annual Hydro Generation OY 2020 through 2029 Under Different Water Conditions] Although the DEIS Executive Summary states that "Significant quantities of replacement resources would have to be built to maintain regional power reliability" or "the region would face the likelihood of a loss of load event, e.g. a power blackout, nearly one in every seven years in M03 ...," Graphs G above and H below suggest otherwise. First, the lower Snake power output is not particularly significant, nor are blackouts under any circumstances related to lower Snake output likely. This is especially true if one considers the already occurring energy efficiency gains, spoken of further below. Additionally, BPA's Strategic Plan calls for the export of surplus power. However, for that disappearing power too, there is a solution: don't export surplus power. Also, at the pace energy innovations are happening today, such as battery storage innovations, brownouts and blackouts will become even more rare. The 1937 "critical water year" represents the lowest recorded river flow; 1958 the "average water year;" and 1974 the "high water year." The amount of hydropower generated in any given operating year depends upon the volume of available water in the rivers. Bonneville Power Administration uses 1937 water levels in its energy forecast - understating, in effect, the volume of surplus power that will likely be available much of the year. But Graph G above shows variability in annual hydro generation projections for operating year 2020 through 2029 under different water conditions. That variability can alter the amount of PNW energy surplus, as shown in Graph H below. [graph included in document; Pacific Northwest Surplus Energy Relative to the LSR Dams 1958 Water Year] During an average water year, PNW surplus energy increases by an estimated 3,779 aMW, nearly four times the average output of all four lower Snake dams, combined. A high water year would produce an additional 3,127 aMW, more than three times the average output of all four dams, combined. In other words, the use of the critical water year, 1937, for power projections consistently underestimates the amount of surplus energy in the Pacific Northwest. According to the Corps of Engineers' Data Query website, the lower Snake dams 2004-2019 average annual Megawatt production was a mere 963 aM W.99 Thus, we reit erat e: Were all four lower Snake dams breached, the PNW region would still have a more than sufficient energy surplus. There would be no cause to fear any of the special-interest hyped power "blackouts." [graph included in documents: Seven Year Plan Resource Portfolio] In fact, the PNW could see that surplus grow higher due to efficiency gains. As shown in Graph I above, the Northwest Power and Conservation Council (NWPCC) projects additional power resulting solely from efficiency gains in 2020 will be 1000 aMW, slightly more than the above 2004-2019 annual output of the four lower Snake dams. In the DEIS Executive Summary (p.25), the co-agencies state that Alternative 3 (MO3) "would not meet the objective to Provide a Reliable and Economic Power Supply. Under MO3, hydropower generation would decrease by 1,100 aMW under average water conditions, and 730 aMW under low water conditions compared to the No Action Alternative. "	The EIS acknowledges that the energy sector is constantly undergoing transformation and that technological improvements will likely bring other options. To avoid speculation, the EIS analysis focuses on primary technologies identified by the Northwest Power and Conservation Council (Council) in their 7th Power Plan (page 13-5) that are deemed proven, commercially available, and deployable on a large enough scale in the Northwest. The EIS also examined the use of storage technologies considered a long term resource of the Council's 7th Power Plan, but has become more commercially available since the release of the 7th Power Plan, and will now likely be considered a primary resource in the Councils 8th Power Plan. The comment suggests that the regional supply of power is sufficient without the output of the four lower Snake River dams, and even sufficient without replacing the output of the lower Snake River dams with other resources. The comment reaches this conclusion by comparing the average resource output for the remaining regional resources (without the four lower Snake River dams) with average load in the region. Such an approach, however, only demonstrates that on average that is under average conditions - all power system needs would be met. This approach does not address conditions other than average. That is, regional demands for power would not be met at times of greater than average load or lower than average resource output. In those instances, power system emergencies or blackouts would occur. The EIS uses a more robust measure of power system reliability and resilience than the average MWs approach suggested by the commenter. Specifically, the EIS uses the loss-of-load probability (LOLP) metric utilized by the Council. See Section 3.7.2.2; Appendix H Power and Transmission, at Section 2.1 and Appendix I Hydroregulation, Section 2.4.4 in the draft EIS. The LOLP metric evaluates the adequacy of power supply in the region to meet firm power needs under various conditions. It is measured in terms of a percentage, and represents the likelihood of a blackout occurring in a year. See Appendix H Power and Transmission, at Section 2.1 in the draft EIS. The current LOLP under the No Action Alternative is 6.6 percent; this is equivalent to one blackout in every 15 years. The EIS uses this LOLP level as the benchmark from which to gauge the other Multiple Objective (MO) Alternatives. Under MO3, on average, the region has surplus generation leading to export sales during certain periods and water years. Nevertheless, to maintain regional reliability at the LOLP levels of the No Action Alternative, replacement resources would be needed. This is driven by the timing and magnitude of changes in hydropower generation analyzed in the EIS. As shown by the analysis of the LOLP, in some years and times of the year, particularly winter and later in the summer of drier years, without the four lower Snake River dams there would be insufficient power supply in the region leading to power emergencies and blackouts. Specifically, without replacing the power from the four lower Snake River dams, the LOLP of the region would more than double to 14 percent, which is equivalent to one blackout every seven years. See Section 3.7 in the draft EIS at page at 3-903 and Appendix H-Power and Transmission, at Table 2-1. The commenter also presumes that the power produced from the four lower Snake River dams is surplus and exported out of the region. The power output for the four lower Snake River dams are not exclusively sold as surplus as the commenter suggests. Bonneville sells power from the Federal Columbia River Power System (FCRPS) as a unified system, not from specific projects. In this regard, the power generated from the four lower Snake River dams are pooled with all other FCRPS power sold by Bonneville to meet Bonneville's collective power obligations. Most of this power is used to meet the loads of regional publicly owned utilities, such as municipalities, rural utilities, and public utility districts under long-term power-sales contracts (see Section 3.7.2.5 Bonneville Power and Transmission Customers in the draft EIS). A small portion of power is sold in the California energy market, but these sales are not from specific projects, but rather from the collective FCRPS. The comment suggests that the main benefits of the four lower Snake River dams are the average annual energy output these resources produce. While an important supply of actual power, these projects also provide generating capability that is critical to power system reliability function. As explained in Section 3.7.3.5 of the draft EIS, Potential Replacement Resources and Associated Costs, breaching the four lower Snake River dams would have a direct and substantial impact on the supply of Federal power to meet regional load requirements. These impacts would affect both actual energy to meet regional load requirements and generating capacity (peaking capacity) to meet variability in loads. The comment suggests that the output of regional resources are being underestimated because of the practice of using critical water assumptions for purposes of determining the available supply of power. However, the EIS power reliability analysis does not assume only critical water when determining the effects of the No Action and MOs on LOLP. Instead, the EIS relies on the full range of potential water years (including average water), not solely the critical water year as implied by the comment. Again, the timing and magnitude of changes in power supply and demand are important to consider not solely the total surplus in the region as provided in the comment. The profile of hydropower generation is described further in the draft EIS in Appendix J and the volume of surplus sold by Bonneville under each MO is described in Appendix H, Chapter 4 Power and Transmission Rates. In the rates analysis accompanying each MO, Bonneville does use critical water as an input to determining the power rates. Using critical water year assumptions for power planning and analysis is a well-established and long-standing practice in Bonneville ratemaking. Because the fuel of a hydropower system (water) is variable and unknown, Bonneville uses the minimum amount of power that may be expected in an adverse year to set its firm power obligations for rates. This metric,

Letter No.	Comment No.	Commenter Name/Email	Affiliation	Comment	Response[1/]
					while not a guarantee, creates a high degree of likelihood that the firm power obligations will be met with the existing hydropower system, minimizing the need to assume and forecast unnecessary and costly acquisitions. See Sections 3.7.2.5, 3.7.2.7 in the draft EIS. As the commenter notes, greater than critical water typically occurs. In these years, the additional power is sold as secondary or non-firm power. See Section 3.7, page 3-801 in the draft EIS. Projected sales from secondary power is included in Bonneville's rates, which is based on average water conditions across 80 water years of record. Finally, the EIS power analysis included all cost-effective conservation identified by the Council in the load forecasts analyzed in the power analysis (Section 3.7).All cost effective conservation identified by the Councils 7th Power Plan is included in the load forecast. Under Washington and Oregon law, all cost effective conservation must be acquired regardless of the status of the FCRPS. Therefore, conservation was not considered a potential resource replacement. The EIS analysis considers that all energy efficiency assumed in the Councils 7th Plan is appropriate and, likely, aggressive. The Councils recent State of the Columbia River System, Fiscal Year 2019 Annual Report, February 2020, p. 11 (https://www.nwcouncil.org/sites/default/files/2020-3.pdf), states While the region currently is on track to meet Seventh Plan goals, there are some areas to watch including forecasts of declining savings from efficiency programs. And whether the region will identify new savings opportunities to replace those of residential lighting. Utilities achievements in energy efficiency have been on an annual decline since 2016. Forecasts from utilities show that this trend is expected to continue, despite relatively stable funding levels. Given this trend, there is some uncertainty as to whether there will be enough savings from other mechanisms to reach the 1,400 average megawatt goal by the end of Fiscal Year 2021. This information indicates that it would be difficult to increase the energy efficiency goals beyond the Councils Plan. Based on this information, it is not likely that substantial amounts of additional energy efficiency would be available as prices increase, such as in MO3.
3970	46	Shelley Silbert	Great Old Broads for Wilderness	However, if the NWPCC efficiency-gain projection above is correct, as we believe it will be, Alternative 3, including breaching, would meet the DEIS systemwide objective: Provide a Reliable and Economic Power Supply. It follows, too, that efficiency gains will diminish the role the dams play in maintaining reliabilit y, flexibility and dispatchability, and diminish their effect on the region's risk of power shortages compared to the No Action Alternative. Efficiency gains would also then lessen any need for "significant quantities of replacement resources," and thereby, also save taxpayer dollars. The entire notion of a need for "significant quantities of replacement resources" with regards to power is dubious since that "need" is so minimal ... or nil ... and is, importantly, an already underway solvable "replacement" problem.	The EIS power analysis included all cost-effective conservation identified by the Northwest Power and Conservation Council (Council) in the load forecasts analyzed in the power analysis (Section 3.7). All cost effective conservation in the region is assumed to be acquired consistent with existing law and mandates regardless of the status of the four lower Snake River dams. The Council estimated available efficiency gain projection, then, is not a potential replacement resource for the lost capability from the four lower Snake River dams. To maintain regional reliability at the No Action Alternative levels, other types of replacement resources are needed. Appendix H, Section 2.2.2 in the Final EIS provides additional details regarding efficiency and the selection of replacement resources.
3970	47	Shelley Silbert	Great Old Broads for Wilderness	The CRSO-DEIS Pr efe rred Alternative fails on both the fish and power fronts. That is, it fails to ensure achievement of a needed average of 4% or higher smolt-to-adult return ratio (SARS) for run recoveries and fails to include PNW power surplus and power savings projected to be accomplished by increasing power usage efficiency, both of which render the four lower Snake dams moot. The PA's goal of ensuring "adequate, affordable and reliable power" (ES, p.32) will be fully met by Alt ernat ive 3; that is, breaching of the 4 lower Snake dams will not unhinge the meeting of that goal. Only Alternative 3, including breaching, will ensure an SAR of at least the needed average 4% baseline for fish run recoveries. [graph included in document: Balancing Authority Load & Total Wind, Hydro, Fossil/Biomass, Nuclear Generation, and Net Interchange] March 2019, 7-day BPA Power Generation Historically, BPA's revenue stream relied in part upon the sale of surplus energy. Today, however, due to fast-paced development of other energy sources in places such as California to which BPA previously sold surplus at a profit, BPA's surplus power is no longer in high demand. BPA now is, in fact, compelled at times to sell the Northwest's surplus power at negative prices. There are times today, too, such as during spring run-off, when surplus power significantly increases, and that increase causes BPA to reduce or shut down wind and other power sources as per its "Oversupply Management Protocol." Indeed, at times, as shown in Graph J above, BPA's combined power generation reaches a level approximately twice as great as its contracted power demand.	Contrary to the statement in the comment, the loss of the power generated from the four lower Snake River dams has adverse effects on regional power reliability and increases power costs. See Draft EIS at page 3-903 (describing the effect of MO3 on power system reliability); Section 3.7.3.5, Table 3-166 (describing power rate impacts of MO3 and a potential 40 percent increase above the No Action Alternative). For these reasons, and others stated in the EIS, MO3 was found to not meet the objective of ensuring an adequate, economical, efficient and reliable power supply. The statement that Bonneville revenues include the sale of surplus energy is accurate; however, Bonneville surplus power is still in demand and sold regionally and exported beyond the region, when available. If the output of the four lower Snake River dams is removed, then Bonneville would have less firm power (used to serve regional utilities) and less surplus power to sell. The rate pressure impacts of this outcome are described in Section 3.7.3.5, Table 3-166, Draft EIS. The comment notes that Bonneville sells surplus power during certain months of the year. However, Bonneville's firm power obligations are determined by the load placed on Bonneville throughout the year. These loads tend to be winter peaking, meaning the extra surplus produced in spring does not assist in meeting these firm obligations. Regarding oversupply management protocol and negative prices, it is Bonneville policy not to bid on negative market prices. It should be noted that the 4% Smolt-to-Adult return rate (SARs) target referenced throughout this comment refers to the Northwest Power and Conservation Councils (Council) target for broad-sense recovery and is separate and distinct from the obligations of any single entity or in this case a requirement to be met solely by the co-lead agencies. Just as the Councils fish and wildlife program encompasses both Federal and non-Federal stakeholders in the Columbia Basin, the Councils recovery goals are shared by many parties. However, the Councils broad sense recovery goals are beyond the scope of this EIS which contemplates the effects associated with the operation and maintenance of the 14 CRS projects. The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. As of the time of the release of the Draft EIS, the co-lead agencies were in consultation with the National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS) on the effects of the proposed action on ESA-listed species. The Final EIS includes the final Biological Opinions in Appendix V. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4 for the Preferred Alternative, the co-lead agencies anticipate that the Preferred Alternative would provide benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. The CSS model predicts that average Smolt-to-Adult return rates would increase for both Snake River spring Chinook and steelhead and will average above 2% (the lower end of the Northwest Power and Conservation Councils recovery targets for the region) as a result of the Preferred Alternative, increasing from 2.0% to 2.7% for Chinook, a 35% relative increase. The National Marine Fisheries Service COMPASS and Lifecycle Models predict higher levels of risk associated with increased spill levels in the absence of offsets from decreased latent mortality. The Preferred Alternative will be implemented using a robust monitoring plan to help narrow the uncertainty between the two models and to determine how effective increased spill can be towards increasing salmon and steelhead returns to the Columbia Basin. See Appendix R, Part 2 Process for Adaptive Implementation of the Flexible Spill Operational Component of the Columbia River System Operations EIS for additional information.
3970	48	Shelley Silbert	Great Old Broads for Wilderness	Currently, around the world, many developments in the arena of power generation lean toward power storage capability. Yet, the 2020 CRSO DEIS co-agencies apparently remain blind to the possibility that researching or creating and building storage facilities for surplus power and/or oversupply would be a more innovative, much less expensive, more consistently reliable, and finally, for the planet's sake, more resource friendly investment than continuing tax payer funded expenditures in support of the four aged and no longer essential lower Snake River dams. We suggest that the co-agencies designate Alternative 3, including breaching plus a 125% TDG spill at the lower Columbia tailraces, as the "preferred alternative" and add a "power storage development" component to that alternative.	The EIS analysis identified the most cost-effective resources to replace lost capability from the four lower Snake River dams. Battery storage alone, however, was not identified as independently cost effective as a replacement for the hydropower generation of the lower Snake River dams. However, the EIS did identify some potential benefits of storage technologies when coupled with another resource such as solar. Consistent with the commenters suggestion, a resource portfolio using both solar and battery technology is considered in the resource discussion of MO3. See Section 3.7.3.5, pages 3-905-910 in the Draft EIS. The EIS acknowledges that technological improvements will likely bring other options. See Section 3.7.3.5, page 3-907 in the Draft EIS. As previously indicated in responses to similar comments from your organization, the agencies disagree that an alternative that includes breaching the four lower Snake River dams and spring spill operations to 125% total dissolved gas (TDG) at all four lower Columbia River dams is reasonable given the unacceptable risks to public safety from such an alternative; thus, this alternative was not proposed for analysis.
3970	49	Shelley Silbert	Great Old Broads for Wilderness	Indeed, lower Snake dam breaching itself could leave infrastructure in place that may provide a foundation for an up-to-date power-savvy approach, such as development of a power storage facility. According to Wood Mackenzie, the global energy storage business will have a record year in 2020, with 12.6 gigawatts of battery storage to come online. 1 02 The CRSO-DEIS co agencies could become a party to that growt h. Both breaching and storage development would create needed new jobs. Consider too that, since the federal government owns the dams and transmission lines, the government is competing with private enterprise, which discourages, rather than encourages, development of new sources of PNW energy. For example, with wind projects, farmers benefit by leasing land to wind pro jects; local government and state taxes are paid; and wind project developments create both short-term (construction) and long-term (operation) jobs. The co agencies have an opportunity right now to leap t o the forefront of the power storage or power production frontier with a "Pacific Northwest Breach-and-Build Power Project." For the fish, "right now" is all the time they- and we - have. "We've taken huge hits in the secondary revenues market, with cheap gas, low load growth, and the oversupply conditions. It's been a bloodbath for folks in the wholesale market." - Elliot Mainzer, Administrator, Bonneville Power Admin. We believe the above Elliot Mainzer statement, and we believe it's time to eliminate the lower Snake dams from BPA's wholesale market. Prior to 2009, the price of surplus power averaged about $60 per Megawatt hour (M Wh). Since 2009, the average price for surplus power has been about $22 per MWh. As reflected in Graph K below, when surplus power sold for about $60 MWh, power from the lower Snake dams had an annual market value of $506 million. In today's surplus market, that power would earn $186 million - a drop in revenue of $320 million. [graph included in document: COB Electricity Prices Avg. by Day, 2002-2017] In fact, the ongoing decline in prices for surplus PNW energy has created a fiscal crisis for BPA, as BPA Administrator Elliott Mainzer has publicly acknowledged. As shown in Graph L below, beginning in 2008, in reaction to its loss of revenues, BPA drew down its fiscal reserves from $917 million in 2007 to a fragile $5 million in 2017. BPA's own documents show that BPA needs $300 million for six weeks operating capit al. 104 In 2011, as shown in Graph L below, BPA began raising the price of power for its contracted Tier 1 customers. Over a period of eight years, price increases totaled 30%. There were no winners - not BPA, not Tier 1 ratepaying customers, and not taxpayers. Yet, here we have another solvable crisis. Alternative 3 could usher all three of the injured-and the Pacific Northwest's iconic anadromous fish - back into flow. [graph included in document: BPA TI PF Rate and Reserves 2006 - 2019] BPA's surplus energy revenue losses forced BPA to raise its price, so that its 2018-2023 strategic plan calls for selling more surplus power at higher prices into a falling market. See Graph M below. So what's the outlook? Public Utility Districts (PUDs) that purchase BPA power are under contract until 2028. BPA currently charges them $35.57 per Megawatt-hour (MWh) for firm (guaranteed) power. If BPA is unable to offer power at a competitive price, PUDs will reduce their power purchases from BPA or simply not renew their contracts. For BPA, that is not a good outlook. So is BPA going to be able to offer power at a competitive price? [graph included in document: Historical Priority Firm Power Rates FY2010-2019] FY 2018-19 market estimated with BP-18 Rate Case market price forecast. Pacific Northwest wind power plants produce nearly three times the output of the four lower Snake dams, combined. In Montana, new wind power projects are predicted by 2030 to produce up to 5000 aMW targeted for export to the Pacific West Coast states. Near Pendleton, Oregon, the Wheatridge project will include 292 turbines with a peak capacity of 500 aMW and includes wind, solar and battery backup to offer firm power at competitive pricing. As shown in Graph N below, wind power costs have, since 2010, fallen and become cost competitive with BPA's rate for firm contracted power. [graph included in document: Lazard Onshore Wind Cost Reports] As Graph O below shows, from 2010 to 2017, the average solar energy price declined by 76% to $38.50 per MWh. Between 2018 and 2023, California, once a major buyer of BPA's surplus power, intends to add 14,037 aMW of new solar energy to its own energy portfolio. Again, is BPA going to be able to offer power at a competitive price? Is keeping the aging lower Snake River's four dams going to sustain and/or bolster BPA's viability? From a taxpayer perspective, is it worth continuing to pay the costs associated with the lower Snake's four dams and the costs of mitigating their negative effects on anadromous fish survival? [graph included in document: I ,aza rci Solar Cost Renorts] Graph P below shows the distribution of BPA's hydropower system program costs. [graph included in document: Program costs]	The EIS acknowledges the potential future role and benefit of energy storage as described in the comment. For instance, the zero-carbon resource portfolio for MO3 includes solar resources coupled with storage technologies. See Section 3.7.3.5, pages 3-905-910 in the Draft EIS. The cost of this portfolio is also described in Section 3.7.5.3, Table 3-166 in the Draft EIS. The socioeconomic impacts of the rate pressure caused by the cost of these replacement resources on regional consumers and business is described in the social and economic effects section of MO3. See Section 3.7.3.5, page 3-928 in the Draft EIS. In addition, while the comment describes the opportunity for the co-lead agencies to lead on power storage and power production, as described in the EIS, Bonneville cannot directly own a resource and, can only acquire a major resource (greater than 50 aMW and longer than 5 years) after following a statutory process that involves input from multiple constituencies. In recent rate cases, Bonneville has implemented significant cost reductions which have bent the curve of cost increases while balancing the need to protect fish. Lower market prices on the wholesale power market have increased cost pressures by decreasing the value of net secondary revenues which serve as an offset to revenue requirement costs collected in rates charged to long-term power customers. The need for Bonneville to remain competitive is addressed in Bonneville's strategic plan, and Bonneville is on its way to executing that plan. While competitive pressures on the wholesale market are expected to continue, the Preferred Alternative is predicted to benefit ESA-listed salmon and steelhead and also meets most of the other objectives of the EIS for resident fish, lamprey, hydropower generation, water management, and water supply, while minimizing adverse effects to communities and the economy. In addition, as described in Section 3.7.3.5, Table 3-166, in the Draft EIS, the cost savings associated with the loss of the four lower Snake River dams would be offset by higher resource replacement costs, integration costs, and other cost pressures. The information from the comment regarding declining prices for renewable resources is consistent with historical trends. However, a projected future cost of a theoretical renewable portfolio is not enough information to determine its cost effectiveness relative to the four lower Snake River dams. For example, the specific capacity and reliability attributes of that portfolio must be considered as well as transmission costs and availability. Even if the physical characteristics were the same, and transmission available at the same cost, comparing the production cost of that potential future renewable portfolio to Bonneville's average wholesale rate is not an equivalent comparison. This is because roughly $9/MWh of Bonneville's average wholesale rate includes benefits to the region that would have to be added to the production cost of that renewable portfolio to make it more comparable. Specifically, Bonneville's average wholesale rate includes the cost of providing subsidies to utilities with higher average system costs (approximately $250 million annually), transmission costs associated with serving loads in other balancing authority areas (approximately $100 million annually), energy efficiency programs and incentives (approximately $125 million annually), subsidies to utilities with low densities (approximately $40 million annually), and subsidies to utilities with eligible irrigation loads (approximately $20 million annually).
3970	50	Shelley Silbert	Great Old Broads for Wilderness	From 2008 to 2017, BPA's cost for fish and wildlife mitigation in the Columbia Basin averaged $727 million per year, or about 24% of BPA's annual budget. Since 2001, the Corps of Engineers has spent at least $1.8 billion on "structural improvements" to lower Snake and lower Columbia dams in an attempt to increase juvenile fish survival. After 20-plus years and a cost of over $15 billion, no Columbia or Snake River threatened or endangered	Because structural changes to improve salmon and steelhead (e.g. spillway weirs) are in place at this point, there are few additional structural improvements proposed in the Preferred Alternative. Most of the structural improvements in the Preferred Alternative are focused on improvements for lamprey passage.

				salmon or steelhead species is on a path to recovery. Some swim on the brink of extinction. With the 2020 DEIS Preferred Alternative, the co-agencies are unconscionably proposing to continue their failed "structural improvements" routine well into the future. Despite BPA's predictable lack of fiscal reprieve, the ongoing downward trend of hydropower load demand, the significant loss and high expense of lower Snake waterway barging, and the agonizing continual decline of anadromous Snake Basin fish runs, "structural improvements" is all the DEIS offers ... a bottom-rung, least effective effort. Also, we must note that the recent agreement to increase spill to 125% total dissolved gas was intended to be a temporary lifeline for the fish, not a long-term fix.	The co-lead agencies are legally obligated to operate and maintain the CRS to meet multiple statutory purposes. They are also required to ensure operation of the CRS complies with other laws. Under the ESA, in particular, the operation of the CRS may not appreciably reduce the likelihood of ESA-listed species survival and recovery, or adversely modify or destroy designated critical habitat. The ESA does not, however, require the co-lead agencies to take affirmative actions to recover ESA-listed species as that is a broader goal with shared responsibility. Based on the fish analysis in Section 7.7.4, the co-lead agencies anticipate that the Preferred Alternative would provide substantial benefits to ESA-listed species and is not expected to diminish the likelihood of recovery. Recovery is a broader regional goal and is above and beyond the co-lead agencies obligations under Section 7(a)(2) of the ESA for the effects of operation and maintenance of the Columbia River System. Recovery of ESA-listed salmon is outside of the authority of the co-lead agencies, and was not an objective of this EIS. Recovery of ESA species is the purview of the National Marine Fisheries Service (NMFS) and the U.S. Fish and Wildlife Service (USFWS). This EIS has been developed in consultation with NMFS and USFWS to find an acceptable balance that allows the co-lead agencies to meet the Purpose and Need Statement while minimizing impacts to affected ESA-listed species and their habitats. Recovery efforts will need to continue to involve parties across the region that have an influence and impact on ESA-listed species. The commenter's suggestion that the flex spill operation is only planned for one year is not an accurate interpretation of the Preferred Alternative. The 2019-2021 Spill Operation Agreement was a short-term agreement that was intended to last until the Record of Decision for the CRSO EIS was signed. However, the fact that it was a short-term agreement did not preclude the co-lead agencies from considering the operation as a measure to include in the EIS. In fact, this operation would attempt to provide a high potential benefit to salmon and steelhead through increased spill while avoiding many of the adverse effects to power generation and reliability associated with Multiple Objective alternative 4. This measure also would allow the co-lead agencies to gather important scientific information on the relationship between the CRS and latent mortality. This measure would be managed adaptively, through the established Regional Forum processes, to address unexpected challenges, such as potential delays to adult migration, temporary operations needed to maintain navigation, and other challenges or opportunities that may require either a temporary or permanent change. If no adaptive management needs are identified, the operation would continue until modified by the co-lead agencies.
